- **PCTLDEF=2** observation numbered closest to \( np \)
  \[
y = x_i
\]
  where \( i \) is the integer part of \( np + 1/2 \) if \( g \neq 1/2 \). If \( g = 1/2 \), then
  - \( y = x_j \) if \( j \) is even, or
  - \( y = x_{j+1} \) if \( j \) is odd

- **PCTLDEF=3** empirical distribution function
  \[
y = x_j \text{ if } g = 0
\]
  \[
y = x_{j+1} \text{ if } g > 0
\]

- **PCTLDEF=4** weighted average aimed at \( x_{p(n+1)} \)
  \[
y = (1 - g)x_j + gx_{j+1}
\]
  where \( x_{n+1} \) is taken to be \( x_n \)

- **PCTLDEF=5** empirical distribution function with averaging
  \[
y = (x_j + x_{j+1})/2 \text{ if } g = 0
\]
  \[
y = x_{j+1} \text{ if } g > 0
\]
**Missing Values**

Missing values can be replaced by the location measure or by any specified constant (see the REPLACE option and the MISSING= option). You can also suppress standardization if you want only to replace missing values (see the REPONLY option).

If you specify the NOMISS option, PROC STDIZE omits observations with any missing values in the analyzed variables from computation of the location and scale measures.

---

**Output Data Sets**

**OUT= Data Set**

The output data set is a copy of the DATA= data set except that the analyzed variables have been standardized. Analyzed variables are those listed in the VAR statement or, if there is no VAR statement, all numeric variables not listed in any other statement.

**OUTSTAT= Data Set**

The new data set contains the following variables:

- the BY variables, if any
- _TYPE_, a character variable
- the analyzed variables

Each observation in the new data set contains a type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:

<table>
<thead>
<tr>
<th><em>TYPE</em></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION</td>
<td>location measure of each variable</td>
</tr>
<tr>
<td>SCALE</td>
<td>scale measure of each variable</td>
</tr>
<tr>
<td>ADD</td>
<td>constant specified in the ADD= option. This value is the same for each variable.</td>
</tr>
<tr>
<td>MULT</td>
<td>constant specified in the MULT= option. This value is the same for each variable.</td>
</tr>
<tr>
<td>N</td>
<td>total number of nonmissing positive frequencies of each variable</td>
</tr>
<tr>
<td>NORM</td>
<td>norm measure of each variable. This observation is produced only when you specify the NORM option with METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING or when you specify the SNORM option with METHOD=SPACING.</td>
</tr>
<tr>
<td>NObsRead</td>
<td>number of physical records read</td>
</tr>
<tr>
<td>NObsUsed</td>
<td>number of physical records used in the analysis</td>
</tr>
<tr>
<td>NObsMiss</td>
<td>number of physical records containing missing values</td>
</tr>
</tbody>
</table>
SumFreqsRead  sum of the frequency variable (or the sum of NObsUsed ones when there is no frequency variable) for all observations read
SumFreqsUsed  sum of the frequency variable (or the sum of NObsUsed ones when there is no frequency variable) for all observations used in the analysis
SumWeightsRead  sum of the weight variable (or the sum of NObsUsed ones when there is no weight variable) for all observations read
SumWeightsUsed  sum of the weight variable (or the sum of NObsUsed ones when there is no weight variable) for all observations used in the analysis
Pn  percentiles of each variable, as specified by the PCTLPNTS= option. The argument n is any real number such that 0 ≤ n ≤ 100.

**Displayed Output**

If you specify the PSTAT option, PROC STDIZE displays the following statistics for each variable:

- the name of the variable, Name
- the location estimate, Location
- the scale estimate, Scale
- the norm estimate, Norm (when you specify the NORM option with METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING or when you specify the SNORM option with METHOD=SPACING)
- the total nonmissing positive frequencies, N

**ODS Table Names**

PROC STDIZE assigns a name to the single table it creates. You can use this name to reference the table when using the Output Delivery System (ODS) to select output or create an output data set. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**Table 66.3.** ODS Table Produced in PROC STDIZE

<table>
<thead>
<tr>

<td>Statistics</td>
<td>Location and Scale Measures</td>
<td>PSTAT</td>
</tr>
</tbody>
</table>
Example 66.1. Standardization of Variables in Cluster Analysis

To illustrate the effect of standardization in cluster analysis, this example uses the Fish data set described in the “Getting Started” section of Chapter 28, “The FASTCLUS Procedure.” The numbers are measurements taken on 159 fish caught from the same lake (Laengelmavesi) near Tampere in Finland; this data set is available from the Data Archive of the Journal of Statistics Education. The complete data set is displayed in Chapter 67, “The STEPDISC Procedure.”

The species (Bream, Parkki, Pike, Perch, Roach, Smelt, and Whitefish), weight, three different length measurements (measured from the nose of the fish to the beginning of its tail, the notch of its tail, and the end of its tail), height, and width of each fish are recorded. The height and width are recorded as percentages of the third length variable.

Several new variables are created in the Fish data set: Weight3, Height, Width, and logLengthRatio. The weight of a fish indicates its size—a heavier Tuna tends to be larger than a lighter Tuna. To get a one-dimensional measure of the size of a fish, take the cubic root of the weight (Weight3). The variables Height, Width, Length1, Length2, and Length3 are rescaled in order to adjust for dimensionality. The logLengthRatio variable measures the tail length.

Because the new variables Weight3–logLengthRatio depend on the variable Weight, observations with missing values for Weight are not added to the data set. Consequently, there are 157 observations in the SAS data set Fish.

Before you perform a cluster analysis on coordinate data, it is necessary to consider scaling or transforming the variables since variables with large variances tend to have a larger effect on the resulting clusters than those with small variances.

This example uses three different approaches to standardize or transform the data prior to the cluster analysis. The first approach uses several standardization methods provided in the STDIZE procedure. However, since standardization is not always appropriate prior to the clustering (refer to Milligan and Cooper, 1987, for a Monte Carlo study on various methods of variable standardization), the second approach performs the cluster analysis with no standardization. The third approach invokes the ACECLUS procedure to transform the data into a within-cluster covariance matrix.

The clustering is performed by the FASTCLUS procedure to find seven clusters. Note that the variables Length2 and Length3 are eliminated from this analysis since they both are significantly and highly correlated with the variable Length1. The correlation coefficients are 0.9958 and 0.9604, respectively. An output data set is created, and the FREQ procedure is invoked to compare the clusters with the species classification.

The DATA step is as follows:
proc format;
  value specfmt
  1='Bream'
  2='Roach'
  3='Whitefish'
  4='Parkki'
  5='Perch'
  6='Pike'
  7='Smelt';
data Fish (drop=HtPct WidthPct);
title 'Fish Measurement Data';
  input Species Weight Length1 Length2 Length3 HtPct WidthPct @@;
  if Weight <= 0 or Weight=. then delete;
  Weight3=Weight**(1/3);
  Height=HtPct*Length3/(Weight3*100);
  Width=WidthPct*Length3/(Weight3*100);
  Length1=Length1/Weight3;
  Length2=Length2/Weight3;
  Length3=Length3/Weight3;
  logLengthRatio=log(Length3/Length1);
  format Species specfmt.;
  symbol = put(Species, specfmt2.);
datalines;
1 242.0 23.2 25.4 30.0 38.4 13.4
1 290.0 24.0 26.3 31.2 40.0 13.8
1 340.0 23.9 26.5 31.1 39.8 15.1
1 363.0 26.3 29.0 33.5 38.0 13.3
... [155 more records]
;
run;

The following macro, Std, standardizes the Fish data. The macro reads a single argument, mtd, which selects the METHOD= specification to be used in PROC STDIZE.

/**--- macro for standardization ---*/
%macro Std(mtd);
  title2 "Data is standardized by PROC STDIZE withMETHOD= &mtd";
  proc stdize data=fish out=sdzout method=&mtd;
    var Length1 logLengthRatio Height Width Weight3;
  run;
%mend Std;

The following macro, FastFreq, includes a PROC FASTCLUS statement for performing cluster analysis and a PROC FREQ statement for cross-tabulating species with the cluster membership information that is derived from the previous PROC FASTCLUS statement. The macro reads a single argument, ds, which selects the input data set to be used in PROC FASTCLUS.
Example 66.1. Standardization of Variables in Cluster Analysis

/*--- macro for clustering and cross-tabulating ---*/
/*--- cluster membership with species ---*/
%macro FastFreq(ds);
   proc fastclus data=&ds out=clust maxclusters=7 maxiter=100 noprint;
      var Length1 logLengthRatio Height Width Weight3;
   run;

   proc freq data=clust;
      tables species*cluster;
   run;
%mend FastFreq;

The following analysis, (labeled ‘Approach 1’) includes 18 different methods of standardization followed by clustering. Since there is a large amount of output from this approach, only results from METHOD=STD, METHOD=RANGE, METHOD=AGK(.14), and METHOD=SPACING(.14) are shown. The following statements produce Output 66.1.1 through Output 66.1.4.

/*********************/

</tr>
</tbody>
</table>

In Output 66.1.1, the Bream species is classified as cluster 6 since all 34 Bream fish are categorized into cluster 6 with no misclassification. A similar pattern is seen with the Roach, Parkki, Pike, and Smelt species.

For the Whitefish species, two fish are categorized into cluster 2, one fish is categorized into cluster 4, and three fish are categorized into cluster 7. Because the majority of this species is categorized into cluster 7, it is recorded in Table 66.5 as being classified as cluster 7 with 3 misclassifications. A similar pattern is seen with the Perch species: it is classified as cluster 7 with 29 misclassifications.
In summary, when the standardization method is STD, seven species of fish are classified into only 5 clusters and the total number of misclassified observations is 33.

The result of this analysis demonstrates that when variables are standardized by the STDIZE procedure with methods including RANGE, MIDRANGE, MAXABS, AGK(.14), and SPACING(.14), the FASTCLUS procedure produces the correct number of clusters and less misclassification than it does when other standardization methods are used. The SPACING method attains the best result, probably because the variables Length1 and Height both exhibit marked groupings (bimodality) in their distributions.

Chapter 67
The STEPDISC Procedure

Overview

Given a classification variable and several quantitative variables, the STEPDISC procedure performs a stepwise discriminant analysis to select a subset of the quantitative variables for use in discriminating among the classes. The set of variables that make up each class is assumed to be multivariate normal with a common covariance matrix. The STEPDISC procedure can use forward selection, backward elimination, or stepwise selection (Klecka 1980). The STEPDISC procedure is a useful prelude to further analyses using the CANDISC procedure or the DISCRIM procedure.

With PROC STEPDISC, variables are chosen to enter or leave the model according to one of two criteria:

- the significance level of an $F$-test from an analysis of covariance, where the variables already chosen act as covariates and the variable under consideration is the dependent variable
- the squared partial correlation for predicting the variable under consideration from the CLASS variable, controlling for the effects of the variables already selected for the model

Forward selection begins with no variables in the model. At each step, PROC STEPDISC enters the variable that contributes most to the discriminatory power of the model as measured by Wilks’ Lambda, the likelihood ratio criterion. When none of the unselected variables meets the entry criterion, the forward selection process stops.

Backward elimination begins with all variables in the model except those that are linearly dependent on previous variables in the VAR statement. At each step, the variable that contributes least to the discriminatory power of the model as measured by Wilks’ Lambda is removed. When all remaining variables meet the criterion to stay in the model, the backward elimination process stops.

Stepwise selection begins, like forward selection, with no variables in the model. At each step, the model is examined. If the variable in the model that contributes least to the discriminatory power of the model as measured by Wilks’ lambda fails to meet the criterion to stay, then that variable is removed. Otherwise, the variable not in the model that contributes most to the discriminatory power of the model is entered. When all variables in the model meet the criterion to stay and none of the other variables meet the criterion to enter, the stepwise selection process stops. Stepwise selection is the default method of variable selection.
It is important to realize that, in the selection of variables for entry, only one variable can be entered into the model at each step. The selection process does not take into account the relationships between variables that have not yet been selected. Thus, some important variables could be excluded in the process. Also, Wilks’ Lambda may not be the best measure of discriminatory power for your application. However, if you use PROC STEPDISC carefully, in combination with your knowledge of the data and careful cross-validation, it can be a valuable aid in selecting variables for a discrimination model.

As with any stepwise procedure, it is important to remember that, when many significance tests are performed, each at a level of, for example, 5% (0.05), the overall probability of rejecting at least one true null hypothesis is much larger than 5%. If you want to prevent including any variables that do not contribute to the discriminatory power of the model in the population, you should specify a very small significance level. In most applications, all variables considered have some discriminatory power, however small. To choose the model that provides the best discrimination using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size.

Costanza and Afifi (1979) use Monte Carlo studies to compare alternative stopping rules that can be used with the forward selection method in the two-group multivariate normal classification problem. Five different numbers of variables, ranging from 10 to 30, are considered in the studies. The comparison is based on conditional and estimated unconditional probabilities of correct classification. They conclude that the use of a moderate significance level, in the range of 10 percent to 25 percent, often performs better than the use of a much larger or a much smaller significance level.

The significance level and the squared partial correlation criteria select variables in the same order, although they may select different numbers of variables. Increasing the sample size tends to increase the number of variables selected when using significance levels, but it has little effect on the number selected using squared partial correlations.

See Chapter 6, “Introduction to Discriminant Procedures,” for more information on discriminant analysis.

**Getting Started**

The data in this example are measurements on 159 fish caught in Finland’s lake Laengelmavesi; this data set is available from the Data Archive of the Journal of Statistics Education. For each of the seven species (bream, parkki, pike, perch, roach, smelt, and whitefish), the weight, length, height, and the width of each fish are tallied. Three different length measurements are recorded: from the nose of the fish to the beginning of its tail, from the nose to the notch of its tail, and from the nose to the end of its tail. The height and width are recorded as percentages of the third length variable. PROC STEPDISC will select a subset of the six quantitative variables that may be useful for differentiating between the fish species. This subset is used in conjunction with PROC CANDISC and PROC DISCRIM to develop discrimination models.
The following program creates the data set fish and uses PROC STEPDISC to select a subset of potential discriminator variables. By default, PROC STEPDISC uses stepwise selection on all numeric variables that are not listed in other statements, and the significance levels for a variable to enter the subset and to stay in the subset are set to 0.15.

```
PROC STEPDISC begins by displaying summary information about the analysis; see Figure 67.1. This information includes the number of observations with nonmissing values, the number of classes in the classification variable (specified by the CLASS statement), the number of quantitative variables under consideration, the significance criteria for variables to enter and to stay in the model, and the method of variable selection being used. The frequency of each class is also displayed.

Figure 67.3. Step 2: No Variable is Removed; Variable Length1 Added

The stepwise procedure terminates either when no variable can be removed and no variable can be entered or when the maximum number of steps as specified by the MAXSTEP= option has been attained. In this example at Step 7 no variables can be either removed or entered (Figure 67.4). Steps 3 through 6 are not displayed in this document.

No variables can be removed.
No further steps are possible.

Figure 67.4. Step 7: No Variables Entered or Removed

PROC STEPDISC ends by displaying a summary of the steps.

Figure 67.5. Step Summary

All the variables in the data set are found to have potential discriminatory power. These variables are used to develop discrimination models in both the CANDISC and DISCRIM procedure chapters.
Syntax

The following statements are available in PROC STEPDISC.

```
PROC STEPDISC < options > ;
   CLASS variable ;
   BY variables ;
   FREQ variable ;
   VAR variables ;
   WEIGHT variable ;
```

The BY, CLASS, FREQ, VAR, and WEIGHT statements are described after the PROC STEPDISC statement.

**PROC STEPDISC Statement**

```
PROC STEPDISC < options > ;
```

The PROC STEPDISC statement invokes the STEPDISC procedure. The PROC STEPDISC statement has the following options.

</tbody>
</table>

**ALL**
activates all of the display options.

**BCORR**
displays between-class correlations.

**BCOV**
displays between-class covariances. The between-class covariance matrix equals the between-class SSCP matrix divided by \( n(c - 1)/c \), where \( n \) is the number of observations and \( c \) is the number of classes. The between-class covariances should be interpreted in comparison with the total-sample and within-class covariances, not as formal estimates of population parameters.

**BSSCP**
displays the between-class SSCP matrix.

**DATA=SAS-data-set**
specifies the data set to be analyzed. The data set can be an ordinary SAS data set or one of several specially structured data sets created by statistical procedures available with SAS/STAT software. These specially structured data sets include TYPE=CORR, COV, CSSCP, and SSCP. If the DATA= option is omitted, the procedure uses the most recently created SAS data set.

**INCLUDE=n**
includes the first \( n \) variables in the VAR statement in every model. By default, INCLUDE=0.

**MAXSTEP=n**
specifies the maximum number of steps. By default, MAXSTEP= two times the number of variables in the VAR statement.

**METHOD=BACKWARD | BW**
**METHOD=FORWARD | FW**
**METHOD=STEPWISE | SW**
specifies the method used to select the variables in the model. The BACKWARD method specifies backward elimination, FORWARD specifies forward selection, and STEPWISE specifies stepwise selection. By default, METHOD=STEPWISE.
PCORR
displays pooled within-class correlations (partial correlations based on the pooled within-class covariances).

PCOV
displays pooled within-class covariances.

PR2ENTRY=\(p\)
PR2E=\(p\)
specifies the partial \(R^2\) for adding variables in the forward selection mode, where \(p \leq 1\).

PR2STAY=\(p\)
PR2S=\(p\)
specifies the partial \(R^2\) for retaining variables in the backward elimination mode, where \(p \leq 1\).

PSSCP
displays the pooled within-class corrected SSCP matrix.

SHORT
suppresses the displayed output from each step.

SIMPLE
displays simple descriptive statistics for the total sample and within each class.

SINGULAR=\(p\)
specifies the singularity criterion for entering variables, where \(0 < p < 1\). PROC STEPDISC precludes the entry of a variable if the squared multiple correlation of the variable with the variables already in the model exceeds \(1 - p\). With more than one variable already in the model, PROC STEPDISC also excludes a variable if it would cause any of the variables already in the model to have a squared multiple correlation (with the entering variable and the other variables in the model) exceeding \(1 - p\). By default, SINGULAR= 1E−8.

SLENTRY=\(p\)
SLE=\(p\)
specifies the significance level for adding variables in the forward selection mode, where \(0 \leq p \leq 1\). The default value is 0.15.

SLSTAY=\(p\)
SLS=\(p\)
specifies the significance level for retaining variables in the backward elimination mode, where \(0 \leq p \leq 1\). The default value is 0.15.

START=\(n\)
specifies that the first \(n\) variables in the VAR statement be used to begin the selection process. When you specify METHOD=FORWARD or METHOD=STEPWISE, the default value is 0; when you specify METHOD=BACKWARD, the default value is the number of variables in the VAR statement.
STDMEAN
displays total-sample and pooled within-class standardized class means.

STOP=n
specifies the number of variables in the final model. The STEPDISC procedure stops
the selection process when a model with n variables is found. This option applies
only when you specify METHOD=FORWARD or METHOD=BACKWARD. When
you specify METHOD=FORWARD, the default value is the number of variables in
the VAR statement; when you specify METHOD=BACKWARD, the default value is
0.

TCORR
displays total-sample correlations.

TCOV
displays total-sample covariances.

TSSCP
displays the total-sample corrected SSCP matrix.

WCORR
displays within-class correlations for each class level.

WCOV
displays within-class covariances for each class level.

WSSCP
displays the within-class corrected SSCP matrix for each class level.

**BY Statement**

```
BY variables;
```

You can specify a BY statement with PROC STEPDISC to obtain separate analy-
ses on observations in groups defined by the BY variables. When a BY statement
appears, the procedure expects the input data set to be sorted in order of the BY
variables.

If your input data set is not sorted in ascending order, use one of the following alter-
natives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY
  statement for the STEPDISC procedure. The NOTSORTED option does not
  mean that the data are unsorted but rather that the data are arranged in groups
  (according to values of the BY variables) and that these groups are not neces-
  sarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base
  SAS software).

For more information on the BY statement, refer to the discussion in *SAS Language
Reference: Concepts*. For more information on the DATASETS procedure, refer to
the discussion in the *SAS Procedures Guide*. 
CLASS Statement

CLASS variable;

The values of the CLASS variable define the groups for analysis. Class levels are determined by the formatted values of the CLASS variable. The CLASS variable can be numeric or character. A CLASS statement is required.

FREQ Statement

FREQ variable;

If a variable in the data set represents the frequency of occurrence for the other values in the observation, include the name of the variable in a FREQ statement. The procedure then treats the data set as if each observation appears \( n \) times, where \( n \) is the value of the FREQ variable for the observation. The total number of observations is considered to be equal to the sum of the FREQ variable when the procedure determines degrees of freedom for significance probabilities.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, the value is truncated to an integer.

VAR Statement

VAR variables;

The VAR statement specifies the quantitative variables eligible for selection. The default is all numeric variables not listed in other statements.

WEIGHT Statement

WEIGHT variable;

To use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the WEIGHT variable are proportional to the reciprocals of the variances. If the value of the WEIGHT variable is missing or is less than zero, then a value of zero for the weight is assumed.

The WEIGHT and FREQ statements have a similar effect except that the WEIGHT statement does not alter the degrees of freedom.
Details

Missing Values

Observations containing missing values are omitted from the analysis.

Input Data Sets

The input data set can be an ordinary SAS data set or one of several specially structured data sets created by statistical procedures available with SAS/STAT software. For more information on these data sets, see Appendix A, “Special SAS Data Sets.” The BY variable in these data sets becomes the CLASS variable in PROC STEPDISC. These specially structured data sets include

- TYPE=CORR data sets created by PROC CORR using a BY statement
- TYPE=COV data sets created by PROC PRINCOMP using both the COV option and a BY statement
- TYPE=CSSCP data sets created by PROC CORR using the CSSCP option and a BY statement, where the OUT= data set is assigned TYPE=CSSCP with the TYPE= data set option
- TYPE=SSCP data sets created by PROC REG using both the OUTSSCP= option and a BY statement

When the input data set is TYPE=CORR, TYPE=COV, or TYPE=CSSCP, the STEPDISC procedure reads the number of observations for each class from the observations with _TYPE_ = ’N’ and the variable means in each class from the observations with _TYPE_ = ’MEAN’. The procedure then reads the within-class correlations from the observations with _TYPE_ = ’CORR’, the standard deviations from the observations with _TYPE_ = ’STD’ (data set TYPE=CORR), the within-class covariances from the observations with _TYPE_ = ’COV’ (data set TYPE=COV), or the within-class corrected sums of squares and crossproducts from the observations with _TYPE_ = ’CSSCP’ (data set TYPE=CSSCP).

When the input data set is TYPE=SSCP, the STEPDISC procedure reads the number of observations for each class from the observations with _TYPE_ = ’N’, the sum of weights of observations from the variable INTERCEPT in observations with _TYPE_ = ’SSCP’ and _NAME_ = ’INTERCEPT’, the variable sums
from the variable=variablenames in observations with _TYPE_='SSCP' and _NAME_='INTERCEPT', and the uncorrected sums of squares and crossproducts from the variable=variablenames in observations with _TYPE_='SSCP' and _NAME_=variablenames.

**Computational Resources**

In the following discussion, let

\[ n = \text{number of observations} \]
\[ c = \text{number of class levels} \]
\[ v = \text{number of variables in the VAR list} \]
\[ l = \text{length of the CLASS variable} \]
\[ t = v + c - 1. \]

**Memory Requirements**

The amount of memory in bytes for temporary storage needed to process the data is

\[ c(4v^2 + 28v + 3l + 4c + 72) + 16v^2 + 92v + 4t^2 + 20t + 4l \]

Additional temporary storage of 72 bytes at each step is also required to store the results.

**Time Requirements**

The following factors determine the time requirements of a stepwise discriminant analysis.

- The time needed for reading the data and computing covariance matrices is proportional to \( nv^2 \). The STEPDISC procedure must also look up each class level in the list. This is faster if the data are sorted by the CLASS variable. The time for looking up class levels is proportional to a value ranging from \( n \) to \( n \ln(c) \).
- The time needed for stepwise discriminant analysis is proportional to the number of steps required to select the set of variables in the discrimination model. The number of steps required depends on the data set itself and the selection method and criterion used in the procedure. Each forward or backward step takes time proportional to \( (v + c)^2 \).
Displayed Output

The STEPDISC procedure displays the following output:

- Class Level Information, including the values of the classification variable, the Frequency of each value, the Weight of each value, and the Proportion of each value in the total sample

Optional output includes

- Within-Class SSCP Matrices for each group
- Pooled Within-Class SSCP Matrix
- Between-Class SSCP Matrix
- Total-Sample SSCP Matrix
- Within-Class Covariance Matrices for each group
- Pooled Within-Class Covariance Matrix
- Between-Class Covariance Matrix, equal to the between-class SSCP matrix divided by \( n(c - 1)/c \), where \( n \) is the number of observations and \( c \) is the number of classes
- Total-Sample Covariance Matrix
- Within-Class Correlation Coefficients and \( Pr > |r| \) to test the hypothesis that the within-class population correlation coefficients are zero
- Pooled Within-Class Correlation Coefficients and \( Pr > |r| \) to test the hypothesis that the partial population correlation coefficients are zero
- Between-Class Correlation Coefficients and \( Pr > |r| \) to test the hypothesis that the between-class population correlation coefficients are zero
- Total-Sample Correlation Coefficients and \( Pr > |r| \) to test the hypothesis that the total population correlation coefficients are zero
- descriptive Simple Statistics including \( N \) (the number of observations), Sum, Mean, Variance, and Standard Deviation for the total sample and within each class
- Total-Sample Standardized Class Means, obtained by subtracting the grand mean from each class mean and dividing by the total-sample standard deviation
- Pooled Within-Class Standardized Class Means, obtained by subtracting the grand mean from each class mean and dividing by the pooled within-class standard deviation

At each step, the following statistics are displayed:

- for each variable considered for entry or removal: Partial R-Square, the squared (partial) correlation, the \( F \) statistic, and \( Pr > F \), the probability level, from a one-way analysis of covariance
the minimum Tolerance for entering each variable. A variable is entered only if its tolerance and the tolerances for all variables already in the model are greater than the value specified in the SINGULAR= option. The tolerance for the entering variable is $1 - R^2$ from regressing the entering variable on the other variables already in the model. The tolerance for a variable already in the model is $1 - R^2$ from regressing that variable on the entering variable and the other variables already in the model. With $m$ variables already in the model, for each entering variable, $m + 1$ multiple regressions are performed using the entering variable and each of the $m$ variables already in the model as a dependent variable. These $m + 1$ tolerances are computed for each entering variable, and the minimum tolerance is displayed for each.

The tolerance is computed using the total-sample correlation matrix. It is customary to compute tolerance using the pooled within-class correlation matrix (Jennrich 1977), but it is possible for a variable with excellent discriminatory power to have a high total-sample tolerance and a low pooled within-class tolerance. For example, PROC STEPDISC enters a variable that yields perfect discrimination (that is, produces a canonical correlation of one), but a program using pooled within-class tolerance does not.

- the variable Label, if any
- the name of the variable chosen
- the variables already selected or removed
- Wilks’ Lambda and the associated $F$ approximation with degrees of freedom and $Pr < F$, the associated probability level after the selected variable has been entered or removed. Wilks’ lambda is the likelihood ratio statistic for testing the hypothesis that the means of the classes on the selected variables are equal in the population (see the “Multivariate Tests” section in Chapter 2, “Introduction to Regression Procedures.”) Lambda is close to zero if any two groups are well separated.
- Pillai’s Trace and the associated $F$ approximation with degrees of freedom and $Pr > F$, the associated probability level after the selected variable has been entered or removed. Pillai’s trace is a multivariate statistic for testing the hypothesis that the means of the classes on the selected variables are equal in the population (see the “Multivariate Tests” section in Chapter 2).
- Average Squared Canonical Correlation (ASCC). The ASCC is Pillai’s trace divided by the number of groups minus 1. The ASCC is close to 1 if all groups are well separated and if all or most directions in the discriminant space show good separation for at least two groups.
- Summary to give statistics associated with the variable chosen at each step. The summary includes the following:
  - Step number
  - Variable Entered or Removed
  - Number In, the number of variables in the model
  - Partial R-Square
  - the $F$ Value for entering or removing the variable
– Pr > $F$, the probability level for the $F$ statistic
– Wilks’ Lambda
– Pr < Lambda based on the $F$ approximation to Wilks’ Lambda
– Average Squared Canonical Correlation
– Pr > ASCC based on the $F$ approximation to Pillai’s trace
– the variable Label, if any

**ODS Table Names**

PROC STEPDISC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Example 67.1. Performing a Stepwise Discriminant Analysis

The iris data published by Fisher (1936) have been widely used for examples in discriminant analysis and cluster analysis. The sepal length, sepal width, petal length, and petal width are measured in millimeters on fifty iris specimens from each of three species: *Iris setosa*, *I. versicolor*, and *I. virginica*.

```plaintext

```
A stepwise discriminant analysis is performed using stepwise selection.

In the PROC STEPDISC statement, the BSSCP and TSSCP options display the between-class SSCP matrix and the total-sample corrected SSCP matrix. By default, the significance level of an $F$ test from an analysis of covariance is used as the selection criterion. The variable under consideration is the dependent variable, and the variables already chosen act as covariates. The following SAS statements produce Output 67.1.1 through Output 67.1.8:

```sas
proc stepdisc data=iris bsscp tsscp;
  class Species;
  var SepalLength SepalWidth PetalLength PetalWidth;
run;
```

Output 67.1.1.  Iris Data: Summary Information

Fisher (1936) Iris Data

In Step 2, with variable PetalLength already in the model, PetalLength is tested for removal before selecting a new variable for entry. Since PetalLength meets the criterion to stay, it is used as a covariate in the analysis of covariance for variable selection. Variable SepalWidth is selected because its $F$ statistic, 43.035, is the largest among all variables not in the model and its associated tolerance, 0.8164, meets the criterion to enter. The process is repeated in Steps 3 and 4. Variable PetalWidth is entered in Step 3, and variable SepalLength is entered in Step 4.

Chapter 68
The SURVEYFREQ Procedure

Overview

The SURVEYFREQ procedure produces one-way to \( n \)-way frequency and crosstabulation tables from sample survey data. These tables include estimates of population totals and proportions, and the corresponding standard errors. PROC SURVEYFREQ computes the variance estimates based on the sample design used to obtain the survey data. The design can be a complex multistage survey design with stratification, clustering, and unequal weighting. PROC SURVEYFREQ also provides design-based tests of independence and association between variables.

PROC SURVEYFREQ uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method is appropriate for all designs where the first-stage sample is selected with replacement, or where the first-stage sampling fraction is small, as it often is in practice. The Taylor expansion method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters or primary sampling units (PSUs) in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure combines stratum variance estimates to compute the overall variance estimate.

Getting Started

The following example shows how you can use PROC SURVEYFREQ to analyze sample survey data. The example uses data from a customer satisfaction survey for a student information system (SIS), a software product that provides modules for student registration, class scheduling, attendance, grade reporting, and other functions.

The software company conducted a survey of school personnel who use the SIS. A probability sample of SIS users was selected from the study population, which included SIS users at middle schools and high schools in the three-state area of Georgia, South Carolina, and North Carolina. The sample design for this survey was a two-stage stratified design. A first-stage sample of schools was selected from the list of schools using the SIS in the three-state area. The list of schools, or the first-stage sampling frame, was stratified by state and by customer status (whether the school was a new user of the system, or a renewal user). Within the first-stage strata, schools were selected with probability proportional to size and with replacement, where the size measure was school enrollment. From each sample school, five staff members were randomly selected to complete the SIS satisfaction questionnaire. These staff members included three teachers, and two administrators or guidance staff members.
The SAS data set SIS_Survey contains the survey results, as well as the sample design information needed to analyze the data. This data set includes an observation for each school staff member responding to the survey. The variable Response contains the staff member’s response on overall satisfaction with the system.

The variable State contains the school’s state, and the variable NewUser contains the school’s customer status (‘New Customer’ or ‘Renewal Customer’). These two variables determine the first stage strata from which schools were selected. The variable School contains the school identification code and identifies the first-stage sampling units, or clusters. The variable SamplingWeight contains the overall sampling weight for each respondent. Overall sampling weights were computed from the selection probabilities at each stage of sampling and were adjusted for nonresponse.

Other variables in the data set SIS_Survey include SchoolType and Department. The variable SchoolType identifies the school as a high school or a middle school. The variable Department identifies the staff member as a teacher, or an administrator or guidance department member.

The following PROC SURVEYFREQ statements request a one-way table for the variable Response.

```plaintext
   title 'School Information System Survey';
   proc surveyfreq data=SIS_Survey;
      tables Response;
      strata State NewUser;
      cluster School;
      weight SamplingWeight;
   run;
```

The PROC SURVEYFREQ statement invokes the procedure and identifies the input data set to be analyzed. The TABLES statement requests a one-way table for the variable Response. The table request syntax for PROC SURVEYFREQ is very similar to the PROC FREQ table request syntax. This example shows a request for a single one-way table, but you can also request two-way tables or multiway tables. As in PROC FREQ, you can request more than one table in the same TABLES statement, and you can use multiple TABLES statements in the same invocation of PROC SURVEYFREQ.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information to the procedure, so that the analysis is done according to the sample design used for the survey, and the estimates apply to the study population. The STRATA statement names the variables State and NewUser, which identify the first-stage strata. Note that the design for this example also includes stratification at the second stage of selection (by type of school personnel), but you specify only the first-stage strata for PROC SURVEYFREQ. The CLUSTER statement identifies School as the cluster or first-stage sampling unit. The WEIGHT statement names the sampling weight variable.
Figure 68.1 and Figure 68.2 display the output produced by PROC SURVEYFREQ, which includes the Data Summary table and the one-way Table of Response. The Data Summary table is produced by default unless you specify the NOSUMMARY option. This table shows there are 6 strata, 370 clusters or schools, and 1850 observations or respondents in the SIS_Survey data set. The sum of the sampling weights is approximately 39,000, which estimates the total number of school personnel using the SIS in the study area.

Figure 68.1. SIS_Survey Data Summary

Figure 68.2 displays the one-way table for Response, which provides estimates of the population total (weighted frequency) and the population percentage for each category, or level, of Response. The response level 'Very Unsatisfied' has a frequency of 304, which means that 304 sample respondents fall into this category. It is estimated that 17.17% of all school personnel in the study population fall into this category, and the standard error of this estimate is 1.29%. Note that the estimates apply to the population of all SIS users in the study area, as opposed to describing only the sample of 1850 respondents. The estimate of the total number of school personnel 'Very Unsatisfied' is 6,678, with a standard deviation of 502. The standard errors computed by PROC SURVEYFREQ are based on the multistage stratified design used for the survey. This differs from some of the traditional analysis procedures, which assume the design is simple random sampling from an infinite population.

<table>
<thead>
<tr>
<th>School Information System Survey</th>

</tr>
</tbody>
</table>

Figure 68.2. One-Way Table of Response
The following PROC SURVEYFREQ statements request confidence limits for the percentage estimates and a chi-square goodness-of-fit test for the one-way table of Response.

```
proc surveyfreq data=SIS_Survey nosummary;
tables Response / cl nowt chisq;
Strata State NewUser;
ccluster School;
weight SamplingWeight;
run;
```

The NOSUMMARY option in the PROC statement suppresses the Data Summary table. In the TABLES statement, the CL option requests confidence limits for the percentages in the one-way table. The NOWT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square goodness-of-fit test.

Figure 68.3 shows the one-way table of Response, which includes confidence limits for the percentages. The 95% confidence limits for the percentage of users that are 'Very Unsatisfied' are 14.64% and 19.70%. To change the $\alpha$ level of the confidence limits, which equals 5% by default, you can use the ALPHA= option. As for the other estimates and standard errors produced by PROC SURVEYFREQ, these confidence limit computations take into account the complex sample design used for the survey, and the results apply to the entire study population.

**Figure 68.3.** Confidence Limits for Response Percentages
Figure 68.4 shows the chi-square goodness-of-fit results for the table of Response. The null hypothesis for this test is equal proportions for the levels of the one-way table. (To test a null hypothesis of specified proportions instead of equal proportions, you can use the TESTP= option to specify null hypothesis proportions.)

The chi-square test invoked by the CHISQ option is the Rao-Scott design-adjusted chi-square test, which takes the survey design into account and provides inferences for the entire study population. To produce the Rao-Scott chi-square statistic, PROC SURVEYFREQ first computes the usual Pearson chi-square statistic based on the weighted frequencies, and then adjusts this value with a design correction. An $F$ approximation is also provided. For the table of Response, the $F$ value is 632.85 with a $p$-value < .0001, which leads to rejection of the null hypothesis of equal proportions for all response levels.

```

**Figure 68.4.** Chi-Square Goodness-of-Fit Test for Response

Continuing to analyze the SIS_Survey data, the following PROC SURVEYFREQ statements request a two-way table for the variables SchoolType by Response.

```
proc surveyfreq data=SIS_Survey nosummary;
 tables SchoolType * Response;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;
```

The STRATA, CLUSTER and WEIGHT statements do not change from the one-way table example, since the survey design and the input data set are the same. These SURVEYFREQ statements request a different table, but specify the same sample design information.
Figure 68.5 shows the two-way table produced. The first variable named in the two-way table request, `SchoolType`, is referred to as the *row variable*, and the second variable named, `Response`, is referred to as the *column variable*. Two-way tables display all column variable levels for each row variable level. So this two-way table lists all levels of the column variable `Response` for each level of the row variable `SchoolType`, 'Middle School' and 'High School'. Also `SchoolType = 'Total'` shows the distribution of `Response` overall for both types of schools. And `Response = 'Total'` provides totals over all levels of response, for each type of school and overall. To suppress these totals, you can use the NOTOTAL option.

By default, without any other TABLES statement options, a two-way table displays the frequency, weighted frequency and its standard deviation, and percentage and its standard error for each table cell, or combination of row and column variable levels. But there are several options available to customize your table display by adding more information or suppressing some of the default information.

*Figure 68.5. Two-Way Table of `SchoolType` by `Response*
The following PROC SURVEYFREQ statements request a two-way table of `SchoolType` by `Response` with row percentages, and also request a chi-square test for association between the two variables.

```
proc surveyfreq data=SIS_Survey nosummary;
tables SchoolType * Response / row nowt chisq;
strata State NewUser;
cluster School;
weight SamplingWeight;
run;
```

The ROW option in the TABLES statement requests row percentages, which display the distribution of `Response` as a percentage of each level of the row variable `SchoolType`. The NOWT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square test of association between `SchoolType` and `Response`.

Figure 68.6 displays the two-way table produced. For middle schools, it is estimated that 25.79% of school personnel are satisfied with the school information system, and 12.39% are very satisfied. For high schools, these estimates are 22.67% and 7.61%, respectively.

![Figure 68.6. Two-Way Table with Row Percentages](image-url)
Figure 68.7 displays the chi-square test results. The Rao-Scott chi-square statistic equals 190.19, and the corresponding $F$ value is 47.55 with a $p$-value < .0001. This indicates a significant association between school type (middle school or high school) and satisfaction with the student information system.

**Figure 68.7.** Chi-Square Test of No Association

**Syntax**

The following statements are available in PROC SURVEYFREQ.

```
PROC SURVEYFREQ < options > ;
   BY variables ;
   CLUSTER variables ;
   STRATA variables < / option > ;
   TABLES requests < / options > ;
   WEIGHT variable ;
```

The PROC SURVEYFREQ statement invokes the procedure, identifies the data set to be analyzed, and provides sample design information. The PROC SURVEYFREQ statement is required.

The TABLES statement specifies frequency or crosstabulation tables and requests tests and statistics for those tables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The WEIGHT statement names the sampling weight variable. You can use a BY statement with PROC SURVEYFREQ to obtain separate analyses for groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYFREQ statement and the WEIGHT statement, which can appear only once.
The rest of this section gives detailed syntax information for the BY, CLUSTER, STRATA, TABLES, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYFREQ statement.

PROC SURVEYFREQ Statement

PROC SURVEYFREQ < options > ;

The PROC SURVEYFREQ statement invokes the procedure. In this statement, you identify the data set to be analyzed and specify sample design information. The DATA= option names the input data set to be analyzed. If your analysis includes a finite population correction factor, you can input either the sampling rate or the population total using the RATE= or TOTAL= option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set containing the stratification variables.

You can specify the following options in the PROC SURVEYFREQ statement:

- **DATA=SAS-data-set**
  names the SAS data set to be analyzed by PROC SURVEYFREQ. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

- **MISSING**
  requests that the procedure treat missing values as a valid category for all categorical variables, which include TABLES variables, STRATA variables, and CLUSTER variables. For more information, see the section “Missing Values” on page 4205.

- **NOSUMMARY**
  suppresses the display of the Data Summary table, which PROC SURVEYFREQ produces by default. For a description of this table, see the section “Data and Sample Design Summary Table” on page 4225.

- **ORDER=DATA | FORMATTED | FREQ | INTERNAL**
  specifies the order in which the values of the frequency and crosstabulation table variables are to be reported. The following table shows how PROC SURVEYFREQ interprets values of the ORDER= option:

<table>
<thead>
<tr>
<th>ORDER= Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>orders values according to their order in the input data set.</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>orders values by their formatted values. This order is operating-environment dependent. By default, the order is ascending.</td>
</tr>
<tr>
<td>FREQ</td>
<td>orders values by descending frequency count. The frequency count of a variable value is its (nonweighted) frequency of occurrence or sample size, and not its weighted frequency.</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>orders values by their unformatted values, which yields the same order that the SORT procedure does. This order is operating-environment dependent.</td>
</tr>
</tbody>
</table>

By default, ORDER=INTERNAL.
PAGE
displays only one table per page. Otherwise, PROC SURVEYFREQ displays multiple tables per page as space permits.

RATE=value | SAS-data-set
R=value | SAS-data-set
specifies the sampling rate as a nonnegative value, or identifies an input data set that gives the stratum sampling rates in a variable named _RATE_. The procedure uses this information to compute a finite population correction for variance estimation. If your sample design has multiple stages, you should specify the first-stage sampling rate, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative value for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “Population Totals and Sampling Rates” on page 4204 for more details.

The sampling rate value must be a nonnegative number. You can specify value as a number between 0 and 1. Or you can specify value in percentage form as a number between 1 and 100, and PROC SURVEYFREQ will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

TOTAL=value | SAS-data-set
N=value | SAS-data-set
specifies the total number of primary sampling units (PSUs) in the study population as a positive value, or identifies an input data set that gives the stratum population totals in a variable named _TOTAL_. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive value for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “Population Totals and Sampling Rates” on page 4204 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.
BY Statement

BY variables ;

You can specify a BY statement with PROC SURVEYFREQ to obtain separate analyses on observations in groups defined by the BY variables. The variables are one or more variables in the input data set.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, the difference being that in domain analysis the total number of units in the subpopulation is not known with certainty. You should include the domain variable(s) in your TABLES request to obtain domain analysis. See the section “Domain Analysis” on page 4205 for more details.

If you specify more than one BY statement, the procedure uses only the last BY statement and ignores any previous BY statements.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the FREQ procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

CLUSTER Statement

CLUSTER variables ;

The CLUSTER statement names variables that identify the first-stage clusters, or PSUs, in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters or primary sampling units (PSUs) in the CLUSTER statement. See the section “Specifying the Sample Design” on page 4203 for more information.

The CLUSTER variables are one or more variables in the DATA= input data set. These variables can either be character or numeric, but the procedure treats them as categorical variables. The formatted values of the CLUSTER variables determine the
CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

You can use multiple CLUSTER statements to specify CLUSTER variables. The procedure uses variables from all CLUSTER statements to create clusters.

**STRATA Statement**

```
STRATA variables < / option > ;
```

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specifying the Sample Design” on page 4203 for more information.

The STRATA variables are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical. The formatted values of the STRATA variables determine the STRATA variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

You can specify the following option in the STRATA statement after a slash (/):

**LIST**

displays a “Stratum Information” table, which lists all strata together with the corresponding values of the STRATA variables. This table provides the number of observations and number of clusters for each stratum, as well as the sampling fraction if you specify the RATE= or the TOTAL= option. See the section “Stratum Information Table” on page 4225 for more information.

**TABLES Statement**

```
TABLES requests < / options > ;
```

The TABLES statement requests one-way to \( n \)-way frequency and crosstabulation tables and statistics for those tables.

If you omit the TABLES statement, PROC SURVEYFREQ generates one-way frequency tables for all data set variables that are not listed in the other statements.

The following argument is required in the TABLES statement.

**requests**

specify the frequency and crosstabulation tables to produce. A request is composed of one variable name or several variable names separated by asterisks. To request a one-way frequency table, use a single variable. To request a two-way crosstabulation table, use an asterisk between two variables. To request a multiway table (an \( n \)-way
table, where \( n > 2 \), separate the desired variables with asterisks. The unique values of these variables form the rows, columns, and layers of the table.

For two-way tables to multiway tables, the values of the last variable form the crosstabulation table columns, while the values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate crosstabulation table for each layer. For example, a specification of \( A*B*C*D \) in a TABLES statement produces \( k \) tables, where \( k \) is the number of different combinations of levels for \( A \) and \( B \). Each table lists the levels for \( D \) (columns) within each level of \( C \) (rows).

You can use multiple TABLES statements in the PROC SURVEYFREQ step. You can also specify any number of table requests in a single TABLES statement. To specify multiple table requests quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. For example, the following statements illustrate grouping syntax:

<table>
<thead>
<tr>
<th>Request</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables ( A*(B \ C) )</td>
<td>tables ( A<em>B \ A</em>C )</td>
</tr>
<tr>
<td>tables ( (A \ B)*(C \ D) )</td>
<td>tables ( A<em>C \ B</em>C \ A<em>D \ B</em>D )</td>
</tr>
<tr>
<td>tables ( (A \ B \ C)*D )</td>
<td>tables ( A<em>D \ B</em>D \ C*D )</td>
</tr>
<tr>
<td>tables ( A -- C )</td>
<td>tables ( A \ B \ C )</td>
</tr>
<tr>
<td>tables ( (A -- C)*D )</td>
<td>tables ( A<em>D \ B</em>D \ C*D )</td>
</tr>
</tbody>
</table>

The TABLES statement variables are one or more variables from the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. PROC SURVEYFREQ uses the formatted values of the TABLES variable to determine the categorical variable levels. So if you assign a format to a variable with a FORMAT statement, PROC SURVEYFREQ formats the values before dividing observations into the levels of a frequency or crosstabulation table. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

The frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values unless you change the order with the ORDER= option. To list the values in ascending order by formatted value, use ORDER=FORMATTED in the PROC SURVEYFREQ statement.

**Without Options**

If you request a frequency or crosstabulation table without specifying options, PROC SURVEYFREQ produces the following for each table level or cell:

- frequency (sample size)
- weighted frequency (estimated total)
- standard error of weighted frequency
- percentage (estimated proportion)
- standard error of percentage
The table displays weighted frequencies if your analysis includes a WEIGHT statement, or if you specify the WTFFREQ option in the TABLES statement. The table also displays the number of observations with missing values. See the section “One-Way Frequency Tables” on page 4226 and the section “Crosstabulation Tables” on page 4227 for more information.

**Options**

The following table lists the options available with the TABLES statement. Descriptions follow in alphabetical order.

### Table 68.2. TABLES Statement Options

</tr>
</tbody>
</table>
You can specify the following options in a TABLES statement:

**ALPHA=α**
sets the level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default is 0.05. A confidence level of α produces \(100(1 - \alpha)\)% confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

You request confidence limits for percentages with the **CL** option, and you request confidence limits for weighted frequencies with the **CLWT** option. See the section “Confidence Limits” on page 4213 for more information.

**CHISQ**
requests the Rao-Scott chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies. See the section “Rao-Scott Chi-Square Test” on page 4216 for more information.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the **TESTP=** option.

The CHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the **CHISQ1** option.

**CHISQ1**
requests the Rao-Scott modified chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section “Rao-Scott Chi-Square Test” on page 4216 for more information. To compute the design effect correction from proportion estimates instead of null proportions, specify the CHISQ option.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the **TESTP=** option.

**CL**
requests confidence limits for the percentages, or proportion estimates, in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits. See the section “Confidence Limits” on page 4213 for more information.

**CLWT**
requests confidence limits for the weighted frequencies, or estimated totals, in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits. See the section “Confidence Limits” on page 4213 for more information.
COL

Displays the column percentage, or estimated proportion of the column total, for each cell in a two-way table. The COL option also displays the standard errors of the column percentages. See the section “Row and Column Proportions” on page 4212 for more information. This option has no effect for one-way tables.

CV

Displays the coefficient of variation for each percentage, or proportion estimate, in the crosstabulation table. See the section “Coefficient of Variation” on page 4214 for more information.

CVWT

Displays the coefficient of variation for each weighted frequency, or estimated total, in the crosstabulation table. See the section “Coefficient of Variation” on page 4214 for more information.

DDF=\text{df}

Specifies the denominator degrees of freedom for the $F$-statistics used in the Wald chi-square tests. By default, the denominator degrees of freedom is the number of clusters minus the number of strata. See the section “Wald Chi-Square Test” on page 4221 and the section “Wald Log-Linear Chi-Square Test” on page 4223 for more information. You request the Wald chi-square test with the WCHISQ option, and you request the Wald log-linear chi-square test with the WLLCHISQ option.

DEFF

Displays the design effect for each overall proportion estimate in the crosstabulation table. See the section “Design Effect” on page 4215 for more information.

EXPECTED

Displays expected weighted frequencies for the table cells in a two-way table. The expected frequencies are computed under the null hypothesis that the row and column variables are independent. See the section “Expected Weighted Frequency” on page 4215 for more information. This option has no effect for one-way tables.

LRCHISQ

Requests the Rao-Scott likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies. See the section “Rao-Scott Likelihood Ratio Chi-Square Test” on page 4219 for more information.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

The LRCHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the LRCHISQ1 option.

LRCHISQ1

Requests the Rao-Scott modified likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section “Rao-Scott Likelihood Ratio Chi-Square Test” on page
4219 for more information. To compute the design effect correction from proportion estimates instead of null proportions, specify the LRCHISQ option.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the TESTP= option.

**NOFREQ**

suppresses the display of cell frequencies in the crosstabulation table. The NOFREQ option also suppresses the display of row, column, and overall table frequencies.

**NOPERCENT**

suppresses the display of cell percentages in the crosstabulation table. The NOPERCENT option also suppresses the display of standard errors of the percentages.

**NOPRINT**

suppresses the display of frequency and crosstabulation tables but displays all requested statistical tests. Note that this option disables the Output Delivery System (ODS) for the suppressed tables. For more information, see Chapter 14, “Using the Output Delivery System.”

**NOSPARSE**

suppresses the display of variable levels with zero frequency in two-way tables. By default, the procedure displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row variable levels with zero frequency for the layer. Also by default, the procedure displays all variable levels that occur in the input data set, including those levels with no observations actually used in the analysis due to missing or nonpositive weights or missing values. See the section “Missing Values” on page 4205 for details.

**NOSTD**

suppresses the display of all standard errors in the crosstabulation table.

**NOTOTAL**

suppresses the display of row totals, column totals, and overall totals in the crosstabulation table.

**NOWT**

suppresses the display of weighted frequencies in the crosstabulation table. The NOWT option also suppresses the display of standard errors of the weighted frequencies.

**ROW**

displays the row percentage, or estimated proportion of the row total, for each cell in a two-way table. The ROW option also displays the standard errors of the row percentages. See the section “Row and Column Proportions” on page 4212 for more information. This option has no effect for one-way tables.
TESTP=(values)
specifies null hypothesis proportions, or test percentages, for one-way chi-square tests. You can separate values with blanks or commas. Specify values in probability form as numbers between 0 and 1, where the proportions sum to 1. Or specify values in percentage form as numbers between 0 and 100, where the percentages sum to 100. PROC SURVEYFREQ treats the value 1 as the percentage form 1%. The number of TESTP= values must equal the number of variable levels in the one-way table. List these values in the order in which the corresponding variable levels appear in the output.

When you specify the TESTP= option, PROC SURVEYFREQ displays the specified test percentages in the one-way frequency table. The TESTP= option has no effect for two-way tables.

PROC SURVEYFREQ uses the TESTP= values for all one-way chi-square tests you request in the TABLES statement. The available one-way chi-square tests include the Rao-Scott (Pearson) chi-square test and the Rao-Scott likelihood ratio chi-square test and their modified versions, requested by options CHISQ, CHISQ1, LRCHISQ, and LRCHISQ1. See the section “Rao-Scott Chi-Square Test” on page 4216 and the section “Rao-Scott Likelihood Ratio Chi-Square Test” on page 4219 for more details.

VAR
  displays the variance estimate for each percentage in the crosstabulation table. See the section “Proportions” on page 4210 for details.

VARWT
  displays the variance estimate for each weighted frequency, or estimated total, in the crosstabulation table. See the section “Totals” on page 4209 for details.

WCHISQ
  requests the Wald chi-square test. See the section “Wald Chi-Square Test” on page 4221 for more information. By default, the denominator degrees of freedom for the Wald test F-statistic is the number of clusters minus the number of strata. Alternatively, you can specify the denominator degrees of freedom with the DDF= option.

WLLCHISQ
  requests the Wald log-linear chi-square test. See the section “Wald Log-Linear Chi-Square Test” on page 4223 for more information. By default, the denominator degrees of freedom for the Wald test F-statistic is the number of clusters minus the number of strata. Alternatively, you can specify the denominator degrees of freedom with the DDF= option.

WTFREQ
  displays the weighted frequencies and their standard errors when you do not specify a WEIGHT statement. PROC SURVEYFREQ displays the weighted frequencies by default when the analysis includes a WEIGHT statement. Without a WEIGHT statement, PROC SURVEYFREQ assigns all observations a weight of 1.
**WEIGHT Statement**

```plaintext
WEIGHT variable ;
```

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYFREQ assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 4205 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

**Details**

**Specifying the Sample Design**

PROC SURVEYFREQ produces tables and statistics based on the sample design used to obtain the survey data. The procedure uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. See the section “Statistical Computations” on page 4206 for details. This method is appropriate for all designs where the first-stage sample is selected with replacement, or where the first-stage sampling fraction is small, as it often is in practice.

PROC SURVEYFREQ can be used for single-stage designs or for multistage designs, with or without stratification, and with or without unequal weighting. You provide sample design information with the STRATA, CLUSTER, and WEIGHT statements, and with the RATE= or TOTAL= option in the PROC SURVEYFREQ statement.

When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variance among PSUs. For a multistage sample design, the variance estimation method depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

**Stratification**

If your sample design is stratified at the first stage of sampling, use the STRATA statement to name variables that form the strata. The combinations of categories of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently. If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. If you do not specify a STRATA statement, PROC SURVEYFREQ assumes there is no stratification at the first stage.

**Clustering**

If your sample design selects clusters at the first stage of sampling, use the CLUSTER statement to name variables that identify the first-stage clusters, or primary sampling units (PSUs). The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.
If your sample design has clustering at multiple stages, you should specify only the first-stage clusters, or PSUs, in the CLUSTER statement. PROC SURVEYFREQ assumes that each cluster defined by the CLUSTER statement variables represents a PSU in the sample, and that each observation belongs to one PSU. If you do not specify a CLUSTER statement, the procedure treats each observation as a PSU.

**Weighting**

If your sample design includes unequal weighting, use the WEIGHT statement to name the variable that contains the sampling weights. If you do not specify a WEIGHT statement, PROC SURVEYFREQ assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 4205 for more information.

**Population Totals and Sampling Rates**

If your analysis needs to include a finite population correction (fpc), you can input either the sampling rate or the population total using the RATE= option or the TOTAL= option in the PROC SURVEYFREQ statement. (You cannot specify both of these options in the same PROC SURVEYFREQ statement.) If you do not specify one of these options, the procedure does not use the fpc when computing variance estimates. For fairly small sampling fractions, it is appropriate to ignore this correction. Refer to Cochran (1977) and Kish (1965).

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you should use the RATE=value option or the TOTAL=value option. If your sample design is stratified with different sampling rates or population totals in the strata, then you can use the RATE=SAS-data-set option or the TOTAL=SAS-data-set option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a secondary data set, as opposed to the primary data set that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. Furthermore, the BY groups must appear in the same order as in the primary data set. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=SAS-data-set option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. Alternatively, if you specify the RATE=SAS-data-set option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.
The value in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify value as a number between 0 and 1. Or you can specify value in percentage form as a number between 1 and 100, and PROC SURVEYFREQ will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=value option, value must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

**Domain Analysis**

PROC SURVEYFREQ provides domain analysis through its multiway table capability. Domain Analysis refers to the computation of statistics for subpopulations, or domains, in addition to the computation of statistics for the entire study population. Formation of these domains may be unrelated to the sample design, so the domain sample sizes may actually be random variables. Domain analysis takes into account this variability, using the entire sample when estimating variance for domain estimates. This is also known as subgroup analysis, subpopulation analysis, or subdomain analysis. For more information on domain analysis, refer to Lohr (1999), Cochran (1977), and Fuller et al. (1989).

To request domain analysis with PROC SURVEYFREQ, you should include the domain variable(s) in your TABLES statement request. For example, specifying DOMAIN * A * B in a TABLES statement produces separate two-way tables of A by B for each level of DOMAIN. If your domains are formed by more than one variable, you can specify DomainVariable_1 * DomainVariable_2 * A * B, for example, to obtain two-way tables of A by B for each domain formed by the different combinations of levels for DomainVariable_1 and DomainVariable_2.

Including the domain variables in a TABLES statement request gives a different analysis from that obtained by using a BY statement, which provides completely separate analyses of the BY groups. The BY statement can also be used to analyze the dataset by subgroups, but it is critical to note that this will not produce a valid domain analysis. The BY statement is only appropriate when the number of units in each subgroup is known with certainty; when the subgroup sample size is a random variable, include the domain variables in your TABLES statement request.

**Missing Values**

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYFREQ excludes that observation from the analysis.

An observation is also excluded from the analysis if it has a missing value for any STRATA or CLUSTER variable, unless you specify the MISSING option in the PROC SURVEYFREQ statement. The MISSING option requests that the procedure treat missing values as a valid category for all categorical variables, which include strata variables, cluster variables, and classification or table variables.

Additionally, PROC SURVEYFREQ excludes an observation from a crosstabulation table (and any associated analyses) if that observation has a missing value for any
of the table variables, unless you specify the MISSING option. When the procedure
excludes observations with missing values from a table, it displays the total frequency
of missing observations below that table. With the MISSING option, the procedure
treats the missing values as a valid category and includes them in calculations of
percentages and other statistics.

If all values in a stratum are excluded from the analysis of a table as missing values,
then that stratum is called an empty stratum. Empty strata are not counted in the total
number of strata for the table, which is used to determine the degrees of freedom for
certainty limits and tests. Similarly, empty clusters and missing observations are
not included in the total counts of clusters and observations used in the analysis of
the table.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS sum-
mary table that contains the number of (nonmissing) observations, strata, and clusters
that are included in the analysis of the requested table. When there are missing ob-
servations, empty strata, or empty clusters for the requested table, then these numbers in
the “Table Summary” differ from the total number of observations, strata, and clus-
ters that are present in the input data set and reported in the “Data Summary.” See
Example 68.3 on page 4236 for more information on the “Table Summary.”

If you have missing values in your survey data for any reason (such as nonresponse),
this can compromise the quality of your survey results. An observation without miss-
ing values is called a complete respondent, and an observation with missing values is
called an incomplete respondent. If the complete respondents are different from the
incomplete respondents with regard to a survey effect or outcome, then survey esti-
mates will be biased and will not accurately represent the survey population. There
are a variety of techniques in sample design and survey operations that can reduce
nonresponse. Once data collection is complete, you can use imputation to replace
missing values with acceptable values, and you can use sampling weight adjustments
to compensate for nonresponse. You should complete this data preparation and ad-
justment before you analyze your data with PROC SURVEYFREQ. Refer to Cochran

**Statistical Computations**

The SURVEYFREQ procedure uses the Taylor series expansion method to estimate
standard errors of estimators of proportions for crosstabulation tables. For sample
survey data, the proportion estimator is a ratio estimator formed from estimators of
totals. For example, to estimate the proportion in a crosstabulation table cell, the
procedure uses the ratio of the estimator of the cell total frequency to the estima-
tor of the overall population total, where these totals are linear statistics computed
from the survey data. The Taylor series expansion method obtains a first-order lin-
ear approximation for the ratio estimator and then uses the variance estimate for this
approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller
1975).

When there are clusters, or PSUs, in the sample design, the procedure estimates vari-
one from the variance among PSUs. When the design is stratified, the procedure
combines stratum variance estimates to compute the overall variance estimate. For a
multistage sample design, the variance estimation method depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

In addition to this required sample design information, you also need to specify the sampling weights for a valid analysis, if the weights are not equal. Quite often in complex surveys, respondents have unequal weights, which reflect unequal selection probabilities and adjustments for nonresponse.

**Definitions and Notation**

For a stratified clustered sample design, define the following:

\[ h = 1, 2, \ldots, H \]  
the stratum number, with a total of \( H \) strata

\[ i = 1, 2, \ldots, n_h \]  
the cluster number within stratum \( h \), with a total of \( n_h \) sample clusters from stratum \( h \)

\[ j = 1, 2, \ldots, m_{hi} \]  
the unit number within cluster \( i \) of stratum \( h \), with a total of \( m_{hi} \) sample units from cluster \( i \) of stratum \( h \)

\[ n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi} \]  
the total number of observations in the sample

\[ f_h = \text{first-stage sampling rate for stratum } h \]

\[ W_{hij} = \text{sampling weight of unit } j \text{ in cluster } i \text{ of stratum } h \]

The sampling rate \( f_h \) is the fraction of first-stage units (PSUs) selected for the sample. You can specify the stratum sampling rates with the `RATE=` option. Or if you specify population totals with the `TOTAL=` option, PROC SURVEYFREQ computes \( f_h \) as the ratio of stratum sample size to the stratum total, in terms of PSUs. See the section “Population Totals and Sampling Rates” on page 4204 for details. If you do not specify the `RATE=` option or the `TOTAL=` option, then the procedure assumes that the stratum sampling rates \( f_h \) are negligible and does not use a finite population correction when computing variances.

This notation is also applicable to other sample designs. For example, for a design without stratification, you can let \( H = 1 \); for a sample design without clustering, you can let \( m_{hi} = 1 \) for every \( h \) and \( i \), replacing clusters with individual sampling units.
For a two-way table representing the crosstabulation of two variables, define the following, where there are $R$ levels of the row variable and $C$ levels of the column variable:

$$
\begin{align*}
    r &= 1, 2, \ldots, R \quad \text{is the row number, with a total of } R \text{ rows} \\
    c &= 1, 2, \ldots, C \quad \text{is the column number, with a total of } C \text{ columns} \\
    N_{rc} &= \quad \text{is the population total in row } r \text{ and column } c \\
    N_r &= \sum_{c=1}^{C} N_{rc} \quad \text{is the total in row } r \\
    N_c &= \sum_{r=1}^{R} N_{rc} \quad \text{is the total in column } c \\
    N &= \sum_{r=1}^{R} \sum_{c=1}^{C} N_{rc} \quad \text{is the overall total} \\
    P_{rc} &= \frac{N_{rc}}{N} \quad \text{is the population proportion in row } r \text{ and column } c \\
    P_r &= \frac{N_r}{N} \quad \text{is the proportion in row } r \\
    P_c &= \frac{N_c}{N} \quad \text{is the proportion in column } c \\
    P_{rc}^r &= \frac{N_{rc}}{N_r} \quad \text{is the row proportion for cell } (r, c) \\
    P_{rc}^c &= \frac{N_{rc}}{N_c} \quad \text{is the column proportion for cell } (r, c)
\end{align*}
$$

For a specified observation (identified by stratum, cluster, and unit number within the cluster), define the following to indicate whether or not that observation belongs to cell $(r, c)$, row $r$ and column $c$, of the two-way table, for $r = 1, 2, \ldots, R$ and $c = 1, 2, \ldots, C$:

$$
\delta_{hij}(r, c) = \begin{cases} 
1 & \text{if observation } (hij) \text{ is in cell } (r, c) \\
0 & \text{otherwise}
\end{cases}
$$

Similarly, define the following functions to indicate the observation’s row classification and the observation’s column classification.

$$
\delta_{hij}(r) = \begin{cases} 
1 & \text{if observation } (hij) \text{ is in row } r \\
0 & \text{otherwise}
\end{cases}
$$

$$
\delta_{hij}(c) = \begin{cases} 
1 & \text{if observation } (hij) \text{ is in column } c \\
0 & \text{otherwise}
\end{cases}
$$
**Totals**

PROC SURVEYFREQ estimates population frequency totals for the specified crosstabulation tables, including totals for two-way table cells, rows, columns, and overall totals. The procedure computes the estimate of the total frequency in table cell \((r, c)\) as the weighted frequency sum

\[
\hat{N}_{rc} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) \cdot W_{hij}
\]

Similarly, PROC SURVEYFREQ computes estimates of the row totals, column totals, and overall totals as

\[
\hat{N}_r = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r) \cdot W_{hij}
\]

\[
\hat{N}_c = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(c) \cdot W_{hij}
\]

\[
\hat{N} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij}
\]

The estimators of totals are linear sample statistics, and so their variances can be estimated directly, without the Taylor series approximation that is used for proportions. PROC SURVEYFREQ estimates the variance of the total frequency in table cell \((r, c)\) as

\[
\hat{\text{Var}}(\hat{N}_{rc}) = \sum_{h=1}^{H} \hat{\text{Var}}_h(\hat{N}_{rc})
\]

where if \(n_h > 1\),

\[
\hat{\text{Var}}_h(\hat{N}_{rc}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^h - \bar{n}_{rc}^h)^2
\]

\[
n_{rc}^h = \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) \cdot W_{hij}
\]

\[
\bar{n}_{rc}^h = \frac{\sum_{i=1}^{n_h} n_{rc}^hi}{n_h}
\]

and if \(n_h = 1\),

\[
\hat{\text{Var}}_h(\hat{N}_{rc}) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H 
\end{cases}
\]
The standard deviation of the total is computed as
\[
\text{Std}(\hat{N}_{rc}) = \sqrt{\text{Var}(\hat{N}_{rc})}
\]

The variances and standard deviations are computed in a similar manner for row totals, column totals, and overall table totals.

**Covariance of Totals**

PROC SURVEYFREQ estimates the covariance between total frequency estimates for table cells \((r, c)\) and \((a, b)\) as
\[
\hat{\text{Cov}}(\hat{N}_{rc}, \hat{N}_{ab}) = \sum_{h=1}^{H} \left( \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^{h}) (n_{ab}^{hi} - \bar{n}_{ab}^{h}) \right)
\]

The estimated covariance matrix of the table cell totals \(\hat{N}_{rc}\) is an \(r \times c\) matrix \(\hat{\text{V}}(\hat{N})\), which contains the pair-wise table cell covariances \(\hat{\text{Cov}}(\hat{N}_{rc}, \hat{N}_{ab})\), for \(r = 1, \ldots, R;\ c = 1, \ldots, C;\ a = 1, \ldots, R;\ \text{and} b = 1, \ldots, C.\)

**Proportions**

PROC SURVEYFREQ computes the estimate of the proportion in table cell \((r, c)\) as the ratio of the estimated total for the table cell to the estimated overall total,
\[
\hat{P}_{rc} = \frac{\hat{N}_{rc}}{\hat{N}} = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij}}
\]

Using the Taylor series expansion method, PROC SURVEYFREQ estimates the variance of this proportion estimate as
\[
\hat{\text{Var}}(\hat{P}_{rc}) = \sum_{h=1}^{H} \hat{\text{Var}}_h(\hat{P}_{rc})
\]
where if \(n_h > 1\),
\[
\hat{\text{Var}}_h(\hat{P}_{rc}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (\hat{e}_{rc}^{hi} - \bar{e}_{rc}^{h})^2
\]
\[
\hat{e}_{rc}^{hi} = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \hat{P}_{rc}) W_{hij} \right) / \hat{N}
\]
\[
\bar{e}_{rc}^{h} = \sum_{i=1}^{n_h} e_{rc}^{hi} / n_h
\]
and if \( n_h = 1 \),

\[
\hat{\text{Var}}_h(\hat{P}_{rc}) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H 
\end{cases}
\]

The standard error of the proportion is computed as

\[
\text{StdErr}(\hat{P}_{rc}) = \sqrt{\hat{\text{Var}}(\hat{P}_{rc})}
\]

Similarly, the estimate of the proportion in row \( r \) is

\[
\hat{P}_r = \frac{\hat{N}_{rc}}{\hat{N}}
\]

And its variance estimate is

\[
\hat{\text{Var}}(\hat{P}_r) = \sum_{h=1}^{H} \hat{\text{Var}}_h(\hat{P}_r)
\]

where if \( n_h > 1 \),

\[
\hat{\text{Var}}_h(\hat{P}_r) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{r \cdot i}^h - \hat{e}_r^h)^2
\]

\[
e_{r \cdot i}^h = \left( \sum_{j=1}^{m_{hi}} \left( \delta_{hij}(r) - \hat{P}_r \right) W_{hij} \right) / \hat{N}
\]

\[
\hat{e}_r^h = \sum_{i=1}^{n_h} e_{r \cdot i}^h / n_h
\]

and if \( n_h = 1 \),

\[
\hat{\text{Var}}_h(\hat{P}_r) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H 
\end{cases}
\]

The standard error of the proportion in row \( r \) is computed as

\[
\text{StdErr}(\hat{P}_r) = \sqrt{\hat{\text{Var}}(\hat{P}_r)}
\]

Computations for the proportion in column \( c \) are done in the same way.
Row and Column Proportions

PROC SURVEYFREQ computes the estimate of the row proportion for table cell 
\((r, c)\) as the ratio of the estimated total for the table cell to the estimated total for 
row \(r\),

\[
\hat{P}_{rc}^r = \frac{\hat{N}_{rc}}{\hat{N}_r} = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}}{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r) W_{hij}}
\]

Again using the Taylor series expansion method, PROC SURVEYFREQ estimates 
the variance of this row proportion estimate as

\[
\hat{\text{Var}}(\hat{P}_{rc}^r) = \sum_{h=1}^{H} \hat{\text{Var}}_h(\hat{P}_{rc}^r)
\]

where if \(n_h > 1\),

\[
\hat{\text{Var}}_h(\hat{P}_{rc}^r) = \frac{n_h(1-f_h)}{n_h - 1} \sum_{i=1}^{n_h} (g_{rc}^i - \bar{g}_{rc}^h)^2
\]

\[
g_{rc}^h = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \hat{P}_{rc}^r \delta_{hij}(r) W_{hij}) \right) / \hat{N}_r.
\]

\[
\bar{g}_{rc}^h = \frac{\sum_{i=1}^{n_h} g_{rc}^i}{n_h}
\]

and if \(n_h = 1\),

\[
\hat{\text{Var}}_h(\hat{P}_{rc}^r) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H
\end{cases}
\]

The standard error of the row proportion is computed as

\[
\text{StdErr}(\hat{P}_{rc}^r) = \sqrt{\hat{\text{Var}}(\hat{P}_{rc}^r)}
\]

Similarly, PROC SURVEYFREQ estimates the column proportion for table cell 
\((r, c)\) as the ratio of the estimated total for the table cell to the estimated total for column \(c\),

\[
\hat{P}_{rc}^c = \frac{\hat{N}_{rc}}{\hat{N}_c} = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}}{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(c) W_{hij}}
\]
The variance estimate for the column proportion is computed as described above for the row proportion, but with

\[ g_{rc}^{hi} = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r,c) - \hat{P}_{rc} \hat{\delta}_{hij}(c)) \right) W_{hij} / \hat{N}_c \]

**Confidence Limits**

If you specify the CL option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the proportions in the frequency and crosstabulation tables. The confidence coefficient is determined according to the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

For the proportion in table cell \((r, c)\), the confidence limits are computed as

\[ \hat{P}_{rc} \pm t_{df, \alpha/2} \cdot \text{StdErr}(\hat{P}_{rc}) \]

where \(\hat{P}_{rc}\) is the estimate of the proportion in table cell \((r, c)\), \(\text{StdErr}(\hat{P}_{rc})\) is the standard error of the estimate, and \(t_{df, \alpha/2}\) is the 100\((1 - \alpha/2)\) percentile of the \(t\) distribution with \(df\) degrees of freedom calculated as described in the “Degrees of Freedom” section on page 4214. The confidence limits for row proportions and column proportions are computed similarly to the confidence limits for table cell proportions.

If you specify the CLWT option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the weighted frequencies, or totals, in the crosstabulation tables.

For the total in table cell \((r, c)\), the confidence limits are computed as

\[ \hat{N}_{rc} \pm t_{df, \alpha/2} \cdot \text{StdErr}(\hat{N}_{rc}) \]

where \(\hat{N}_{rc}\) is the estimate of the total frequency in table cell \((r, c)\), \(\text{StdErr}(\hat{N}_{rc})\) is the standard error of the estimate, and \(t_{df, \alpha/2}\) is the 100\((1 - \alpha/2)\) percentile of the \(t\) distribution with \(df\) degrees of freedom calculated as described in the “Degrees of Freedom” section on page 4214. The confidence limits for row totals, column totals, and the overall total are computed similarly to the confidence limits for table cell totals.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS summary table that contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, this table also contains the degrees of freedom \(df\) and the value of \(t_{df, \alpha/2}\) used to compute the confidence limits. See Example 68.3 on page 4236 for more information on the table summary.
Degrees of Freedom

To compute confidence limits for proportions and totals, PROC SURVEYFREQ uses the $100(1 - \alpha/2)$ percentile from the $t$ distribution with $df$ degrees of freedom. PROC SURVEYFREQ calculates the degrees of freedom for $t$ as the number of clusters minus the number of strata. If there are no clusters, then $df$ equals the number of observations minus the number of strata. If the design is not stratified, then $df$ equals the number of clusters minus one. If missing values or missing weights are present in the data, the number of strata, the number of observations, and the number of clusters are counted based on the observations in nonempty strata. See the section “Missing Values” on page 4205 for details.

For the Wald $F$ statistics, PROC SURVEYFREQ also calculates the denominator degrees of freedom as the number of clusters minus the number of strata. Alternatively you can specify the denominator degrees of freedom for these tests with the DDF= option in the TABLES statement. See the section “Wald Chi-Square Test” on page 4221 and the section “Wald Log-Linear Chi-Square Test” on page 4223 for details.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS summary table that contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits or chi-square tests, this table also contains the degrees of freedom $df$. See Example 68.3 on page 4236 for more information on the table summary.

Coefficient of Variation

If you specify the CV option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the proportion estimates in the frequency and crosstabulation tables. The coefficient of variation is the ratio of the standard error to the estimate.

For the proportion in table cell $(r, c)$, the coefficient of variation is computed as

$$CV(\hat{P}_{rc}) = \text{StdErr}(\hat{P}_{rc}) / \hat{P}_{rc}$$

where $\hat{P}_{rc}$ is the estimate of the proportion in table cell $(r, c)$, and StdErr($\hat{P}_{rc}$) is the standard error of the estimate. The coefficients of variation for row proportions and column proportions are computed similarly.

If you specify the CVWT option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the weighted frequencies, or estimated totals, in the crosstabulation tables. For the total in table cell $(r, c)$, the coefficient of variation is computed as

$$CV(\hat{N}_{rc}) = \text{StdErr}(\hat{N}_{rc}) / \hat{N}_{rc}$$

where $\hat{N}_{rc}$ is the estimate of the total in table cell $(r, c)$, and StdErr($\hat{N}_{rc}$) is the standard error of the estimate. The coefficients of variation for row totals, column totals, and the overall total are computed similarly.
**Design Effect**

If you specify the **DEFF** option in the TABLES statement, PROC SURVEYFREQ computes design effects for the overall proportion estimates in the frequency and crosstabulation tables. The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. Refer to Lohr (1999) and Kish (1965).

The design effect for the proportion in table cell \((r, c)\) is computed as

\[
\text{DEFF}(\hat{P}_{rc}) = \frac{\text{Var}(\hat{P}_{rc})}{\text{Var}_{SRS}(\hat{P}_{rc})} = \frac{\text{Var}(\hat{P}_{rc})}{\left\{ (1 - f) \hat{P}_{rc} (1 - \hat{P}_{rc}) / (n - 1) \right\}}
\]

where \(\hat{P}_{rc}\) is the estimate of the proportion in table cell \((r, c)\), \(\text{Var}(\hat{P}_{rc})\) is the variance of the estimate, \(f\) is the overall sampling fraction, and \(n\) is the number of observations in the sample.

PROC SURVEYFREQ determines the value of \(f\), the overall sampling fraction, based on the **RATE=** and **TOTAL=** options. If you do not specify either of these options, then PROC SURVEYFREQ assumes the value of \(f\) is negligible and does not use a finite population correction in the analysis, as described in the section “Population Totals and Sampling Rates” on page 4204. If you specify **RATE=value**, then PROC SURVEYFREQ uses this value for the overall sampling fraction \(f\). If you specify **TOTAL=value**, then PROC SURVEYFREQ computes \(f\) as the ratio of the number of PSUs in the sample to the specified total.

If you specify stratum sampling rates with the **RATE=SAS-data-set** option, then PROC SURVEYFREQ computes stratum totals based on these stratum sampling rates and the number of sample PSUs in each stratum. The procedure sums the stratum totals to form the overall total, and computes \(f\) as the ratio of the number of sample PSUs to the overall total. Alternatively, if you specify stratum totals with the **TOTAL=SAS-data-set** option, then PROC SURVEYFREQ sums these totals to compute the overall total. The overall sampling fraction \(f\) is then computed as the ratio of the number of sample PSUs to the overall total.

**Expected Weighted Frequency**

If you specify the **EXPECTED** option in the TABLES statement, PROC SURVEYFREQ displays expected weighted frequencies for the table cells in two-way tables. The expected weighted frequencies are computed under the null hypothesis that the row and column variables are independent, as

\[
E_{rc} = \hat{N}_r \cdot \hat{N}_c / \hat{N}
\]

where \(\hat{N}_r\) is the estimated total for row \(r\), \(\hat{N}_c\) is the estimated total for column \(c\), and \(\hat{N}\) is the estimated overall total. Equivalently,

\[
E_{rc} = \hat{P}_r \cdot \hat{P}_c \cdot \hat{N}
\]
These expected values are used in the design-based chi-square tests of independence, as described in “Rao-Scott Chi-Square Test” and the section “Wald Chi-Square Test” on page 4221.

**Rao-Scott Chi-Square Test**

The Rao-Scott chi-square test is a design-adjusted version of the Pearson chi-square test, which involves differences between observed and expected frequencies. For two-way tables, the null hypothesis for this test is no association between the row and column variables. For one-way tables, the Rao-Scott chi-square tests the null hypothesis of equal proportions, or you can specify null proportions for one-way tables with the TESTP= option.

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott chi-square test with the CHISQ option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified chi-square test, with the CHISQ1 option.

**Two-Way Tables**

The Rao-Scott chi-square statistic is computed from the Pearson chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association between the row and column variables, this statistic approximately follows a chi-square distribution with \((R - 1)(C - 1)\) degrees of freedom. An F approximation is also given.

The Rao-Scott chi-square is computed as

\[
Q_{RS} = Q_P / D
\]

where \(D\) is the design correction described in the “Design Correction for Two-Way Tables” section on page 4217, and \(Q_P\) is the Pearson chi-square based on the estimated totals.

\[
Q_P = \sum_r \sum_c (\hat{N}_{rc} - E_{rc})^2 / E_{rc}
\]

where \(\hat{N}_{rc}\) is the estimated total for table cell \((r, c)\), and \(E_{rc}\) is the expected total for cell \((r, c)\) under the null hypothesis of no association,

\[
E_{rc} = \hat{N}_r \cdot \hat{N}_c / \hat{N}
\]

Under the null hypothesis of no association, the Rao-Scott chi-square \(Q_{RS}\) approximately follows a chi-square distribution with \((R - 1)(C - 1)\) degrees of freedom. A better approximation may be obtained by the F statistic

\[
F = Q_{RS} / (R - 1)(C - 1)
\]
which has an $F$ distribution with $(R - 1)(C - 1)$ and $(R - 1)(C - 1)\kappa$ degrees of freedom under the null hypothesis, where $\kappa$ equals the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214.

**Design Correction for Two-Way Tables**

If you specify the CHISQ option, the design correction is computed from the estimated proportions, as

$$D = \left\{ \sum_r \sum_c (1 - \hat{P}_{rc}) \text{DEFF}(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_r) \text{DEFF}(\hat{P}_r) \right\} / (R - 1)(C - 1)$$

where

$$\text{DEFF}(\hat{P}_{rc}) = \frac{\text{Var}(\hat{P}_{rc})}{\text{Var}_{SRS}(\hat{P}_{rc})}$$

as described in the section “Design Effect” on page 4215. $\hat{P}_{rc}$ is the estimate of the proportion in table cell $(r, c)$, $\text{Var}(\hat{P}_{rc})$ is the variance of the estimate, $f$ is the overall sampling fraction, and $n$ is the number of observations in the sample. $\text{DEFF}(\hat{P}_r)$, the design effect for the estimate of the proportion in row $r$, and $\text{DEFF}(\hat{P}_c)$, the design effect for the estimate of the proportion in row $c$, are computed similarly.

If you specify the CHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions, computed as the product of the corresponding estimated row and cell proportions.

$$D_0 = \left\{ \sum_r \sum_c (1 - P_{rc}^0) \text{DEFF}_0(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_r) \text{DEFF}(\hat{P}_r) \right\} / (R - 1)(C - 1)$$

where

$$P_{rc}^0 = \hat{P}_r \cdot \hat{P}_c$$

and

$$\text{DEFF}_0(\hat{P}_{rc}) = \frac{\text{Var}(\hat{P}_{rc})}{\text{Var}_{SRS}(P_{rc}^0)}$$

as

$$\text{DEFF}_0(\hat{P}_{rc}) = \frac{\text{Var}(\hat{P}_{rc})}{\text{Var}_{SRS}(P_{rc}^0)}$$

where

$$P_{rc}^0 = \hat{P}_r \cdot \hat{P}_c$$
One-Way Tables

For one-way tables, the Rao-Scott chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the TESTP= option, PROC SURVEYFREQ computes the goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott chi-square statistic approximately follows a chi-square distribution with \((C - 1)\) degrees of freedom for a table with \(C\) levels. PROC SURVEYFREQ also computes an \(F\) statistic that may provide a better approximation.

The Rao-Scott chi-square is computed as

\[
Q_{RS} = \frac{Q_P}{D}
\]

where \(D\) is the design correction described in the section “Design Correction for One-Way Tables” on page 4219, and \(Q_P\) is the Pearson chi-square based on the estimated totals,

\[
Q_P = \sum_c \frac{(\hat{N}_c - E_c)^2}{E_c}
\]

where \(E_c\) is the expected total for level \(c\) under the null hypothesis. For the null hypothesis of equal proportions,

\[
E_c = \frac{\hat{N}}{C}
\]

For specified null proportions,

\[
E_c = \frac{\hat{N}}{C} \cdot P_c^0
\]

where \(P_c^0\) is the null proportion for level \(c\).

Under the null hypothesis, the one-way Rao-Scott chi-square \(Q_{RS}\) approximately follows a chi-square distribution with \((C - 1)\) degrees of freedom. A better approximation may be obtained by the \(F\) statistic

\[
F = \frac{Q_{RS}}{(C - 1)}
\]

which has an \(F\) distribution with \((C - 1)\) and \((C - 1)\kappa\) degrees of freedom under the null hypothesis, where \(\kappa\) equals the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214.
Design Correction for One-Way Tables

If you specify the CHISQ option, the design correction is computed from the estimated proportions, as

$$D = \sum_c (1 - \hat{P}_c) \text{DEFF}(\hat{P}_c) / (C - 1)$$

where

$$\text{DEFF}(\hat{P}_c) = \hat{\text{Var}}(\hat{P}_c) / \left\{ (1 - f) \hat{P}_c (1 - \hat{P}_c) / (n - 1) \right\}$$

\(\hat{P}_c\) is the proportion estimate for table level \(c\), \(\hat{\text{Var}}(\hat{P}_c)\) is the variance of the estimate, \(f\) is the overall sampling fraction, and \(n\) is the number of observations in the sample.

If you specify the CHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis proportions – either equal proportions for all levels, or the proportions you specify with the TESTP= option.

$$D_0 = \sum_c (1 - P^0_c) \text{DEFF}_0(\hat{P}_c) / (C - 1)$$

where

$$\text{DEFF}_0(\hat{P}_c) = \hat{\text{Var}}(\hat{P}_c) / \left\{ (1 - f) P^0_c (1 - P^0_c) / (n - 1) \right\}$$

and \(P^0_c = 1/C\) for equal proportions, or \(P^0_c\) takes the value specified with the TESTP= option.

Rao-Scott Likelihood Ratio Chi-Square Test

The Rao-Scott likelihood ratio chi-square test is a design-adjusted version of the likelihood ratio test, which involves ratios between observed and expected frequencies and tests the null hypothesis of no association between the row and column variables in a two-way table. For a one-way tables the null hypothesis is equal proportions for the table levels, or you can specify other null proportions with the TESTP= option. Refer to Lohr (1999), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987).

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott likelihood ratio test with the LRCHISQ option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified likelihood ratio test, with the LRCHISQ1 option.
Two-Way Tables

The Rao-Scott likelihood ratio statistic is computed from the likelihood ratio chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association, this statistic approximately follows a chi-square distribution with \((R-1)(C-1)\) degrees of freedom. An F approximation is also given.

The Rao-Scott likelihood ratio chi-square is computed as

\[ G_{RS}^2 = G^2 / D \]

where \(G^2\) is the likelihood ratio chi-square based on the estimated totals, and \(D\) is the design correction.

\[ G^2 = 2 \sum_r \sum_c \hat{N}_{rc} \ln \left( \frac{\hat{N}_{rc}}{E_{rc}} \right) \]

where \(\hat{N}_{rc}\) is the estimated total for table cell \((r, c)\), and \(E_{rc}\) is the expected total for cell \((r, c)\) under the null hypothesis of no association,

\[ E_{rc} = \hat{N}_r \cdot \hat{N}_c / \hat{N} \]

The Rao-Scott likelihood ratio chi-square uses the same design correction \(D\) as the Rao-Scott (Pearson) chi-square uses, which is described in the section “Design Correction for Two-Way Tables” on page 4217. If you specify the LRCHISQ option, the design correction is computed from the estimated proportions. If you specify the LRCHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions, computed as the product of the corresponding estimated row and column proportions.

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square \(G_{RS}^2\) approximately follows a chi-square distribution with \((R-1)(C-1)\) degrees of freedom. A better approximation may be obtained by the F statistic

\[ F = G_{RS}^2 / (R-1)(C-1) \]

which has an F distribution with \((R-1)(C-1)\) and \((R-1)(C-1)\kappa\) degrees of freedom under the null hypothesis, where \(\kappa\) equals the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214.

One-Way Tables

For one-way tables, the Rao-Scott likelihood ratio chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the TESTP= option, PROC SURVEYFREQ computes the goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott likelihood ratio statistic approximately follows a chi-square distribution with \((C-1)\) degrees of freedom for a table with \(C\) levels. An F approximation is also given.

The Rao-Scott likelihood ratio chi-square is computed as

\[ G_{RS}^2 = G^2 / D \]
where $G^2$ is the likelihood ratio chi-square based on the estimated totals, and $D$ is the design correction.

$$G^2 = 2 \sum_c \hat{N}_c \ln \left( \frac{\hat{N}_c}{E_c} \right)$$

where $E_c$ is the expected total for level $c$ under the null hypothesis. For the null hypothesis of equal proportions,

$$E_c = \frac{\hat{N}}{C}$$

For specified null proportions $P^0_c$,

$$E_c = \hat{N} \cdot P^0_c$$

The Rao-Scott likelihood ratio chi-square uses the same design correction $D$ as the Rao-Scott (Pearson) chi-square uses, which is described in the section “Design Correction for One-Way Tables” on page 4219. If you specify the LRCHISQ option, the design correction is computed from the estimated proportions. If you specify the LRCHISQ1 option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions.

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square $G^2_{RS}$ approximately follows a chi-square distribution with $(C - 1)$ degrees of freedom. A better approximation may be obtained by the $F$ statistic

$$F = \frac{G^2_{RS}}{(C - 1)}$$

which has an $F$ distribution with $(C - 1)$ and $(C - 1)\kappa$ degrees of freedom under the null hypothesis, where $\kappa$ equals the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214.

**Wald Chi-Square Test**

PROC SURVEYFREQ provides two Wald chi-square tests for independence of the row and column variables in two-way tables: a Wald chi-square test based on the difference between observed and expected weighted cell frequencies, and a Wald log-linear chi-square test based on the log odds ratio. These statistics test for independence of the row and column variables in two-way tables, taking into account the complex survey design. Refer to Bedrick (1983), Koch, Freeman, and Freeman (1975), and Wald (1943) for information on Wald statistics and their applications to categorical data analysis.

For these two tests, PROC SURVEYFREQ computes the generalized Wald chi-square statistic, the corresponding Wald $F$ statistic, and also an adjusted Wald $F$ statistic for tables larger than $2 \times 2$. Under the null hypothesis of independence, the Wald chi-square statistic approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom for very large samples. However, it has been shown that this test may perform poorly in terms of actual significance level and power, especially for tables with a large number of cells or for samples with a relatively small number of clusters. Refer to Thomas and Rao (1984 and 1985) and Lohr (1999) for more
information. Refer to Felligi (1980) and Hidiroglou, Fuller, and Hickman (1980) for information on the adjusted Wald \( F \) statistic. Thomas and Rao (1984) found that the adjusted Wald \( F \) statistic provides a more stable test than the chi-square statistic, although its power may be low when the number of sample clusters is not large. Refer also to Korn and Graubard (1990) and Thomas, Singh, and Roberts (1996).

If you specify the WCHISQ option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence in the two-way table based on the differences between the observed (weighted) cell frequencies and the expected frequencies.

Under the null hypothesis of independence of the row and column variables, the expected cell frequencies are computed as

\[
E_{rc} = \hat{N}_r \cdot \hat{N}_c / \hat{N}
\]

where \( \hat{N}_r \) is the estimated total for row \( r \), \( \hat{N}_c \) is the estimated total for column \( c \), and \( \hat{N} \) is the estimated overall total, as described in the section “Expected Weighted Frequency” on page 4215. And the null hypothesis that the population weighted frequencies equal the expected frequencies is

\[
H_0: Y_{rc} = N_{rc} - E_{rc} = 0
\]

for all \( r = 1, \ldots, (R - 1) \) and \( c = 1, \ldots, (C - 1) \). This null hypothesis can be stated equivalently in terms of cell proportions, with the expected cell proportions computed as the products of the marginal row and column proportions.

The generalized Wald chi-square statistic is computed as

\[
Q_{Wald} = \hat{Y}' (H \hat{V}(\hat{N}) H')^{-1} \hat{Y}
\]

where \( \hat{Y} \) is the \((R - 1)(C - 1)\) array of the differences between the observed and expected weighted frequencies \( (\hat{N}_{rc} - E_{rc}) \), and \( (H \hat{V}(\hat{N}) H') \) estimates the variance of \( \hat{Y} \).

\( \hat{V}(\hat{N}) \) is the covariance matrix of the estimates \( \hat{N}_{rc} \), and its computation is described in the section “Covariance of Totals” on page 4210.

\( H \) is an \((R-1)(C-1)\) by \(RC\) matrix containing the partial derivatives of the elements of \( \hat{Y} \) with respect to the elements of \( \hat{N} \). The elements of \( H \) are computed as follows, where \( a \) denotes a row different from row \( r \), and \( b \) denotes a column different from column \( c \).

\[
\frac{\partial \hat{Y}_{rc}}{\partial \hat{N}_{rc}} = 1 - \left( \hat{N}_r + \hat{N}_c - \hat{N}_r \cdot \hat{N}_c / \hat{N} \right) / \hat{N}
\]

\[
\frac{\partial \hat{Y}_{rc}}{\partial \hat{N}_{ac}} = - \left( \hat{N}_r - \hat{N}_r \cdot \hat{N}_c / \hat{N} \right) / \hat{N}
\]

\[
\frac{\partial \hat{Y}_{rc}}{\partial \hat{N}_{rb}} = - \left( \hat{N}_c - \hat{N}_r \cdot \hat{N}_c / \hat{N} \right) / \hat{N}
\]

\[
\frac{\partial \hat{Y}_{rc}}{\partial \hat{Y}_{ab}} = \hat{N}_r \cdot \hat{N}_c / \hat{N}^2
\]
Under the null hypothesis of independence, the statistic $Q_{Wald}$ approximately follows a chi-square distribution with $(R - 1)(C - 1)$ degrees of freedom for very large samples.

PROC SURVEYFREQ computes the Wald $F$ statistic as

$$F_{Wald} = \frac{Q_{Wald}}{(R - 1)(C - 1)}$$

Under the null hypothesis of independence, $F_{Wald}$ approximately follows an $F$ distribution with $(R - 1)(C - 1)$ numerator degrees of freedom. By default, PROC SURVEYFREQ computes the denominator degrees of freedom as the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214. Alternatively, you can specify the denominator degrees of freedom with the DDF= option in the TABLES statement.

For tables larger than $2 \times 2$, PROC SURVEYFREQ also computes the adjusted Wald $F$ statistic

$$F_{Adj\ Wald} = \frac{s - k + 1}{k} \frac{Q_{Wald}}{s}$$

where $k = (R - 1)(C - 1)$, and $s$ is the number of clusters minus the number of strata. Alternatively, you can specify the value of $s$ with the DDF= option in the TABLES statement. Note that for $2 \times 2$ tables, $k = (R - 1)(C - 1) = 1$, so the the adjusted Wald $F$ statistic equals the (unadjusted) Wald $F$ statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis, $F_{Adj\ Wald}$ approximately follows an $F$ distribution with $k$ numerator degrees of freedom and $(s - k + 1)$ denominator degrees of freedom.

### Wald Log-Linear Chi-Square Test

If you specify the WLLCHISQ option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence based on the log odds ratios. See the section “Wald Chi-Square Test” on page 4221 for more information on Wald tests.

For a two-way table of $R$ rows and $C$ columns, the Wald log-linear test is based on the $(R - 1)(C - 1)$ array of

$$\tilde{Y}_{rc} = \log \hat{N}_{rc} - \log \hat{N}_{rC} - \log \hat{N}_{RC} + \log \hat{N}_{Rc}$$

where $\hat{N}_{rc}$ is the estimated total for table cell $(r, c)$. The null hypothesis of independence between the row and column variables is $H_0: Y_{rc} = 0$ for all $r = 1, \ldots (R - 1)$ and $c = 1, \ldots (C - 1)$. This null hypothesis can be stated equivalently in terms of cell proportions.
The generalized Wald log-linear chi-square statistic is computed as

\[ Q_{\text{Wald LL}} = \hat{Y}' \hat{V}(\hat{Y})^{-1} \hat{Y} \]

where \( \hat{Y} \) is the \((R - 1)(C - 1)\) array of the \( \hat{Y}_{rc} \), and \( \hat{V}(\hat{Y}) \) estimates the variance of \( \hat{Y} \).

\[ \hat{V}(\hat{Y}) = A D^{-1} \hat{V}(\hat{N}) D^{-1} A' \]

where \( \hat{V}(\hat{N}) \) is the covariance matrix of the estimates \( \hat{N}_{rc} \), as described in the section “Covariance of Totals” on page 4210, \( D \) is a diagonal matrix with the estimated totals \( \hat{N}_{rc} \) on the diagonal, and \( A \) is the \((R - 1)(C - 1)\) by \( RC \times RC \) linear contrast matrix.

Under the null hypothesis of independence, the statistic \( Q_{\text{Wald LL}} \) approximately follows a chi-square distribution with \((R - 1)(C - 1)\) degrees of freedom for very large samples.

PROC SURVEYFREQ computes the Wald log-linear \( F \) statistic as

\[ F_{\text{Wald LL}} = \frac{Q_{\text{Wald LL}}}{(R - 1)(C - 1)} \]

Under the null hypothesis of independence, \( F_{\text{Wald LL}} \) approximately follows an \( F \) distribution with \((R - 1)(C - 1)\) numerator degrees of freedom. By default, PROC SURVEYFREQ computes the denominator degrees of freedom as the number of clusters minus the number of strata, as described in the section “Degrees of Freedom” on page 4214. Alternatively, you can specify the denominator degrees of freedom with the \texttt{DDF=} option in the TABLES statement.

For tables larger than \( 2 \times 2 \), PROC SURVEYFREQ also computes the adjusted Wald log-linear \( F \) statistic

\[ F_{\text{Adj Wald LL}} = s - k + 1 \frac{Q_{\text{Wald LL}}}{k s} \]

where \( k = (R - 1)(C - 1) \), and \( s \) is the number of clusters minus the number of strata. Alternatively, you can specify the value of \( s \) with the \texttt{DDF=} option in the TABLES statement. Note that for \( 2 \times 2 \) tables, \( k = (R - 1)(C - 1) = 1 \), so the the adjusted Wald \( F \) statistic equals the (unadjusted) Wald \( F \) statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis, \( F_{\text{Adj Wald LL}} \) approximately follows an \( F \) distribution with \( k \) numerator degrees of freedom and \((s - k + 1)\) denominator degrees of freedom.
Displayed Output

Data and Sample Design Summary Table

The “Data Summary” table provides information on the input data set and the sample design. PROC SURVEYFREQ displays this table unless you specify the NOSUMMARY option in the PROC SURVEYFREQ statement.

The “Data Summary” table displays the total number of valid observations. To be considered valid, an observation must have a nonmissing, positive WEIGHT value if you specify a WEIGHT statement. If you do not specify the MISSING option, a valid observation must also have nonmissing values for all STRATA and CLUSTER variables. The number of valid observations may differ from the number of nonmissing observations for an individual analysis variable, which the procedure displays in the frequency or crosstabulation tables. See the section “Missing Values” on page 4205 for more information.

PROC SURVEYFREQ displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a STRATA statement
- Number of Clusters, if you specify a CLUSTER statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a WEIGHT statement

Stratum Information Table

If you specify the LIST option in the STRATA statement, PROC SURVEYFREQ displays a “Stratum Information” table. This table provides the following information for each stratum.

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Number of Observations, which is the number of valid observations in the stratum
- Population Total for the stratum, if you specify the TOTAL= option
- Sampling Rate for the stratum, if you specify the TOTAL= option or the RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of valid observations in the stratum.
- Number of Clusters, which is the number of clusters in the stratum, if you specify a CLUSTER statement
One-Way Frequency Tables

PROC SURVEYFREQ displays one-way frequency tables for all one-way table requests in the TABLES statements, unless you specify the NOPRINT option in the TABLES statement. A one-way table shows the sample frequency distribution of a single variable, and provides estimates for its population distribution in terms of totals and proportions. For each level of the variable, PROC SURVEYFREQ displays the following information in the one-way table:

- Frequency count, giving the number of sample observations for the level
- Weighted Frequency total, estimating the total population frequency for the level
- Standard Deviation of Weighted Frequency
- Percent, estimating the population proportion for the level
- Standard Error of Percent

The one-way table displays weighted frequencies if your analysis includes a WEIGHT statement, or if you specify the WTFREQ option in the TABLES statement.

The one-way table also displays the Frequency Missing, or the number of observations with missing values.

You can suppress the frequency counts by specifying the NOFREQ option in the TABLES statement. Also, the NOWT option suppresses the weighted frequencies and their standard deviations. The NOPERCENT option suppresses the percentages and their standard errors. The NOSTD option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The NOTOTAL option suppresses the total row of the one-way table.

PROC SURVEYFREQ optionally displays the following information for a one-way table:

- Variance of Weighted Frequency, if you specify the VARWT option
- Confidence Limits for Weighted Frequency, if you specify the CLWT option
- Coefficient of Variation for Weighted Frequency, if you specify the CVWT option
- Test Percent, if you specify the TESTP= option
- Variance of Percent, if you specify the VAR option
- Confidence Limits for Percent, if you specify the CL option
- Coefficient of Variation for Percent, if you specify the CV option
- Design Effect for Percent, if you specify the DEFF option
Crosstabulation Tables

PROC SURVEYFREQ displays all multiway table requests in the TABLES statements, unless you specify the NOPRINT option in the TABLES statement. For two-way to multiway crosstabulation tables, the values of the last variable in the table request form the table columns. The values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables form one layer. PROC SURVEYFREQ produces a separate two-way crosstabulation table for each layer.

For each layer, the crosstabulation table displays the row and column variable names and values (or levels). Each two-way table lists levels of the column variable within each level of the row variable.

By default, the procedure displays all levels of the column variable within each level of the row variables, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row levels with zero frequency for that layer. You can suppress the display of zero frequency levels by specifying the NOSPARSE option.

For each combination of variable levels, or table cell, the two-way table displays the following information:

- Frequency, giving the number of observations that have the indicated values of the two variables
- Weighted Frequency total, estimating the total population frequency for the table cell
- Standard Deviation of Weighted Frequency
- Percent, estimating the population proportion for the table cell
- Standard Error of Percent

The two-way table displays weighted frequencies if your analysis includes a WEIGHT statement, or if you specify the WTFREQ option in the TABLES statement.

The two-way table also displays the Frequency Missing, or the number of observations with missing values.

You can suppress the frequency counts by specifying the NOFREQ option in the TABLES statement. Also, the NOWT option suppresses the weighted frequencies and their standard deviations. The NOPERCENT option suppresses the percentages and their standard errors. The NOSTD option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The NOTOTAL option suppresses the row totals and column totals.
PROC SURVEYFREQ optionally displays the following information for a two-way table:

- Expected Weighted Frequency, if you specify the `EXPECTED` option
- Variance of Weighted Frequency, if you specify the `VARWT` option
- Confidence Limits for Weighted Frequency, if you specify the `CLWT` option
- Coefficient of Variation for Weighted Frequency, if you specify the `CVWT` option
- Variance of Percent, if you specify the `VAR` option
- Confidence Limits for Percent, if you specify the `CL` option
- Coefficient of Variation for Percent, if you specify the `CV` option
- Design Effect for Percent, if you specify the `DEFF` option
- Row Percent, estimating the cell’s proportion of the population total for that cell’s row, if you specify the `ROW` option
- Standard Error of Row Percent, if you specify the `ROW` option
- Variance of Row Percent, if you specify the `VAR` option and the `ROW` option
- Confidence Limits for Row Percent, if you specify the `CL` option and the `ROW` option
- Coefficient of Variation for Row Percent, if you specify the `CV` option and the `ROW` option
- Column Percent, estimating the cell’s proportion of the population total for that cell’s column, if you specify the `COL` option
- Standard Error of Column Percent, if you specify the `COL` option
- Variance of Column Percent, if you specify the `VAR` option and the `COL` option
- Confidence Limits for Column Percent, if you specify the `CL` option and the `COL` option
- Coefficient of Variation for Column Percent, if you specify the `CV` option and the `COL` option

If you specify the `ROW` option, the `NOPERCENT` option suppresses the row percentages and their standard errors. The `NOSTD` option suppresses the standard errors of the row percentages. Similarly, if you specify the `COL` option, the `NOPERCENT` option suppresses the column percentages and their standard errors. The `NOSTD` option suppresses the standard errors of the column percentages.
Statistical Tests

If you specify the CHISQ option for the Rao-Scott chi-square test, the CHISQ1 option for the modified test, the LRCHISQ option for the Rao-Scott likelihood ratio chi-square test, or the LRCHISQ1 option for the modified test, PROC SURVEYFREQ displays the following information:

- Pearson Chi-Square, if you specify the CHISQ or CHISQ1 option
- Likelihood Ratio Chi-Square, if you specify the LRCHISQ or LRCHISQ1 option
- Design Correction
- Rao-Scott Chi-Square, if you specify the CHISQ or CHISQ1 option
- Rao-Scott Likelihood Ratio Chi-Square, if you specify the LRCHISQ or LRCHISQ1 option
- DF, the degrees of freedom for the chi-square test
- Pr > ChiSq, the $p$-value for the chi-square test
- F Value
- Num DF, the numerator degrees of freedom for F
- Den DF, the denominator degrees of freedom for F
- Pr > F, the $p$-value for the F test

If you specify the WCHISQ option for the Wald chi-square test or the WLLCHISQ option for the Wald log-linear chi-square test, PROC SURVEYFREQ displays the following information:

- Wald Chi-Square, if you specify the WCHISQ option
- Wald Log-Linear Chi-Square, if you specify the WLLCHISQ option
- F Value
- Num DF, the numerator degrees of freedom for F
- Den DF, the denominator degrees of freedom for F
- Pr > F, the $p$-value for the F test
- Adjusted F Value, for tables larger than $2 \times 2$
- Num DF, the numerator degrees of freedom for Adjusted F
- Den DF, the denominator degrees of freedom for Adjusted F
- Pr > Adj F, the $p$-value for the Adjusted F test
**ODS Table Names**

PROC SURVEYFREQ assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**Examples**

**Example 68.1. Two-Way Tables**

This example uses the SIS_Survey data set from the section “Getting Started” on page 4185. The data set contains results from a customer satisfaction survey for a student information system (SIS).

The following PROC SURVEYFREQ statements request a two-way table for the variables Department by Response and customize the crosstabulation table display.

```plaintext
proc surveyfreq data=SIS_Survey;
  tables Department * Response / cv deff nowt nostd nototal;
  strata State NewUser / list;
  cluster School;
  weight SamplingWeight;
run;
```

The TABLES statement requests a two-way table of Department by Response. The CV option requests coefficients of variation for the percentage estimates. The DEFF option requests design effects for the percentage estimates. The NOWT option suppresses display of the weighted frequencies, and the NOSTD option suppresses display of standard errors for the estimates. The NOTOTAL option suppresses the row totals, column totals, and overall totals.
The WCHISQ option requests a Wald chi-square test of association between the variables Department and Response.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information to the procedure, so that the analysis will be done according to the sample design used for the survey. The STRATA statement names the variables State and NewUser, which identify the first-stage strata. The LIST option in the STRATA statement requests a Stratum Information table. The CLUSTER statement identifies School as the cluster or first-stage sampling unit. The WEIGHT statement names the sampling weight variable.

Output 68.1.1 displays the Data Summary and Stratum Information tables produced by PROC SURVEYFREQ. The Stratum Information table lists the six strata in the survey and shows the number of clusters, or schools, and the number of observations in each stratum.

**Output 68.1.1. Data Summary and Stratum Information**

```
School Information System Survey
The SURVEYFREQ Procedure

Data Summary
Number of Strata          6
Number of Clusters        370
Number of Observations    1850
Sum of Weights           38899.6482

Stratum Information

<table>
<thead>

</tbody>
</table>
```
Output 68.1.2 displays the two-way table of `Department` by `Response`. According to the `TABLES` statement options specified, this two-way table includes coefficients of variation and design effects for the percentage estimates, and it does not show the weighted frequencies or the standard errors of the estimates.

### Output 68.1.2. Two-Way Table of Department by Response

</table>

The following PROC SURVEYFREQ statements request a two-way table of `Department` by `Response` that includes row percentages, and also a Wald chi-square test of association between the two table variables.

```sas
proc surveyfreq data=SIS_Survey nosummary;
tables Department * Response /
   row nowt wchisq;
strata State NewUser;
ccluster School;
weight SamplingWeight;
run;
```

Output 68.1.3 displays the two-way table. The row percentages show the distribution of `Response` for `Department = 'Faculty'` and for `Department = 'Admin/Guidance'`.

Output 68.1.4 displays the Wald chi-square test for association between Department and Response. The Wald chi-square is 11.44, and the corresponding adjusted F value is 2.84 with a p-value of .0243. This indicates a significant association between department (faculty or admin/guidance) and satisfaction with the student information system.

Sample Size = 1850
Example 68.2. Multiway Tables

Continuing to use the SIS_Survey data set from the section “Getting Started” on page 4185, this example shows how to produce multiway tables. The following PROC SURVEYFREQ statements request a table of Department by SchoolType by Response for the student information system survey.

```sas
proc surveyfreq data=SIS_Survey;
  tables Department * SchoolType * Response
          SchoolType * Response;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

The TABLES statement requests a multiway table with SchoolType as the row variable, Response as the column variable, and Department as the layer variable. This request produces a separate two-way table of SchoolType by Response for each level of the variable Department. The TABLES statement also requests a two-way table of SchoolType by Response, which totals the multiway table over both levels of Department. As in the previous examples, the STRATA, CLUSTER, and WEIGHT statements provide sample design information, so that the analysis will be done according to the design used for this survey.

Output 68.2.1 displays the multiway table produced by PROC SURVEYFREQ, which includes a table of SchoolType by Response for Department = 'Faculty' and for Department = 'Admin/Guidance'.
Output 68.2.1. Multiway Table of Department by SchoolType by Response

Example 68.3. Output Data Sets

PROC SURVEYFREQ uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. Using ODS, you can create a SAS data set from any piece of PROC SURVEYFREQ output. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

When selecting tables for ODS output data set, you reference tables by their ODS table names. Each table created by PROC SURVEYFREQ is assigned a name, and the section “ODS Table Names” on page 4230 lists the table names.

To save the one-way table of Response from Figure 68.3 in an output data set, use an ODS OUTPUT statement as follows:

```sas
proc surveyfreq data=SIS_Survey;
tables Response / cl nowt;
ods output OneWay=ResponseTable;
strata State NewUser;
cluster School;
weight SamplingWeight;
run;
```

Output 68.3.1 displays the output data set ResponseTable, which contains the one-way table of Response. This data set has six observations, and each of these observations corresponds to a row of the one-way table. The first five observations correspond to the five levels of Response, as they are ordered in the display, and the last observation corresponds to the overall total, which is the last row of the table. The data set ResponseTable includes a variable corresponding to each column of the one-way table. For example, the variable Percent contains the percentage estimates, and the variables LowerCL and UpperCL contain the lower and upper confidence limits for the percentage estimates.

### Output 68.3.1. ResponseTable Output Data Set

<tr>
<td>6</td>
<td>Table Response</td>
<td>.</td>
<td>1850</td>
<td>100.000</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

PROC SURVEYFREQ also creates a table summary that is not displayed. Some of the information in this table is similar to that contained in the “Data Summary” table, but the table summary describes data used to analyze the specified table, while the data summary describes the entire input data set. Due to missing values, for example, the number of observations (or strata or clusters) used to analyze a particular table may differ from the number of observations (or strata or clusters) reported for the input data set in the “Data Summary” table. See the section “Missing Values” on page...
4205 for more details. If you request confidence limits, the “Table Summary” table also contains the degrees of freedom and the \( t \)-value used to compute the confidence limits.

The following statements store the nondisplayed “Table Summary” table in the output data set ResponseSummary.

```sas
proc surveyfreq data=SIS_Survey;
tables Response / cl nowt;
ods output TableSummary=ResponseSummary;
strata State NewUser;
ccluster School;
weight SamplingWeight;
run;
```

Output 68.3.2 displays the output data set ResponseSummary.

Chapter 69
The SURVEYLOGISTIC Procedure

Overview

Categorical responses arise extensively in survey research. Common examples of responses include

- binary: e.g., attended graduate school or not
- ordinal: e.g., mild, moderate, and severe pain
- nominal: e.g., ABC, NBC, CBS, FOX TV network viewed at a certain hour

For binary response models, the response of a sampling unit can take a specified value or not (for example, attended graduate school or not). Suppose $x$ is a row vector of explanatory variables and $\pi$ is the response probability to be modeled. The linear logistic model has the form

$$ \text{logit}(\pi) \equiv \log \left( \frac{\pi}{1 - \pi} \right) = \alpha + x\beta $$

where $\alpha$ is the intercept parameter and $\beta$ is the vector of slope parameters.

The logistic model shares a common feature with the more general class of generalized linear models, namely, that a function $g = g(\mu)$ of the expected value, $\mu$, of the response variable is assumed to be linearly related to the explanatory variables. Since $\mu$ implicitly depends on the stochastic behavior of the response, and since the explanatory variables are assumed to be fixed, the function $g$ provides the link between the random (stochastic) component and the systematic (deterministic) component of the response variable. For this reason, Nelder and Wedderburn (1972) refer to $g(\cdot)$ as a link function. One advantage of the logit function over other link functions is that differences on the logistic scale are interpretable regardless of whether the data are sampled prospectively or retrospectively (McCullagh and Nelder 1989, Chapter 4).

Other link functions that are widely used in practice are the probit function and the complementary log-log function. The SURVEYLOGISTIC procedure enables you to choose one of these link functions, resulting in fitting a broad class of binary response models of the form

$$ g(\pi) = \alpha + x\beta $$
For ordinal response models, the response $Y$ of an individual or an experimental unit may be restricted to one of a usually small number of ordinal values, denoted for convenience by $1, \ldots, D, D + 1$ ($D \geq 1$). For example, the pain severity can be classified into three response categories as $1$=mild, $2$=moderate, and $3$=severe. The SURVEYLOGISTIC procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$g(\Pr(Y \leq d \mid x)) = \alpha_d + x\beta, \quad 1 \leq d \leq D$$

where $\alpha_1, \ldots, \alpha_k$ are $k$ intercept parameters and $\beta$ is the vector of slope parameters. This model has been considered by many researchers. Aitchison and Silvey (1957) and Ashford (1959) employ a probit scale and provide a maximum likelihood analysis; Walker and Duncan (1967) and Cox and Snell (1989) discuss the use of the log-odds scale. For the log-odds scale, the cumulative logit model is often referred to as the proportional odds model.

For nominal response logistic models, where the $D + 1$ possible responses have no natural ordering, the logit model can also be extended to a generalized logit model, which has the form

$$\log \left( \frac{\Pr(Y = i \mid x)}{\Pr(Y = D + 1 \mid x)} \right) = \alpha_i + \beta_i'x, \quad i = 1, \ldots, D$$

where the $\alpha_1, \ldots, \alpha_D$ are $D$ intercept parameters, and the $\beta_1, \ldots, \beta_D$ are $D$ vectors of parameters. These models were introduced by McFadden (1974) as the discrete choice model, and they are also known as multinomial models.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data by the method of maximum likelihood. For statistical inferences, PROC SURVEYLOGISTIC incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The maximum likelihood estimation is carried out with either the Fisher-scoring algorithm or the Newton-Raphson algorithm. You can specify starting values for the parameter estimates. The logit link function in the ordinal logistic regression models can be replaced by the probit function or the complementary log-log function.

Odds ratio estimates are displayed along with parameter estimates. You can also specify the change in the explanatory variables for which odds ratio estimates are desired. Variances of the regression parameters and odds ratios are computed using the Taylor expansion approximation; see Binder (1983).

The SURVEYLOGISTIC procedure enables you to specify categorical variables (also known as CLASS variables) as explanatory variables. It also enables you to specify interaction terms in the same way as in the LOGISTIC procedure.

Like many procedures in SAS/STAT software that allow the specification of CLASS variables, the SURVEYLOGISTIC procedure provides a CONTRAST statement.
for specifying customized hypothesis tests concerning the model parameters. The CONTRAST statement also provides estimation of individual rows of contrasts, which is particularly useful for obtaining odds ratio estimates for various levels of the CLASS variables.

**Getting Started**

The SURVEYLOGISTIC procedure is similar to the LOGISTIC procedure and other regression procedures in the SAS System. Please refer to Chapter 42, “The LOGISTIC Procedure,” for general information about how to perform logistic regression using SAS. PROC SURVEYLOGISTIC is designed to handle sample survey data, and thus it incorporates the sampling design information into the analysis.

The following example illustrates how to use PROC SURVEYLOGISTIC to perform logistic regression for sample survey data.

In the customer satisfaction survey example in the “Getting Started” section on page 4422 of Chapter 72, “The SURVEYSELECT Procedure,” an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company’s current subscribers from four states: Alabama (AL), Florida (FL), Georgia (GA), and South Carolina (SC). The company plans to select a sample of customers from this population, interview the selected customers and ask their opinions on customer service, and then make inferences about the entire population of subscribers from the sample data. A stratified sample is selected using the probability proportional to size (PPS) method. The sample design divides the customers into strata depending on their types (‘Old’ or ‘New’) of their states (AL, FL, GA, SC). There are eight strata in all. Within each stratum, customers are selected and interviewed using the PPS with replacement method, where the size variable is Usage. The stratified PPS sample contains 192 customers. The data are stored in the SAS data set `SampleStrata`. Figure 69.1 displays the first 10 observations of this data set.

**Figure 69.1.** Stratified PPS Sample (First 10 Observations)

In the SAS data set `SampleSRS`, the variable `CustomerID` uniquely identifies each customer.
customer. The variable State contains the state of the customer’s address. The variable Type equals ‘Old’ if the customer has subscribed to the service for more than one year; otherwise, the variable Type equals ‘New’. The variable Usage contains the customer’s average monthly service usage, in hours. The variable Rating contains the customer’s responses to the survey. The sample design uses an unequal probability sampling method, with the sampling weights stored in the variable SamplingWeight.

The following SAS statements fit a cumulative logistic model between the satisfaction levels and the Internet usage using the stratified PPS sample.

```sas
title 'Customer Satisfaction Survey';
proc surveylogistic data=SampleStrata;
   strata state type/list;
   model Rating (order=internal) = Usage;
   weight SamplingWeight;
run;
```

The PROC statement invokes the SURVEYLOGISTIC procedure. The STRATA statement specifies the stratification variables State and Type that are used in the sample design. The LIST option requests a summary of the stratification. In the MODEL statement, Rating is the response variable and Usage is the explanatory variable. The ORDER=internal is used for the response variable Rating to ask the procedure to order the response levels using the internal numerical value (1-5) instead of the formatted character value. The WEIGHT statement specifies the variable SamplingWeight that contains the sampling weights.

The results of this analysis are shown in the following tables.

<table>

**Figure 69.2.** Stratified PPS Sample, Model Information

PROC SURVEYLOGISTIC first lists the following model fitting information and sample design information in **Figure 69.2**:

- The link function is the logit of the cumulative of the lower response categories.
• The Fisher Scoring optimization technique is used to obtain the maximum likelihood estimates for the regression coefficients.
• The response variable is Rating, which has five response levels.
• The stratification variables are State and Type.
• There are eight strata in the sample.
• The weight variable is SamplingWeight.
• The variance adjustment method used for the regression coefficients is the default degrees of freedom adjustment.

\[
\begin{array}{l}
\text{Customer Satisfaction Survey} \\
\text{Number of Observations Read} & 192 \\
\text{Number of Observations Used} & 192 \\
\text{Sum of Weights Read} & 13262.74 \\
\text{Sum of Weights Used} & 13262.74 \\
\end{array}
\]

\textbf{Figure 69.3.} Stratified PPS Sample, Number of Observations

Figure 69.3 lists the number of observations in the data set and the number of observations used in the analysis. Since no missing value presents in this example, observations in the entire data set are used in the analysis. The sums of weights are also reported in this table.

\[
\begin{array}{l}
\text{Customer Satisfaction Survey} \\
\text{Response Profile} \\
\hline
\text{Ordered Value} & \text{Rating} & \text{Total Frequency} & \text{Total Weight} \\
1 & \text{Extremely Unsatisfied} & 52 & 2067.1092 \\
2 & \text{Unsatisfied} & 47 & 2140.7127 \\
3 & \text{Neutral} & 47 & 3649.4869 \\
4 & \text{Satisfied} & 38 & 2533.5379 \\
5 & \text{Extremely Satisfied} & 8 & 2863.8888 \\
\text{Probabilities modeled are cumulated over the lower Ordered Values.}
\end{array}
\]

\textbf{Figure 69.4.} Stratified PPS Sample, Response Profile

The “Response Profile” table in Figure 69.4 lists the five response levels, their ordered values, and their total frequencies and total weights for each category. Due to the ORDER=internal option for the response variable Rating, the category “Extremely Unsatisfied” has the Ordered Value 1, the category “Unsatisfied” has the Ordered Value 2, and so on.
Figure 69.5. Stratified PPS Sample, Stratification Summary

Figure 69.5 displays the output of the stratification summary. There are a total of eight strata, and each stratum is defined by the customer types within each state. The table also shows the number of customers within each stratum.

Figure 69.6. Stratified PPS Sample, Testing the Proportional Odds Assumption

Figure 69.6 shows the chi-square test for testing the proportional odds assumption. The test is highly significant, which indicates that the cumulative logit model may not adequately fit the data.

Figure 69.7. Stratified PPS Sample, Model Fitting Information
Figure 69.7 shows the iteration algorithm converged to obtain the MLE for this example. The “Model Fit Statistics” table contains the Akaike Information Criterion (AIC), the Schwarz Criterion (SC), and the negative of twice the log likelihood (-2 Log L) for the intercept-only model and the fitted model. AIC and SC can be used to compare different models, and the ones with smaller values are preferred.

CLASS variable <(v-options)> <variable <(v-options)>... >
   < / v-options >;
CLUSTER variables;
CONTRAST 'label' effect values <,... effect values>< / options >;
FREQ variable;
MODEL events/trials = < effects >< / options >;
MODEL variable < (variable-options) > = < effects >< / options >;
STRATA variables < / options >;
< label: > TEST equation1 < ,... , < equationk >> < /option >;
UNITS independent1 = list1 < ... independentk = listk >> < /option >;
WEIGHT variable < / option >;
```

The PROC SURVEYLOGISTIC and MODEL statements are required. The CLASS, CLUSTER, STRATA, and CONTRAST statements can appear multiple times. You should only use one MODEL statement and one WEIGHT statement. The CLASS statement (if used) must precede the MODEL statement, and the CONTRAST statement (if used) must follow the MODEL statement.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC SURVEYLOGISTIC statement. The remaining statements are covered in alphabetical order.

**PROC SURVEYLOGISTIC Statement**

```
PROC SURVEYLOGISTIC < options >;
```

The PROC SURVEYLOGISTIC statement invokes the SURVEYLOGISTIC procedure and optionally identifies input data sets and controls the ordering of the response levels.

**ALPHA=** $\alpha$

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of $\alpha$ produces $100(1 - \alpha)\%$ confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

**DATA=** SAS-data-set

names the SAS data set containing the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.
**PROC SURVEYLOGISTIC Statement**

```
INEST= SAS-data-set
```

names the SAS data set that contains initial estimates for all the parameters in the model. BY-group processing is allowed in setting up the INEST= data set. See the section “INEST= Data Set” on page 4280 for more information.

**MISSING**

requests that the procedure treat missing values as a valid category for all categorical variables, which include classification variables in the model, strata variables, and cluster variables.

**NAMELEN=n**

specifies the length of effect names in tables and output data sets to be $n$ characters, where $n$ is a value between 20 and 200. The default length is 20 characters.

**NOSORT**

suppresses the internal sorting process to shorten the computation time if the data set is presorted by the STRATA and CLUSTER variables. By default, the procedure sorts the data by the STRATA variables if you use the STRATA statement; then the procedure sorts the data by the CLUSTER variables within strata. If your data are already stored by the order of STRATA and CLUSTER variables, then you can specify this option to omit this sorting process to reduce the usage of computing resources, especially when your data set is very large. However, if you specify this NOSORT option while your data is not presorted by STRATA and CLUSTER variables, then any changes in these variables creates a new stratum or cluster.

```
RATE=value | SAS-data-set
R=value | SAS-data-set
```

specifies the sampling rate as a nonnegative value, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction (fpc) for variance estimation when the sample design is without replacement. If your sample design has multiple stages, you should specify the first-stage sampling rate, which is the ratio of the number of primary sampling units (PSUs) selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative value for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “Specification of Population Totals and Sampling Rates” on page 4280 for more details.

The value in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify value as a number between 0 and 1. Or you can specify value in percentage form as a number between 1 and 100, and PROC SURVEYLOGISTIC will convert that number to a proportion. The procedure treats the value 1 as 100%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.
TOTAL= value | SAS-data-set
N= value | SAS-data-set

specifies the total number of primary sampling units (PSUs) in the study population as a positive value, or names an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive value for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “Specification of Population Totals and Sampling Rates” on page 4280 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

BY Statement

BY variables;

You can specify a BY statement with PROC SURVEYLOGISTIC to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty.

When a BY statement appears, the procedure expects the input data sets to be sorted in the order of the BY variables. The variables are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Use the BY statement options NOTSORTED or DESCENDING in the BY statement. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.
**CLASS Statement**

```
CLASS variable <(v-options)> <variable <(v-options)>... > < / v-options >;
```

The CLASS statement names the classification variables to be used in the analysis. The CLASS statement must precede the MODEL statement. You can specify various `v-options` for each variable by enclosing them in parentheses after the variable name. You can also specify global `v-options` for the CLASS statement by placing them after a slash (/). Global `v-options` are applied to all the variables specified in the CLASS statement. However, individual CLASS variable `v-options` override the global `v-options`.

**CPREFIX= n**

specifies that, at most, the first `n` characters of a CLASS variable name be used in creating names for the corresponding dummy variables. The default is \( 32 - \min(32, \max(2, f)) \), where `f` is the formatted length of the CLASS variable.

**DESCENDING DESC**

reverses the sorting order of the classification variable.

**LPREFIX= n**

specifies that, at most, the first `n` characters of a CLASS variable label be used in creating labels for the corresponding dummy variables.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sorting order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option may be useful when you use the CONTRAST statement. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC SURVEYLOGISTIC interprets values of the ORDER= option.

<table>
<thead>
<tr>
<th>Value of ORDER=</th>
<th>Levels Sorted By</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>order of appearance in the input data set</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value</td>
</tr>
<tr>
<td>FREQ</td>
<td>descending frequency count; levels with the most observations come first in the order</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>unformatted value</td>
</tr>
</tbody>
</table>

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter
on the SORT procedure in the *SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PARAM=** *keyword*

specifies the parameterization method for the classification variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=EFFECT. If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used.

- **EFFECT** specifies effect coding
- **GLM** specifies less-than-full-rank, reference cell coding; this option can only be used as a global option
- **ORDINAL** specifies the cumulative parameterization for an ordinal CLASS variable.
- **POLYNOMIAL** specifies polynomial coding
- **POLY** specifies reference cell coding
- **REFERENCE** specifies index parameterization
- **REF** orthogonalizes PARAM=EFFECT
- **ORTHEFFECT** orthogonalizes PARAM=ORDINAL
- **ORTHORDER** orthogonalizes PARAM=POLYNOMIAL
- **ORTHPOLY** orthogonalizes PARAM=REFERENCE
- **ORTHREF** orthogonalizes PARAM=REFERENCE

The EFFECT, POLYNOMIAL, REFERENCE, ORDINAL, and their orthogonal parameterizations are full rank. The REF= option in the CLASS statement determines the reference level for the EFFECT, REFERENCE, and their orthogonal parameterizations.

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization.

**REF=** *'level' | keyword*

specifies the reference level for PARAM=EFFECT or PARAM=REFERENCE. For an individual (but not a global) variable REF= option, you can specify the level of the variable to use as the reference level. For a global or individual variable REF= option, you can use one of the following keywords. The default is REF=LAST.

- **FIRST** designates the first ordered level as reference
- **LAST** designates the last ordered level as reference
**CONTRAST Statement**

**CLUSTER Statement**

```
CLUSTER | CLUSTERS variables;
```

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement. See the section “Primary Sampling Units (PSUs)” on page 4281 for more information.

The CLUSTER variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses all variables from all CLUSTER statements to create clusters.

**CONTRAST Statement**

```
CONTRAST 'label' row-description <,..., row-description> < / options >;
```

where a row-description is: `effect values <,..., effect values>`

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC LOGISTIC and PROC GLM, depending on the coding schemes used with any classification variables involved.

The CONTRAST statement enables you to specify a matrix, \(L\), for testing the hypothesis \(L\theta = 0\), where \(\theta\) is the parameter vector. You must be familiar with the details of the model parameterization that PROC SURVEYLOGISTIC uses (for more information, see the PARAM= option in the section “CLASS Statement” on page 4253). Optionally, the CONTRAST statement enables you to estimate each row, \(l_i\theta\), of \(L\theta\) and test the hypothesis \(l_i'\theta = 0\). Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The following parameters are specified in the CONTRAST statement:

- `label` identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.
effect identifies an effect that appears in the MODEL statement. The name INTERCEPT can be used as an effect when one or more intercepts are included in the model. You do not need to include all effects that are included in the MODEL statement.

values are constants that are elements of the $L$ matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of values to parameters.

The rows of $L$ are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple row-descriptions. For any of the full-rank parameterizations, if an effect is not specified in the CONTRAST statement, all of its coefficients in the $L$ matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by default or by specifying PARAM=EFFECT in the CLASS statement), all parameters are directly estimable (involve no other parameters). For example, suppose an effect coded CLASS variable $A$ has four levels. Then there are three parameters ($\alpha_1$, $\alpha_2$, $\alpha_3$) representing the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of $A$, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form $L\theta = 0$, is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$
or, equivalently,

\[ \alpha_1 + \alpha_2 - 2\alpha_3 = 0 \]

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements are constructed similarly. For example,

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
                  A 0 1 0,
                  A 0 0 1;
```

When you use the less-than-full-rank parameterization (by specifying PARAM=GLM
in the CLASS statement), each row is checked for estimability. If PROC
SURVEYLOGISTIC finds a contrast to be nonestimable, it displays missing
values in corresponding rows in the results. PROC SURVEYLOGISTIC handles
missing level combinations of classification variables in the same manner as
PROC LOGISTIC. Parameters corresponding to missing level combinations are not
included in the model. This convention can affect the way in which you specify the
\( L \) matrix in your CONTRAST statement. If the elements of \( L \) are not specified for
an effect that contains a specified effect, then the elements of the specified effect are
distributed over the levels of the higher-order effect just as the LOGISTIC procedure
does for its CONTRAST and ESTIMATE statements. For example, suppose that
the model contains effects A and B and their interaction A*B. If you specify a
CONTRAST statement involving A alone, the \( L \) matrix contains nonzero terms for
both A and A*B, since A*B contains A.

The degrees of freedom is the number of linearly independent constraints implied by
the CONTRAST statement, that is, the rank of \( L \).

You can specify the following options after a slash (/).

\textbf{ALPHA=\( \alpha \)}

sets the confidence level for confidence limits. The value of the ALPHA= option
must be between 0 and 1, and the default value is 0.05. A confidence level of \( \alpha \)
produces \( 100(1 - \alpha)\% \) confidence limits. The default of ALPHA=0.05 produces
95\% confidence limits.

\textbf{E}

requests that the \( L \) matrix be displayed.
ESTIMATE=keyword
requests that each individual contrast (that is, each row, \( l_i^\prime \beta \), of \( L\beta \) or exponentiated contrast \( (e^{l_i^\prime \beta}) \) be estimated and tested. PROC SURVEYLOGISTIC displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast \( (e^{l_i^\prime \beta}) \), or both, by specifying one of the following keywords:

- PARM specifies that the contrast itself be estimated
- EXP specifies that the exponentiated contrast be estimated
- BOTH specifies that both the contrast and the exponentiated contrast be estimated

SINGULAR = number
tunes the estimability check. This option is ignored when the full-rank parameterization is used. If \( v \) is a vector, define \( \text{ABS}(v) \) to be the largest absolute value of the elements of \( v \). For a row vector \( l^\prime \) of the contrast matrix \( L \), define \( c \) to be equal to \( \text{ABS}(l) \) if \( \text{ABS}(l) \) is greater than 0; otherwise, \( c \) equals 1. If \( \text{ABS}(l^\prime - l^\prime T) \) is greater than \( c * \text{number} \), then \( l \) is declared nonestimable. The \( T \) matrix is the Hermite form matrix \( I_0^{-1}I_0 \), where \( I_0^{-1} \) represents a generalized inverse of the information matrix \( I_0 \) of the null model. The value for \( \text{number} \) must be between 0 and 1; the default value is 1E-4.

FREQ Statement

FREQ variable ;

The \( \text{variable} \) in the FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC SURVEYLOGISTIC treats each observation as if it appears \( n \) times, where \( n \) is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1.

If you use the \( \text{events/trials} \) syntax in the MODEL statement, the FREQ statement is disallowed because the event and trial variables represent the frequencies in the data set.

MODEL Statement

MODEL events/trials= \( < \text{effects} > \) / \( \text{options} > \);
MODEL \( \text{variable} < (\text{variable_options}) > = \( < \text{effects} > \) / \( \text{options} > \);

The MODEL statement names the response variable and the explanatory effects, including covariates, main effects, interactions, and nested effects; see the section “Specification of Effects” on page 1784 of Chapter 32, “The GLM Procedure,”
for more information. If you omit the explanatory variables, the procedure fits an intercept-only model. Model options can be specified after a slash (/).

Two forms of the MODEL statement can be specified. The first form, referred to as single-trial syntax, is applicable to binary, ordinal, and nominal response data. The second form, referred to as events/trials syntax, is restricted to the case of binary response data. The single-trial syntax is used when each observation in the DATA= data set contains information on only a single trial, for instance, a single subject in an experiment. When each observation contains information on multiple binary-response trials, such as the counts of the number of subjects observed and the number responding, then events/trials syntax can be used.

In the events/trials syntax, you specify two variables that contain count data for a binomial experiment. These two variables are separated by a slash. The value of the first variable, events, is the number of positive responses (or events). The value of the second variable, trials, is the number of trials. The values of both events and (trials—events) must be nonnegative and the value of trials must be positive for the response to be valid.

In the single-trial syntax, you specify one variable (on the left side of the equal sign) as the response variable. This variable can be character or numeric. Options specific to the response variable can be specified immediately after the response variable with a pair of parentheses around them.

For both forms of the MODEL statement, explanatory effects follow the equal sign. Variables can be either continuous or classification variables. Classification variables can be character or numeric, and they must be declared in the CLASS statement. When an effect is a classification variable, the procedure enters a set of coded columns into the design matrix instead of directly entering a single column containing the values of the variable.

### Response Variable Options

You specify the following options by enclosing them in a pair of parentheses after the response variable.

**DESCENDING | DESC**

reverses the order of response categories. If both the DESCENDING and ORDER= options are specified, PROC SURVEYLOGISTIC orders the response categories according to the ORDER= option and then reverses that order. See the “Response Level Ordering” section on page 4269 for more detail.

**EVENT='category' | keyword**

specifies the event category for the binary response model. PROC SURVEYLOGISTIC models the probability of the event category. The EVENT= option has no effect when there are more than two response categories. You can specify the value (formatted if a format is applied) of the event category in quotes or you can specify one of the following keywords. The default is EVENT=FIRST.

- **FIRST** designates the first ordered category as the event
- **LAST** designates the last ordered category as the event
One of the most common sets of response levels is \{0,1\}, with 1 representing the event for which the probability is to be modeled. Consider the example where \( Y \) takes the values 1 and 0 for event and nonevent, respectively, and \text{Exposure} is the explanatory variable. To specify the value 1 as the event category, use the model statement

\[
\text{model } Y(\text{event}='1') = \text{Exposure};
\]

\textbf{ORDER= DATA | FORMATTED | FREQ | INTERNAL}

specifies the sorting order for the levels of the response variable. By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent.

When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows the interpretation of the ORDER= values.

<table>
<thead>
<tr>
<th>Value of ORDER=</th>
<th>Levels Sorted By</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>order of appearance in the input data set</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value</td>
</tr>
<tr>
<td>FREQ</td>
<td>descending frequency count; levels with the most observations come first in the order</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>unformatted value</td>
</tr>
</tbody>
</table>

For more information on sorting order, see the chapter on the SORT procedure in the \textit{SAS Procedures Guide} and the discussion of BY-group processing in \textit{SAS Language Reference: Concepts}.

\textbf{REFERENCE='category' | keyword}

\textbf{REF='category' | keyword}

specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each nonreference category is contrasted with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event category. You can specify the value (formatted if a format is applied) of the reference category in quotes or you can specify one of the following keywords. The default is REF=LAST.

\begin{itemize}
  \item \textbf{FIRST} designates the first ordered category as the reference
  \item \textbf{LAST} designates the last ordered category as the reference
\end{itemize}
Model Options

Model options can be specified after a slash (/). Table 69.1 summarizes the options available in the MODEL statement.

Table 69.1. Model Statement Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

</tbody>
</table>

The following list describes these options.

**ABSFCONV=** value

specifies the absolute function convergence criterion. Convergence requires a small change in the log-likelihood function in subsequent iterations,

$$|l^{(i)} - l^{(i-1)}| < value$$

where $l^{(i)}$ is the value of the log-likelihood function at iteration $i$. See the section “Convergence Criteria” on page 4277.
**ALPHA=α**

sets the level of significance $\alpha$ for $100(1 - \alpha)\%$ confidence intervals for regression parameters or odds ratios. The value $\alpha$ must be between 0 and 1. By default, $\alpha$ is equal to the value of the ALPHA= option in the PROC SURVEYLOGISTIC statement, or $\alpha = 0.05$ if the option is not specified. This option has no effect unless confidence limits for the parameters or odds ratios are requested.

**CLODDS**

requests confidence intervals for the odds ratios. Computation of these confidence intervals is based on individual Wald tests. The confidence coefficient can be specified with the ALPHA= option. See the “Wald Confidence Intervals for Parameters” section on page 4288 for more information.

**CLPARM**

requests confidence intervals for the parameters. Computation of these confidence intervals is based on the individual Wald tests. The confidence coefficient can be specified with the ALPHA= option. See the “Wald Confidence Intervals for Parameters” section on page 4288 for more information.

**CORRB**

displays the correlation matrix of the parameter estimates.

**COVB**

displays the covariance matrix of the parameter estimates.

**EXPB**

**EXPEST**

displays the exponentiated values ($e^{\hat{\theta}_i}$) of the parameter estimates $\hat{\theta}_i$ in the “Analysis of Maximum Likelihood Estimates” table for the logit model. These exponentiated values are the estimated odds ratios for the parameters corresponding to the continuous explanatory variables.

**FCONV=value**

specifies the relative function convergence criterion. Convergence requires a small relative change in the log-likelihood function in subsequent iterations,

$$\frac{|l(i) - l(i-1)|}{|l(i-1)| + 1E^{-6}} < value$$

where $l(i)$ is the value of the log-likelihood at iteration $i$. See the section “Convergence Criteria” on page 4277.

**GCONV=value**

specifies the relative gradient convergence criterion. Convergence requires that the normalized prediction function reduction is small,

$$\frac{g(i)^T I(i) g(i)}{|l(i)| + 1E^{-6}} < value$$

where $l(i)$ is the value of the log-likelihood function, $g(i)$ is the gradient vector, and $I(i)$ the (expected) information matrix. All of these functions are evaluated at iteration...
i. This is the default convergence criterion, and the default value is 1E−8. See the section “Convergence Criteria” on page 4277.

ITPRINT

displays the iteration history of the maximum-likelihood model fitting. The ITPRINT option also displays the last evaluation of the gradient vector and the final change in the −2 Log Likelihood.

LINK=keyword

L=keyword

specifies the link function linking the response probabilities to the linear predictors. You can specify one of the following keywords. The default is LINK=LOGIT.

CLOGLOG the complementary log-log function. PROC SURVEYLOGISTIC fits the binary complementary log-log model for binary response and fits the cumulative complementary log-log model when there are more than two response categories. Aliases: CCLOGLOG, CCLL, CUMCLOGLOG.

GLOGIT the generalized logit function. PROC SURVEYLOGISTIC fits the generalized logit model where each nonreference category is contrasted with the reference category. You can use the response variable option REF= to specify the reference category.

LOGIT the cumulative logit function. PROC SURVEYLOGISTIC fits the binary logit model when there are two response categories and fits the cumulative logit model when there are more than two response categories. Aliases: CLOGIT, CUMLOGIT.

PROBIT the inverse standard normal distribution function. PROC SURVEYLOGISTIC fits the binary probit model when there are two response categories and fits the cumulative probit model when there are more than two response categories. Aliases: NORMIT, CPROBIT, CUMPROMIT.

See the section “Link Functions and the Corresponding Distributions” on page 4273 for details.

MAXITER=n

specifies the maximum number of iterations to perform. By default, MAXITER=25. If convergence is not attained in n iterations, the displayed output created by the procedure contain results that are based on the last maximum likelihood iteration.

NOCHECK

disables the checking process to determine whether maximum likelihood estimates of the regression parameters exist. If you are sure that the estimates are finite, this option can reduce the execution time if the estimation takes more than eight iterations. For more information, see the “Existence of Maximum Likelihood Estimates” section on page 4277.
NODUMMYPRINT
NODESIGNPRINT
NODP
suppresses the “Class Level Information” table, which shows how the design matrix
columns for the CLASS variables are coded.
NOINT
suppresses the intercept for the binary response model or the first intercept for the
ordinal response model.
OFFSET=name
names the offset variable. The regression coefficient for this variable will be fixed
at 1.
PARMLABEL
displays the labels of the parameters in the “Analysis of Maximum Likelihood
Estimates” table.
RIDGING=ABSOLUTE | RELATIVE | NONE
specifies the technique used to improve the log-likelihood function when its value
in the current iteration is less than that in the previous iteration. If you spec-
ify the RIDGING=ABSOLUTE option, the diagonal elements of the negative
(expected) Hessian are inflated by adding the ridge value. If you specify the
RIDGING=RELATIVE option, the diagonal elements are inflated by a factor of
1 plus the ridge value. If you specify the RIDGING=NONE option, the crude
line search method of taking half a step is used instead of ridging. By default,
RIDGING=RELATIVE.
RSQUARE
requests a generalized $R^2$ measure for the fitted model. For more information, see
the “Generalized Coefficient of Determination” section on page 4280.
SINGULAR=value
specifies the tolerance for testing the singularity of the Hessian matrix (Newton-
Raphson algorithm) or the expected value of the Hessian matrix (Fisher-scoring al-
gorithm). The Hessian matrix is the matrix of second partial derivatives of the log
likelihood. The test requires that a pivot for sweeping this matrix be at least this
number times a norm of the matrix. Values of the SINGULAR= option must be
numeric. By default, SINGULAR=1E−12.
STB
displays the standardized estimates for the parameters for the continuous explana-
tory variables in the “Analysis of Maximum Likelihood Estimates” table. The stan-
dardized estimate of $\theta_i$ is given by $\hat{\theta}_i/(s/s_i)$, where $s_i$ is the total sample standard
deivation for the $i$th explanatory variable and

$$s = \begin{cases} 
\pi/\sqrt{3} & \text{Logistic} \\
1 & \text{Normal} \\
\pi/\sqrt{6} & \text{Extreme-value}
\end{cases}$$
For the intercept parameters and parameters associated with a CLASS variable, the standardized estimates are set to missing.

**TECHNIQUE=FISHER | NEWTON**

*TECH=FISHER | NEWTON*

specifies the optimization technique for estimating the regression parameters. NEWTON (or NR) is the Newton-Raphson algorithm and FISHER (or FS) is the Fisher-scoring algorithm. Both techniques yield the same estimates, but the estimated covariance matrices are slightly different except for the case when the LOGIT link is specified for binary response data. The default is TECHNIQUE=FISHER. See the section “Iterative Algorithms for Model-Fitting” on page 4275 for details.

**VADJUST=DF | MOREL | NONE < ( Morel-options ) >**

**VARADJ=DF | MOREL | NONE < ( Morel-options ) >**

**VARADJUST=DF | MOREL | NONE < ( Morel-options ) >**

specifies an adjustment to the variance estimation (on page 4286) for the regression coefficients.

By default, PROC SURVEYLOGISTIC uses the degrees of freedom adjustment VADJUST=DF.

You can specify the VADJUST=MOREL option for the variance adjustment proposed by Morel (1989).

If you do not wish to use any variance adjustment, you can specify the VADJUST=NONE option.

You can specify the following Morel-options within parentheses after the VADJUST=MOREL option.

**ADJBOUND=\( \phi \)**

sets the upper bound coefficient \( \phi \) in the variance adjustment. This upper bound must be positive. By default, the procedure use \( \phi = 0.5 \). See the section “Adjustments to the Variance Estimation” on page 4286 for more details on how this upper bound is used in the variance estimation.

**DEFFBOUND=\( \delta \)**

sets the lower bound of the estimated design effect in the variance adjustment. This lower bound must be positive. By default, the procedure use \( \delta = 1 \). See the section “Adjustments to the Variance Estimation” on page 4286 for more details on how this lower bound is used in the variance estimation.

**XCONV=value**

specifies the relative parameter convergence criterion. Convergence requires a small relative parameter change in subsequent iterations,

\[
\max_j |\delta_j^{(i)}| < value
\]
where

\[
\delta_{ij}^{(i)} = \begin{cases} 
\theta_{ij}^{(i)} - \theta_{ij}^{(i-1)} & \text{if } |\theta_{ij}^{(i-1)}| < 0.01 \\
\frac{\theta_{ij}^{(i)} - \theta_{ij}^{(i-1)}}{\theta_{ij}^{(i-1)}} & \text{otherwise}
\end{cases}
\]

and \(\theta_{ij}^{(i)}\) is the estimate of the \(j\)th parameter at iteration \(i\). See the section “Iterative Algorithms for Model-Fitting” on page 4275.

**STRATA Statement**

```
STRATA | STRATUM variables < / option > ;
```

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of levels of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specification of Population Totals and Sampling Rates” on page 4280 for more information.

The STRATA variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the SAS Procedures Guide.

You can specify the following option in the STRATA statement after a slash (/):

**LIST**

displays a “Stratum Information” table, which includes values of the STRATA variables and sampling rates for each stratum. This table also provides the number of observations and number of clusters for each stratum and analysis variable. See the section “Displayed Output” on page 4292 for more details.

**TEST Statement**

```
< label: > TEST equation1 < , . . . , < equationk >> < / option > ;
```

The TEST statement tests linear hypotheses about the regression coefficients. The Wald test is used to jointly test the null hypotheses \(H_0: L\theta = c\) specified in a single TEST statement. When \(c = 0\) you should specify a CONTRAST statement instead.

Each equation specifies a linear hypothesis (a row of the \(L\) matrix and the corresponding element of the \(c\) vector); multiple equations are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an equation is as follows:

```
term < ± term . . . > < = ± term < ± term . . . >
```

where \(term\) is a parameter of the model, or a constant, or a constant times a parameter. For a binary response model, the intercept parameter is named INTERCEPT;
for an ordinal response model, the intercept parameters are named INTERCEPT, INTERCEPT2, INTERCEPT3, and so on. When no equal sign appears, the expression is set to 0. The following code illustrates possible uses of the TEST statement:

```plaintext
proc surveylogistic;
  model y= a1 a2 a3 a4;
  test1: test intercept + .5 * a2 = 0;
  test2: test intercept + .5 * a2;
  test3: test a1=a2=a3;
  test4: test a1=a2, a2=a3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

You can specify the following option in the TEST statement after a slash(/).

**PRINT**

displays intermediate calculations in the testing of the null hypothesis $H_0: L\theta = c$. This includes $L\hat{V}(\hat{\theta})L'$ bordered by $(L\hat{\theta} - c)$ and $|L\hat{V}(\hat{\theta})L'|^{-1}$ bordered by $[L\hat{V}(\hat{\theta})L']^{-1}(L\hat{\theta} - c)$, where $\hat{\theta}$ is the maximum likelihood estimator of $\theta$ and $\hat{V}(\hat{\theta})$ is the estimated covariance matrix of $\hat{\theta}$.

For more information, see the “Testing Linear Hypotheses about the Regression Coefficients” section on page 4288.

---

**UNITS Statement**

**UNITS independent1 = list1 < ... independentk = listk > < /option > ;**

The UNITS statement enables you to specify units of change for the continuous explanatory variables so that customized odds ratios can be estimated. An estimate of the corresponding odds ratio is produced for each unit of change specified for an explanatory variable. The UNITS statement is ignored for CLASS variables. If the CLODDS option is specified in the MODEL statement, the corresponding confidence limits for the odds ratios are also displayed.

The term `independent` is the name of an explanatory variable and `list` represents a list of units of change, separated by spaces, that are of interest for that variable. Each unit of change in a list has one of the following forms:

- `number`
- `SD` or `-SD`
- `number * SD`

where `number` is any nonzero number, and `SD` is the sample standard deviation of the corresponding independent variable. For example, $X = -2$ requests an odds ratio that represents the change in the odds when the variable $X$ is decreased by two units.
Chapter 69. The SURVEYLOGISTIC Procedure

\[ X = 2 \times \text{SD} \] requests an estimate of the change in the odds when \( X \) is increased by two sample standard deviations.

You can specify the following option in the UNITS statement after a slash(/).

**DEFAULT=** *list*

gives a list of units of change for all explanatory variables that are not specified in the UNITS statement. Each unit of change can be in any of the forms described previously. If the **DEFAULT=** option is not specified, PROC SURVEYLOGISTIC does not produce customized odds ratio estimates for any explanatory variable that is not listed in the UNITS statement.

For more information, see the “Odds Ratio Estimation” section on page 4288.

<table>
<thead>
<tr>
<th>WEIGHT Statement</th>
</tr>
</thead>
</table>

**WEIGHT** *variable* < / *option* >;

The **WEIGHT** statement names the variable that contains the sampling weights. This variable must be numeric. If you do not specify a **WEIGHT** statement, PROC SURVEYLOGISTIC assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. If you specify more than one **WEIGHT** statement, the procedure uses only the first **WEIGHT** statement and ignores the rest.

**Details**

**Missing Values**

Any observation with missing values for the response, offset, or explanatory variables is excluded from the analysis. The estimated linear predictor, its standard error estimate, the fitted probabilities, and their confidence limits are not computed for any observation with missing offset or explanatory variable values.

An observation is also excluded if it has a missing value for any STRATA or CLUSTER variable, unless the **MISSING** option is used in the PROC SURVEYLOGISTIC statement.

Missing values in your survey data (such as nonresponse) can compromise the quality of your results. An observation without missing values is called a *complete respondent*, and an observation with missing values is called an *incomplete respondent*.

If the missing data are missing at random, then PROC SURVEYLOGISTIC produces unbiased results when it excludes observations with missing values. However, if the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then excluding nonrespondents from the analysis may result in biased estimates that do not accurately represent the survey population.

When the missing data are not missing at random, you should use imputation to replace missing values with acceptable values and use sampling weight adjustments.
Response Level Ordering to compensate for nonresponse before you use PROC SURVEYLOGISTIC. Refer to Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more information.

Model Specification

Response Level Ordering

Response level ordering is important because, by default, PROC SURVEYLOGISTIC models the probabilities of response levels with lower Ordered Value. Ordered Values, displayed in the “Response Profile” table, are assigned to response levels in ascending sorted order. That is, the lowest response level is assigned Ordered Value 1, the next lowest is assigned Ordered Value 2, and so on. For example, if your response variable $Y$ takes values in \{1, \ldots, D + 1\}, then the functions of the response probabilities modeled with the cumulative model are

$$\text{logit}(\Pr(Y \leq i | x)), i = 1, \ldots, D$$

and for the generalized logit model they are

$$\log \left( \frac{\Pr(Y = i | x)}{\Pr(Y = D + 1 | x)} \right), i = 1, \ldots, D$$

where the highest Ordered Value $Y = D + 1$ is the reference level. You can change these default functions by specifying the EVENT=, the REF=, the DESCENDING, or the ORDER= response variable options in the MODEL statement.

For binary response data with event and nonevent categories, the procedure models the function

$$\text{logit}(\pi) = \log \left( \frac{\pi}{1 - \pi} \right)$$

where $\pi$ is the probability of the response level assigned Ordered Value 1 in the “Response Profiles” table. Since

$$\text{logit}(\pi) = - \text{logit}(1 - \pi)$$

the effect of reversing the order of the two response levels is to change the signs of $\alpha$ and $\beta$ in the model $\text{logit}(\pi) = \alpha + \beta' x$.

If your event category has a higher Ordered Value than the nonevent category, the procedure models the nonevent probability. You can use response variable options to model the event probability. For example, suppose the binary response variable $Y$
Chapter 69. The SURVEYLOGISTIC Procedure
takes the values 1 and 0 for event and nonevent, respectively, and Exposure is the explanatory variable. By default, the procedure assigns Ordered Value 1 to response level \( Y=0 \), and Ordered Value 2 to response level \( Y=1 \). Therefore, the procedure models the probability of the nonevent (Ordered Value=1) category. To model the event probability, you can do the following:

- explicitly state which response level is to be modeled using the response variable option EVENT= in the MODEL statement,
  
  ```
  model Y(event='1') = Exposure;
  ```

- specify the response variable option DESCENDING in the MODEL statement,
  
  ```
  model Y(descending)=Exposure;
  ```

- specify the response variable option REF= in the MODEL statement as the nonevent category for the response variable. This option is most useful when you are fitting a generalized logit model.
  
  ```
  model Y(ref='0') = Exposure;
  ```

- assign a format to \( Y \) such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For this example, \( Y=1 \) is assigned formatted value ‘event’ and \( Y=0 \) is assigned formatted value ‘nonevent’. Since ORDER=FORMATTED by default, Ordered Value 1 is assigned to response level \( Y=1 \) so the procedure models the event.

  ```
  proc format;
  value Disease 1='event' 0='nonevent';
  run;
  proc surveylogistic;
  format Y Disease.;
  model Y=Exposure;
  run;
  ```

CLASS Variable Parameterization

Consider a model with one CLASS variable A with four levels, 1, 2, 5, and 7. Details of the possible choices for the PARAM= option follow.

EFFECT

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of −1. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Effect Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A1</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>−1</td>
</tr>
</tbody>
</table>
Parameter estimates of CLASS main effects using the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all four levels.

GLM

As in PROC GLM, four columns are created to indicate group membership. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>GLM Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A1 A2 A5 A7</td>
</tr>
<tr>
<td>1</td>
<td>1 0 0 0</td>
</tr>
<tr>
<td>2</td>
<td>0 1 0 0</td>
</tr>
<tr>
<td>5</td>
<td>0 0 1 0</td>
</tr>
<tr>
<td>7</td>
<td>0 0 0 1</td>
</tr>
</tbody>
</table>

Parameter estimates of CLASS main effects using the GLM coding scheme estimate the difference in the effects of each level compared to the last level.

ORDINAL

Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Ordinal Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A2 A5 A7</td>
</tr>
<tr>
<td>1</td>
<td>0 0 0</td>
</tr>
<tr>
<td>2</td>
<td>1 0 0</td>
</tr>
<tr>
<td>5</td>
<td>1 1 0</td>
</tr>
<tr>
<td>7</td>
<td>1 1 1</td>
</tr>
</tbody>
</table>

The first level of the effect is a control or baseline level. Parameter estimates of CLASS main effects using the ORDINAL coding scheme estimate the effect on the response as the ordinal factor is set to each succeeding level. When the parameters for an ordinal main effect have the same sign, the response effect is monotonic across the levels.

POLYNOMIAL

POLY

Three columns are created. The first represents the linear term \( x \), the second represents the quadratic term \( x^2 \), and the third represents the cubic term \( x^3 \), where \( x \) is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, ... according to their sorting order. The design matrix columns for A are as follows.
Polynomial Coding

<table>
<thead>
<tr>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>7</td>
</tr>
</tbody>
</table>

REFERENCE

REF       Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>7</td>
</tr>
</tbody>
</table>

Parameter estimates of CLASS main effects using the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

ORTHEFFECT The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>7</td>
</tr>
</tbody>
</table>

ORTHORDINAL

ORTHOTHERM The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.
### Orthogonal Ordinal Coding

**Design Matrix**

<table>
<thead>
<tr>
<th>A</th>
<th>AOORD1</th>
<th>AOORD2</th>

</tbody>
</table>

### Link Functions and the Corresponding Distributions

Four link functions are available in the SURVEYLOGISTIC procedure. The logit function is the default. To specify a different link function, use the **LINK=** option in the MODEL statement. The link functions and the corresponding distributions are as follows:

- The logit function

\[
g(\pi) = \log \left( \frac{\pi}{1 - \pi} \right)\]
is the inverse of the cumulative logistic distribution function, which is

\[ F(x) = \frac{1}{1 + e^{-x}} \]

- The probit (or normit) function

\[ g(\pi) = \Phi^{-1}(\pi) \]

is the inverse of the cumulative standard normal distribution function, which is

\[ F(x) = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{1}{2}z^2} dz \]

Traditionally, the probit function includes an additive constant 5, but throughout PROC SURVEYLOGISTIC, the terms probit and normit are used interchangeably, defined as \( g(p) \) above.

- The complementary log-log function

\[ g(\pi) = \log(-\log(1 - \pi)) \]

is the inverse of the cumulative extreme-value function (also called the Gompertz distribution), which is

\[ F(x) = 1 - e^{-e^x} \]

- The generalized logit function extends the binary logit link to a vector of levels \((\pi_1, \ldots, \pi_{k+1})\) by contrasting each level with a fixed level

\[ g(\pi_i) = \log\left(\frac{\pi_i}{\pi_{k+1}}\right) \quad i = 1, \ldots, k \]

The variances of the normal, logistic, and extreme-value distributions are not the same. Their respective means and variances are

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Mean</th>
<th>Variance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Logistic</td>
<td>0</td>
<td>(\pi^2/3)</td>
</tr>
<tr>
<td>Extreme-value</td>
<td>(-\gamma)</td>
<td>(\pi^2/6)</td>
</tr>
</tbody>
</table>

where \(\gamma\) is the Euler constant. In comparing parameter estimates using different link functions, you need to take into account the different scalings of the corresponding distributions and, for the complementary log-log function, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates using the logit link function should be about \(\pi/\sqrt{3} \approx 1.8\) larger than the estimates from the probit link function.
Model Fitting

Determining Observations for Likelihood Contributions

If you use events/trials syntax, each observation is split into two observations. One has the response value 1 with a frequency equal to the frequency of the original observation (which is 1 if the FREQ statement is not used) times the value of the events variable. The other observation has the response value 2 and a frequency equal to the frequency of the original observation times the value of (trials − events). These two observations have the same explanatory variable values and the same FREQ and WEIGHT values as the original observation.

For either single-trial or events/trials syntax, let $j$ index all observations. In other words, for single-trial syntax, $j$ indexes the actual observations. And, for events/trials syntax, $j$ indexes the observations after splitting (as described previously). If your data set has 30 observations and you use single-trial syntax, $j$ has values from 1 to 30; if you use events/trials syntax, $j$ has values from 1 to 60.

Suppose the response variable in a cumulative response model can take on the ordered values $1, \ldots, k, k+1$ where $k$ is an integer $\geq 1$. The likelihood for the $j$th observation with ordered response value $y_j$ and explanatory variables vector (row vectors) $x_j$ is given by

$$L_j = \left\{ \begin{array}{ll}
F(\alpha_1 + x_j\beta) & y_j = 1 \\
F(\alpha_i + x_j\beta) - F(\alpha_{i-1} + x_j\beta) & 1 < y_j = i \leq k \\
1 - F(\alpha_k + x_j\beta) & y_j = k + 1
\end{array} \right.$$  

where $F(.)$ is the logistic, normal, or extreme-value distribution function, $\alpha_1, \ldots, \alpha_k$ are ordered intercept parameters, and $\beta$ is the slope parameter vector.

For the generalized logit model, letting the $k + 1$st level be the reference level, the intercepts $\alpha_1, \ldots, \alpha_k$ are unordered and the slope vector $\beta_i$ varies with each logit. The likelihood for the $j$th observation with ordered response value $y_j$ and explanatory variables vector $x_j$ (row vectors) is given by

$$L_j = \Pr(Y = y_j|x_j) = \left\{ \begin{array}{ll}
e^{\alpha_i + x_j\beta_i} & 1 \leq y_j = i \leq k \\
1 + \sum_{i=1}^{k} e^{\alpha_i + x_j\beta_i} & y_j = k + 1
\end{array} \right.$$  

Iterative Algorithms for Model-Fitting

Two iterative maximum likelihood algorithms are available in PROC SURVEYLOGISTIC to obtain the maximum likelihood estimate $\hat{\theta}$ of the model parameter $\theta$. The default is the Fisher-scoring method, which is equivalent to fitting by iteratively reweighted least squares. The alternative algorithm is the
Newton-Raphson method. Both algorithms give the same parameter estimates; the covariance matrix of $\hat{\theta}$ is estimated in the section “Variance Estimation for Sample Survey Data” on page 4282. For a generalized logit model, only the Newton-Raphson technique is available. You can use the TECHNIQUE= option to select a fitting algorithm.

**Iteratively Reweighted Least-Squares Algorithm (Fisher Scoring)**

Let $Y$ be the response variable which takes values $1, \ldots, k, k+1$ ($k \geq 1$). Let $j$ index all observations and $Y_j$ be the value of response for the $j$th observation. Consider the multinomial variable $Z_j = (Z_{1j}, \ldots, Z_{kj})'$ such that

$$Z_{ij} = \begin{cases} 1 & \text{if } Y_j = i \\ 0 & \text{otherwise} \end{cases}$$

and $Z_{(k+1)j} = 1 - \sum_{i=1}^{k} Z_{ij}$. With $\pi_{ij}$ denoting the probability that the $j$th observation has response value $i$, the expected value of $Z_j$ is $\pi_j = (\pi_{1j}, \ldots, \pi_{kj})'$, and $\pi_{(k+1)j} = 1 - \sum_{i=1}^{k} \pi_{ij}$. The covariance matrix of $Z_j$ is $V_j$, which is the covariance matrix of a multinomial random variable for one trial with parameter vector $\pi_j$. Let $\theta$ be the vector of regression parameters; for example, $\theta = (\alpha_1, \ldots, \alpha_k, \beta')'$ for cumulative logit model. Let $D_j$ be the matrix of partial derivatives of $\pi_j$ with respect to $\theta$. The estimating equation for the regression parameters is

$$\sum_j D_j' W_j (Z_j - \pi_j) = 0$$

where $W_j = w_j f_j V_j^{-1}$, $w_j$ and $f_j$ are the WEIGHT and FREQ values of the $j$th observation.

With a starting value of $\theta^{(0)}$, the maximum likelihood estimate of $\theta$ is obtained iteratively as

$$\theta^{(i+1)} = \theta^{(i)} + \left( \sum_j D_j' W_j D_j \right)^{-1} \sum_j D_j' W_j (Z_j - \pi_j)$$

where $D_j$, $W_j$, and $\pi_j$ are evaluated at the $i$th iteration $\theta^{(i)}$. The expression after the plus sign is the step size. If the log-likelihood evaluated at $\theta^{(i+1)}$ is less than that evaluated at $\theta^{(i)}$, then $\theta^{(i+1)}$ is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained, that is, until $\theta^{(i+1)}$ is sufficiently close to $\theta^{(i)}$. Then the maximum likelihood estimate of $\theta$ is $\hat{\theta} = \theta^{(i+1)}$.

By default, starting values are zero for the slope parameters, and for the intercept parameters, starting values are the observed cumulative logits (that is, logits of the observed cumulative proportions of response). Alternatively, the starting values may be specified with the INEST= option.
Newton-Raphson Algorithm

Let
\[ g = \sum_j w_j f_j \frac{\partial l_j}{\partial \theta} \]
\[ H = \sum_j -w_j f_j \frac{\partial^2 l_j}{\partial \theta^2} \]
be the gradient vector and the Hessian matrix, where \( l_j = \log L_j \) is the log likelihood for the \( j \)th observation. With a starting value of \( \theta^{(0)} \), the maximum likelihood estimate \( \hat{\theta} \) of \( \theta \) is obtained iteratively until convergence is obtained:

\[ \theta^{(i+1)} = \theta^{(i)} + H^{-1} g \]

where \( H \) and \( g \) are evaluated at the \( i \)th iteration \( \theta^{(i)} \). If the log likelihood evaluated at \( \theta^{(i+1)} \) is less than that evaluated at \( \theta^{(i)} \), then \( \theta^{(i+1)} \) is recomputed by step-halving or ridging. The iterative scheme continues until convergence is obtained, that is, until \( \theta^{(i+1)} \) is sufficiently close to \( \theta^{(i)} \). Then the maximum likelihood estimate of \( \theta \) is \( \hat{\theta} = \theta^{(i+1)} \).

Convergence Criteria

Four convergence criteria are allowed, namely, ABSFCONV=, FCONV=, GCONV=, and XCONV=. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is GCONV=1E–8.

Existence of Maximum Likelihood Estimates

The likelihood equation for a logistic regression model does not always have a finite solution. Sometimes there is a nonunique maximum on the boundary of the parameter space, at infinity. The existence, finiteness, and uniqueness of maximum likelihood estimates for the logistic regression model depend on the patterns of data points in the observation space (Albert and Anderson 1984; Santner and Duffy 1986).

Consider a binary response model. Let \( Y_j \) be the response of the \( i \)th subject and let \( x_j \) be the vector of explanatory variables (including the constant 1 associated with the intercept). There are three mutually exclusive and exhaustive types of data configurations: complete separation, quasi-complete separation, and overlap.

Complete Separation

There is a complete separation of data points if there exists a vector \( b \) that correctly allocates all observations to their response groups; that is,

\[ \begin{cases} b' x_j > 0 & Y_j = 1 \\ b' x_j < 0 & Y_j = 2 \end{cases} \]
This configuration gives nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the log likelihood diminishes to zero, and the dispersion matrix becomes unbounded.

Quasi-Complete Separation

The data are not completely separable but there is a vector $b$ such that

$$\begin{cases} b'x_j \geq 0 & Y_j = 1 \\ b'x_j \leq 0 & Y_j = 2 \end{cases}$$

and equality holds for at least one subject in each response group. This configuration also yields nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the dispersion matrix becomes unbounded and the log likelihood diminishes to a nonzero constant.

Overlap

If neither complete nor quasi-complete separation exists in the sample points, there is an overlap of sample points. In this configuration, the maximum likelihood estimates exist and are unique.

Complete separation and quasi-complete separation are problems typically encountered with small data sets. Although complete separation can occur with any type of data, quasi-complete separation is not likely with truly continuous explanatory variables.

The SURVEYLOGIST procedure uses a simple empirical approach to recognize the data configurations that lead to infinite parameter estimates. The basis of this approach is that any convergence method of maximizing the log likelihood must yield a solution giving complete separation, if such a solution exists. In maximizing the log likelihood, there is no checking for complete or quasi-complete separation if convergence is attained in eight or fewer iterations. Subsequent to the eighth iteration, the probability of the observed response is computed for each observation. If the probability of the observed response is one for all observations, there is a complete separation of data points and the iteration process is stopped. If the complete separation of data has not been determined and an observation is identified to have an extremely large probability ($\geq 0.95$) of the observed response, there are two possible situations. First, there is overlap in the data set, and the observation is an atypical observation of its own group. The iterative process, if allowed to continue, will stop when a maximum is reached. Second, there is quasi-complete separation in the data set, and the asymptotic dispersion matrix is unbounded. If any of the diagonal elements of the dispersion matrix for the standardized observations vectors (all explanatory variables standardized to zero mean and unit variance) exceeds 5,000, quasi-complete separation is declared and the iterative process is stopped. If either complete separation or quasi-complete separation is detected, a warning message is displayed in the procedure output.
Checking for quasi-complete separation is less foolproof than checking for complete separation. The NOCHECK option in the MODEL statement turns off the process of checking for infinite parameter estimates. In cases of complete or quasi-complete separation, turning off the checking process typically results in the procedure failing to converge.

**Model Fitting Statistics**

Suppose the model contains $s$ explanatory effects. For the $j$th observation, let $\hat{\pi}_j$ be the estimated probability of the observed response. The three criteria displayed by the SURVEYLOGISTIC procedure are calculated as follows:

- **$-2$ Log Likelihood:**
  \[
  -2 \log L = -2 \sum_j w_j f_j \log(\hat{\pi}_j)
  \]
  where $w_j$ and $f_j$ are the weight and frequency values of the $j$th observation. For binary response models using events/trials syntax, this is equivalent to
  \[
  -2 \log L = -2 \sum_j w_j f_j \left\{ r_j \log(\hat{\pi}_j) + (n_j - r_j) \log(1 - \hat{\pi}_j) \right\}
  \]
  where $r_j$ is the number of events, $n_j$ is the number of trials, and $\hat{\pi}_j$ is the estimated event probability.

- **Akaike Information Criterion:**
  \[
  \text{AIC} = -2 \log L + 2p
  \]
  where $p$ is the number of parameters in the model. For cumulative response models, $p = k + s$ where $k$ is the total number of response levels minus one, and $s$ is the number of explanatory effects. For the generalized logit model, $p = k(s + 1)$.

- **Schwarz Criterion:**
  \[
  \text{SC} = -2 \log L + p \log(\sum_j f_j)
  \]
  where $p$ is as defined previously.

The $-2$ Log Likelihood statistic has a chi-square distribution under the null hypothesis (that all the explanatory effects in the model are zero) and the procedure produces a $p$-value for this statistic. The AIC and SC statistics give two different ways of adjusting the $-2$ Log Likelihood statistic for the number of terms in the model and the number of observations used.
**Generalized Coefficient of Determination**

Cox and Snell (1989, pp. 208–209) propose the following generalization of the coefficient of determination to a more general linear model:

\[
R^2 = 1 - \left( \frac{L(0)}{L(\hat{\theta})} \right)^{\frac{2}{n}}
\]

where \( L(0) \) is the likelihood of the intercept-only model, \( L(\hat{\theta}) \) is the likelihood of the specified model, and \( n \) is the sample size. The quantity \( R^2 \) achieves a maximum of less than 1 for discrete models, where the maximum is given by

\[
R^2_{\text{max}} = 1 - \{ L(0) \}^{\frac{2}{n}}
\]

Nagelkerke (1991) proposes the following adjusted coefficient, which can achieve a maximum value of 1:

\[
\tilde{R}^2 = \frac{R^2}{R^2_{\text{max}}}
\]

Properties and interpretation of \( R^2 \) and \( \tilde{R}^2 \) are provided in Nagelkerke (1991). In the “Testing Global Null Hypothesis: BETA=0” table, \( R^2 \) is labeled as “RSquare” and \( \tilde{R}^2 \) is labeled as “Max-rescaled RSquare.” Use the RSQUARE option to request \( R^2 \) and \( \tilde{R}^2 \).

**INEST= Data Set**

You can specify starting values for the iterative algorithm in the INEST= data set.

The INEST= data set contains one observation for each BY group. The INEST= data set must contain the intercept variables (named Intercept for binary response models and Intercept, Intercept2, Intercept3, and so forth, for ordinal response models) and all explanatory variables in the MODEL statement. If BY processing is used, the INEST= data set should also include the BY variables, and there must be one observation for each BY group. If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value ‘PARMS’ are used as starting values.

**Survey Design Information**

**Specification of Population Totals and Sampling Rates**

Variance estimates in survey samples involve a finite population correction (fpc) for sampling without replacement. For small sampling fractions or sampling with replacement, it is appropriate to ignore this correction (Cochran 1977; Kish 1965), and PROC SURVEYLOGISTIC does so by default. If your analysis requires an fpc, specify the sampling fraction using either the RATE= option or the TOTAL= option on the PROC SURVEYLOGISTIC statement. If you do not specify one of these options, the procedure does not use the fpc when computing variance estimates.
If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of primary sampling units (PSUs) in the sample to the total number of PSUs in the study population. If you are using the TOTAL= option for a multistage design, you should specify the total number of PSUs in the study population. See the section “Primary Sampling Units (PSUs)” on page 4281 for more details.

For a nonstratified sample design, or for a stratified sample design for which all the strata have the same sampling rate or population total, you should specify the rate or total as the value of the RATE=value option or the TOTAL=value option. If your sample design is stratified with different sampling rates or population totals in the strata, then you should use the RATE=SAS-data-set option or the TOTAL=SAS-data-set option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a secondary data set, as opposed to the primary data set that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement, as well as all the variables in the BY statement if any of these statements are specified. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=SAS-data-set option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. If you specify the RATE=SAS-data-set option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The value in the RATE= option or the values of _RATE_ in the secondary data set must be positive numbers. You can specify value as a number between 0 and 1; or you can specify value in percentage form as a number between 1 and 100, in which case PROC SURVEYLOGISTIC will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=value option, this value must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

**Primary Sampling Units (PSUs)**

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates the variance based on the variation among PSUs. Use the CLUSTER statement to identify the first-stage clusters in your design. PROC SURVEYLOGISTIC assumes that each cluster represents a PSU in the sample and that each observation is an element of a PSU. If you do not specify a CLUSTER statement, the procedure treats each observation as a PSU.
Variance Estimation for Sample Survey Data

Due to the variability of characteristics among items in the population, researchers apply scientific sample designs in the sample selection process to reduce the risk of a distorted view of the population, and they make inferences about the population based on the information from the sample survey data. In order to make statistically valid inferences for the population, they must incorporate the sample design in the data analysis.

The SURVEYLOGISTIC procedure fits linear logistic regression models for discrete response survey data using the maximum likelihood method. In the variance estimation, the procedure incorporates complex survey sample designs, including designs with stratification, clustering, and unequal weighting.

The procedure uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself. See Binder (1981, 1983), Roberts, Rao, and Kumar (1987), Skinner, Holt, and Smith (1989), Morel (1989), and Lehtonen and Pahkinen (1995) for papers that describe logistic regression for sample survey data. When there are clusters, or primary sampling units (PSUs), in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate. For $t$ tests of the estimates, the degrees of freedom equals the number of clusters minus the number of strata in the sample design. Statistical analyses, such as hypothesis tests and confident limits, will depend on these variance estimates.

Notation

Let $Y$ be the response variable with categories $1, 2, \ldots, D, D + 1$. The $p$ covariates are denoted by a $p$-dimension row vector $x$.

For a stratified clustered sample design, each observation is represented by a row vector,

$$(w_{hij}, y_{hij}', y_{hij(D+1)}, x_{hij})$$

where

- $h = 1, 2, \ldots, H$ is the stratum number with a total of $H$ strata
- $i = 1, 2, \ldots, n_h$ is the cluster number within stratum $h$, with a total of $n_h$ clusters
- $j = 1, 2, \ldots, m_{hi}$ is the unit number within cluster $i$ of stratum $h$, with a total of $m_{hi}$ units
- $w_{hij}$ denotes the sampling weight
- $y_{hij}$ is a $D$-dimensional column vector whose elements are indicator variables for the first $D$ categories for variable $Y$. If the response of the $j$th member of the $i$th cluster in stratum $h$ falls in category $d$, the $d$th row of the vector is one, and the remaining elements of the vector are zero, where $d = 1, 2, \ldots, D$
• $y_{hij(D+1)}$ is the indicator variable for the $(D + 1)$ category of variable $Y$
• $x_{hij}$ denotes the $k$-dimensional row vector of explanatory variables for the $j$th member of the $i$th cluster in stratum $h$. If there is an intercept, then $x_{hij1} \equiv 1$.
• $\tilde{n} = \sum_{h=1}^{H} n_h$ is the total number of clusters in the entire sample
• $n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi}$ is the total sample size

The following notations are also used in the following sections:

• $f_h$ denotes the sampling rate for stratum $h$
• $\pi_{hij}$ is the expected vector of the response variable

$$\pi_{hij} = E(y_{hij}|x_{hij}) = (\pi_{hij1}, \pi_{hij2}, \ldots, \pi_{hijD})'$$

$$\pi_{hij(D+1)} = E(y_{hij(D+1)}|x_{hij})$$

Note that $\pi_{hij(D+1)} = 1 - 1'\pi_{hij}$ where $1$ is a $D$-dimensional column vector whose elements are $1$.

**Likelihood Function**

Let $f(\cdot)$ be a link function such that

$$\pi = f(x, \theta)$$

where $\theta$ is a $p$-dimensional column vector for regression coefficients. The pseudo log likelihood is

$$l(\theta) = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \left( (\log(\pi_{hij}))'y_{hij} + \log(\pi_{hij(D+1)})y_{hij(D+1)} \right)$$

Denote the maximum likelihood estimator as $\hat{\theta}$, which is a solution to the estimating equations:

$$\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} D_{hij}' (\text{diag}(\pi_{hij}) - \pi_{hij} \pi_{hij}')^{-1} (y_{hij} - \pi_{hij}) = 0$$

where $D_{hij}$ is the matrix of partial derivatives of the link function $f$ with respect to $\theta$.

To obtain the maximum likelihood estimator $\hat{\theta}$, the procedure uses iterations with a starting value $\theta^{(0)}$ for $\theta$. See the section “Iterative Algorithms for Model-Fitting” on page 4275 for detail.
Generalized Logistic Model

Formulation of the generalized logit models for nominal response variables can be found in Agresti (1990). Without loss of generality, let the last category, \( D + 1 \), be the reference category for the response variable \( Y \). The link function for the generalized logistic model is defined as

\[
\pi_{hijd} = \frac{e^{x_{hijd}\beta_d}}{1 + \sum_{r=1}^{D} e^{x_{hijr}\beta_r}}
\]

and the model parameters are:

\[
\beta_d = (\beta_{d1}, \beta_{d2}, \ldots, \beta_{dk})'
\]
\[
\theta = (\beta_1', \beta_2', \ldots, \beta_D')'
\]

for \( d = 1, 2, \ldots, D \).

Cumulative Logit Model

Details of the cumulative logit model (or proportional odds model) can be found in McCullagh and Nelder (1989). Denote the cumulative sum of the expected proportions for the first \( d \) categories of variable \( Y \) by

\[
F_{hijd} = \sum_{r=1}^{d} \pi_{hijr}
\]

for \( d = 1, 2, \ldots, D \). Then the link function for the proportional odds model is

\[
\log \left( \frac{F_{hijd}}{1 - F_{hijd}} \right) = \alpha_d + x_{hij}\beta
\]

with the model parameters:

\[
\beta = (\beta_1, \beta_2, \ldots, \beta_k)'
\]
\[
\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_D)', \; \alpha_1 < \alpha_2 < \cdots < \alpha_D
\]
\[
\theta = (\alpha', \beta')'
\]

Complementary log-log Model

Use the notations in the previous section, the link function for the complementary log-log is

\[
\log(-\log(1 - F_{hijd})) = \alpha_d + x_{hij}\beta
\]

with the model parameters:

\[
\beta = (\beta_1, \beta_2, \ldots, \beta_k)'
\]
\[
\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_D)', \; \alpha_1 < \alpha_2 < \cdots < \alpha_D
\]
\[
\theta = (\alpha', \beta')'
\]
**Probit Model**

Another commonly used model for ordinal responses is the probit model with the link function

\[ F_{hijd} = \Phi(\alpha_d + x_{hij}\beta) \]

where

\[ \Phi(z_0) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{z_0} e^{-\frac{1}{2}z^2} dz \]

is the cumulative distribution function of the standard normal distribution. The model parameters are:

\[ \beta = (\beta_1, \beta_2, \ldots, \beta_k)' \]
\[ \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_D)', \; \alpha_1 < \alpha_2 < \cdots < \alpha_D \]
\[ \theta = (\alpha', \beta')' \]

**Estimated Variances**

Using Taylor approximation, the estimated covariance matrix of \( \hat{\theta} \) is

\[ \hat{V}(\hat{\theta}) = \hat{Q}^{-1} \hat{G} \hat{Q}^{-1} \]

where

\[ \hat{Q} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} \hat{D}_{hij} \left( \text{diag}(\hat{\pi}_{hij}) - \hat{\pi}_{hij} \hat{\pi}_{hij}' \right)^{-1} \hat{D}_{hij}' \]
\[ \hat{G} = \frac{n-1}{n-p} \sum_{h=1}^{H} n_h (1 - f_h) \sum_{i=1}^{n_h} \left( e_{hi.} - e_{h.\cdot} \right) \left( e_{hi.} - e_{h.\cdot} \right)' \]
\[ e_{hi.} = \sum_{j=1}^{m_{hi}} w_{hij} \hat{D}_{hij} \left( \text{diag}(\hat{\pi}_{hij}) - \hat{\pi}_{hij} \hat{\pi}_{hij}' \right)^{-1} (y_{hij} - \hat{\pi}_{hij}) \]
\[ e_{h.\cdot} = \frac{1}{n_h} \sum_{i=1}^{n_h} e_{hi.} \]

If you use the Newton-Raphson algorithm by using the `TECHNIQUE=NEWTON` option in the MODEL statement, the matrix \( Q \) is replaced by the negative (expected) Hessian matrix,

The matrices of partial derivatives \( \hat{D}_{hij} \) and the response probabilities \( \hat{\pi}_{hij} \) are evaluated at \( \hat{\theta} \).
Adjustments to the Variance Estimation

The factor \(\frac{n - 1}{n - p}\) in the computation of the matrix \(\hat{G}\) should reduce the small sample bias associated with using the estimated function to calculate deviations (Morel 1989; Hidiroglou, Fuller, and Hickman 1980). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which \(p\) parameter are estimated. By default, the procedure will use this adjustment in variance estimation. It is equivalent to specify the VADJUST=DF option in the MODEL statement. If you do not wish to use this multiplier in the variance estimation, you can specify the VADJUST=NONE option in the MODEL statement to suppress this factor.

In addition, you can specify the VADJUST=MOREL option to compute a further adjustment to the variance estimator for the regression coefficients \(\hat{\theta}\), introduced by Morel (1989):

\[
\tilde{\hat{V}}(\hat{\theta}) = \hat{Q}^{-1}\hat{G}\hat{Q}^{-1} + \kappa\lambda\hat{Q}^{-1}
\]

where for given nonnegative constants \(\delta\) and \(\phi\),

\[
\kappa = \max\left(\delta, \frac{1}{p} \text{tr}\left(\hat{Q}^{-1}\hat{G}\right)\right)
\]

\[
\lambda = \min\left(\phi, \frac{p}{n - p}\right)
\]

The adjustment \(\kappa\lambda\hat{Q}^{-1}\) will

- reduce the small sample bias reflected in inflated Type 1 error rates
- guarantee a positive definite estimated covariance matrix provided that \(\hat{Q}^{-1}\) exists
- be close to zero when the sample size becomes large

In this adjustment, \(\kappa\) is an estimate of the design effect, which has been bounded below by the positive constant \(\delta\). You can use DEFFBOUND=\(\delta\) in the VADJUST=MOREL option in the MODEL statement to specify this lower bound; by default, the procedure uses \(\delta = 1\). The factor \(\lambda\) converges to zero when the sample size becomes large, and \(\lambda\) has an upper bound \(\phi\). You can use ADJBOUND=\(\phi\) in the VADJUST=MOREL option in the MODEL statement to specify this upper bound; by default, the procedure uses \(\phi = 0.5\).
Hypothesis Testing and Estimation

Score Statistics and Tests

To understand the general form of the score statistics, let $g(\theta)$ be the vector of first partial derivatives of the log likelihood with respect to the parameter vector $\theta$, and let $g(\theta)$ be the matrix of second partial derivatives of the log likelihood with respect to $\theta$. That is, $g(\theta)$ is the gradient vector, and $H(\theta)$ is the Hessian matrix. Let $I(\theta)$ be either $-H(\theta)$ or the expected value of $-H(\theta)$. Consider a null hypothesis $H_0$. Let $\hat{\theta}_0$ be the MLE of $\theta$ under $H_0$. The chi-square score statistic for testing $H_0$ is defined by

$$g'(\hat{\theta}_0)I^{-1}(\hat{\theta}_0)g(\hat{\theta}_0)$$

and it has an asymptotic $\chi^2$ distribution with $r$ degrees of freedom under $H_0$, where $r$ is the number of restrictions imposed on $\theta$ by $H_0$.

Testing the Parallel Lines Assumption

For an ordinal response, PROC SURVEYLOGISTIC performs a test of the parallel lines assumption. In the displayed output, this test is labeled “Score Test for the Equal Slopes Assumption” when the LINK= option is NORMIT or CLOGLOG. When LINK=LOGIT, the test is labeled as “Score Test for the Proportional Odds Assumption” in the output. This section describes the methods used to calculate the test.

For this test the number of response levels, $D + 1$, is assumed to be strictly greater than 2. Let $Y$ be the response variable taking values $1, \ldots, D, D + 1$. Suppose there are $k$ explanatory variables. Consider the general cumulative model without making the parallel lines assumption

$$g(\Pr(Y \leq d \mid x)) = (1, x)\theta_d, \quad 1 \leq d \leq D$$

where $g(\cdot)$ is the link function, and $\theta_d = (\alpha_d, \beta_{d1}, \ldots, \beta_{dk})'$ is a vector of unknown parameters consisting of an intercept $\alpha_d$ and $k$ slope parameters $\beta_{k1}, \ldots, \beta_{kd}$. The parameter vector for this general cumulative model is

$$\theta = (\theta_1', \ldots, \theta_D')'$$

Under the null hypothesis of parallelism $H_0: \beta_{1i} = \beta_{2i} = \cdots = \beta_{Di}, 1 \leq i \leq k$, there is a single common slope parameter for each of the $s$ explanatory variables. Let $\beta_1, \ldots, \beta_k$ be the common slope parameters. Let $\hat{\alpha}_1, \ldots, \hat{\alpha}_D$ and $\hat{\beta}_1, \ldots, \hat{\beta}_D$ be the MLEs of the intercept parameters and the common slope parameters. Then, under $H_0$, the MLE of $\theta$ is

$$\hat{\theta}_0 = (\hat{\theta}_1', \ldots, \hat{\theta}_D')' \quad \text{with} \quad \hat{\theta}_d = (\hat{\alpha}_d, \hat{\beta}_1, \ldots, \hat{\beta}_k)' \quad 1 \leq d \leq D$$
and the chi-squared score statistic \( g'(\hat{\theta}_0)I^{-1}(\hat{\theta}_0)g(\hat{\theta}_0) \) has an asymptotic chi-square distribution with \( k(D-1) \) degrees of freedom. This tests the parallel lines assumption by testing the equality of separate slope parameters simultaneously for all explanatory variables.

**Wald Confidence Intervals for Parameters**

Wald confidence intervals are sometimes called the normal confidence intervals. They are based on the asymptotic normality of the parameter estimators. The 100(1 - \( \alpha \))% Wald confidence interval for \( \theta_j \) is given by

\[
\hat{\theta}_j \pm z_{1-\alpha/2}\hat{\sigma}_j
\]

where \( z_p \) is the 100\( p \)th percentile of the standard normal distribution, \( \hat{\theta}_j \) is the maximum likelihood estimate of \( \theta_j \), and \( \hat{\sigma}_j \) is the standard error estimate of \( \hat{\theta}_j \) in the section “Variance Estimation for Sample Survey Data” on page 4282.

**Testing Linear Hypotheses about the Regression Coefficients**

Linear hypotheses for \( \theta \) are expressed in matrix form as

\[
H_0: L\theta = c
\]

where \( L \) is a matrix of coefficients for the linear hypotheses, and \( c \) is a vector of constants. The vector of regression coefficients \( \theta \) includes slope parameters as well as intercept parameters. The Wald chi-square statistic for testing \( H_0 \) is computed as

\[
\chi^2_W = (\hat{L}\theta - c)'[L\hat{V}(\hat{\theta})L']^{-1}(\hat{L}\theta - c)
\]

where \( \hat{V}(\hat{\theta}) \) is the estimated covariance matrix in the section “Variance Estimation for Sample Survey Data” on page 4282. Under \( H_0 \), \( \chi^2_W \) has an asymptotic chi-square distribution with \( r \) degrees of freedom, where \( r \) is the rank of \( L \).

**Odds Ratio Estimation**

Consider a dichotomous response variable with outcomes event and nonevent. Consider a dichotomous risk factor variable \( X \) that takes the value 1 if the risk factor is present and 0 if the risk factor is absent. According to the logistic model, the log odds function, \( g(X) \), is given by

\[
g(X) \equiv \log \left( \frac{\Pr(\text{event} \mid X)}{\Pr(\text{nonevent} \mid X)} \right) = \beta_0 + \beta_1 X
\]

The odds ratio \( \psi \) is defined as the ratio of the odds for those with the risk factor \( (X = 1) \) to the odds for those without the risk factor \( (X = 0) \). The log of the odds ratio is given by

\[
\log(\psi) \equiv \log(\psi(X = 1, X = 0)) = g(X = 1) - g(X = 0) = \beta_1
\]
The parameter, \( \beta_1 \), associated with \( X \) represents the change in the log odds from \( X = 0 \) to \( X = 1 \). So, the odds ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The odds ratio indicates how the odds of an event change as you change \( X \) from 0 to 1. For instance, \( \psi = 2 \) means that the odds of an event when \( X = 1 \) are twice the odds of an event when \( X = 0 \).

Suppose the values of the dichotomous risk factor are coded as constants \( a \) and \( b \) instead of 0 and 1. The odds when \( X = a \) become \( \exp(\beta_0 + a \beta_1) \), and the odds when \( X = b \) become \( \exp(\beta_0 + b \beta_1) \). The odds ratio corresponding to an increase in \( X \) from \( a \) to \( b \) is

\[
\psi = \exp[(b - a) \beta_1] = [\exp(\beta_1)]^{b-a} \equiv [\exp(\beta_1)]^c
\]

Note that for any \( a \) and \( b \) such that \( c = b - a = 1 \), \( \psi = \exp(\beta_1) \). So the odds ratio can be interpreted as the change in the odds for any increase of one unit in the corresponding risk factor. However, the change in odds for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight may be too small to be considered important, while a change of 10 pounds may be more meaningful. The odds ratio for a change in \( X \) from \( a \) to \( b \) is estimated by raising the odds ratio estimate for a unit change in \( X \) to the power of \( c = b - a \) as shown previously.

For a polytomous risk factor, the computation of odds ratios depends on how the risk factor is parameterized. For illustration, suppose that \( \text{Race} \) is a risk factor with four categories: White, Black, Hispanic, and Other.

For the effect parameterization scheme (PARAM=EFFECT) with White as the reference group, the design variables for \( \text{Race} \) are as follows.

<table>
<thead>
<tr>
<th>Race</th>
<th>Design Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>( X_1 )</td>
</tr>
<tr>
<td>Black</td>
<td>1</td>
</tr>
<tr>
<td>Hispanic</td>
<td>0</td>
</tr>
<tr>
<td>Other</td>
<td>0</td>
</tr>
<tr>
<td>White</td>
<td>-1</td>
</tr>
</tbody>
</table>

The log odds for Black is

\[
g(\text{Black}) = \beta_0 + \beta_1 (X_1 = 1) + \beta_2 (X_2 = 0) + \beta_3 (X_3 = 0) \\
= \beta_0 + \beta_1
\]

The log odds for White is

\[
g(\text{White}) = \beta_0 + \beta_1 (X_1 = -1) + \beta_2 (X_2 = -1) + \beta_3 (X_3 = -1)) \\
= \beta_0 - \beta_1 - \beta_2 - \beta_3
\]
Therefore, the log odds ratio of Black versus White becomes

$$\log(\psi(\text{Black}, \text{White})) = g(\text{Black}) - g(\text{White}) = 2\beta_1 + \beta_2 + \beta_3$$

For the reference cell parameterization scheme (PARAM=REF) with White as the reference cell, the design variables for race are as follows.

<table>
<thead>
<tr>
<th>Race</th>
<th>Design Variables</th>
<th>$X_1$</th>
<th>$X_2$</th>
<th>$X_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black</td>
<td></td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Hispanic</td>
<td></td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Other</td>
<td></td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>White</td>
<td></td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The log odds ratio of Black versus White is given by

$$\log(\psi(\text{Black}, \text{White})) = g(\text{Black}) - g(\text{White}) = (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) - (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) = \beta_1$$

For the GLM parameterization scheme (PARAM=GLM), the design variables are as follows.

<table>
<thead>
<tr>
<th>Race</th>
<th>Design Variables</th>
<th>$X_1$</th>
<th>$X_2$</th>
<th>$X_3$</th>
<th>$X_4$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Black</td>
<td></td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Hispanic</td>
<td></td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Other</td>
<td></td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>White</td>
<td></td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

The log odds ratio of Black versus White is

$$\log(\psi(\text{Black}, \text{White})) = g(\text{Black}) - g(\text{White}) = (\beta_0 + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 0)) - (\beta_0 + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 1)) = \beta_1 - \beta_4$$
Consider the hypothetical example of heart disease among race in Hosmer and Lemeshow (2000, p. 51). The entries in the following contingency table represent counts.

<table>
<thead>
<tr>
<th>Disease Status</th>
<th>White</th>
<th>Black</th>
<th>Hispanic</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td>Present</td>
<td>5</td>
<td>20</td>
<td>15</td>
<td>10</td>
</tr>
<tr>
<td>Absent</td>
<td>20</td>
<td>10</td>
<td>10</td>
<td>10</td>
</tr>
</tbody>
</table>

The computation of odds ratio of Black versus White for various parameterization schemes is tabulated in the following table.

<table>
<thead>
<tr>
<th>Odds Ratio of Heart Disease Comparing Black to White</th>
<th>Parameter Estimates</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARAM</td>
<td>$\hat{\beta}_1$</td>
</tr>
<tr>
<td>EFFECT</td>
<td>0.7651</td>
</tr>
<tr>
<td>REF</td>
<td>2.0794</td>
</tr>
<tr>
<td>GLM</td>
<td>2.0794</td>
</tr>
</tbody>
</table>

Since the log odds ratio ($\log(\psi)$) is a linear function of the parameters, the Wald confidence interval for $\log(\psi)$ can be derived from the parameter estimates and the estimated covariance matrix. Confidence intervals for the odds ratios are obtained by exponentiating the corresponding confidence intervals for the log odd ratios. In the displayed output of PROC SURVEYLOGISTIC, the “Odds Ratio Estimates” table contains the odds ratio estimates and the corresponding 95% Wald confidence intervals computed using the covariance matrix in the section “Variance Estimation for Sample Survey Data” on page 4282. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

To customize odds ratios for specific units of change for a continuous risk factor, you can use the `UNITS` statement to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized odds ratios are given in a separate table. Let $(L_j, U_j)$ be a confidence interval for $\log(\psi)$. The corresponding lower and upper confidence limits for the customized odds ratio $\exp(c\beta_j)$ are $\exp(cL_j)$ and $\exp(cU_j)$, respectively (for $c > 0$), or $\exp(cU_j)$ and $\exp(cL_j)$, respectively (for $c < 0$). You use the `CLODDS=` option to request the confidence intervals for the odds ratios.

For a generalized logit model, odds ratios are computed similarly, except $D$ odds ratios are computed for each effect, corresponding to the $D$ logits in the model.
Rank Correlation of Observed Responses and Predicted Probabilities

The predicted mean score of an observation is the sum of the Ordered Values (shown in the Response Profile table) minus one, weighted by the corresponding predicted probabilities for that observation; that is, the predicted mean score = \( \sum_{d=1}^{D+1} (d - 1) \hat{\pi}_d \), where \( D + 1 \) is the number of response levels and \( \hat{\pi}_d \) is the predicted probability of the \( d \)th (ordered) response.

A pair of observations with different observed responses is said to be \textit{concordant} if the observation with the lower ordered response value has a lower predicted mean score than the observation with the higher ordered response value. If the observation with the lower ordered response value has a higher predicted mean score than the observation with the higher ordered response value, then the pair is \textit{discordant}. If the pair is neither concordant nor discordant, it is a \textit{tie}. Enumeration of the total numbers of concordant and discordant pairs is carried out by categorizing the predicted mean score into intervals of length \( D/500 \) and accumulating the corresponding frequencies of observations.

Let \( N \) be the sum of observation frequencies in the data. Suppose there is a total of \( t \) pairs with different responses, \( n_c \) of them are concordant, \( n_d \) of them are discordant, and \( t - n_c - n_d \) of them are tied. PROC SURVEYLOGISTIC computes the following four indices of rank correlation for assessing the predictive ability of a model:

\[
\begin{align*}
\theta &= (n_c + 0.5(t - n_c - n_d))/t \\
\text{Somers' } D &= (n_c - n_d)/t \\
\text{Goodman-Kruskal Gamma} &= (n_c - n_d)/(n_c + n_d) \\
\text{Kendall's Tau-}\alpha &= (n_c - n_d)/(0.5N(N - 1))
\end{align*}
\]

Note that \( \theta \) also gives an estimate of the area under the receiver operating characteristic (ROC) curve when the response is binary (Hanley and McNeil 1982).

For binary responses, the predicted mean score is equal to the predicted probability for Ordered Value 2. As such, the preceding definition of concordance is consistent with the definition used in previous releases for the binary response model.

Output

Displayed Output

The displayed output of the SURVEYLOGISTIC procedure includes the following:

- name of the input Data Set
- name and label of the Response Variable if the \textit{single-trial} syntax is used
- number of Response Levels
- name of the Events Variable if the \textit{events/trials} syntax is used
- name of the Trials Variable if the \textit{events/trials} syntax is used
- Number of Observations read from the input data set
- Number of Observations used in the analysis
- name of the Frequency Variable if the FREQ statement is specified
- Sum of Frequencies of all the observations read from the input data set
- Sum of Frequencies of all the observations used in the analysis
- name of the Weight Variable if the WEIGHT statement is specified
- Sum of Weights of all the observations read from the input data set
- Sum of Weights of all the observations used in the analysis
- name of the Offset Variable if the OFFSET= option is specified
- name(s) of the stratification variable(s) if the STRATA statement is specified
- total number of strata if the STRATA statement is specified
- name(s) of the cluster variable(s) if the CLUSTER statement is specified
- total number of clusters if the CLUSTER statement is specified
- Sum of Weights of all the observations used in the analysis
- Link Function
- variance adjustment method
- parameters used in the VADJUST=MOREL option if this option is specified
- “Response Profile” table, which gives, for each response level, the ordered value (an integer between one and the number of response levels, inclusive); the value of the response variable if the single-trial syntax is used or the values “EVENT” and “NO EVENT” if the events/trials syntax is used; the count or frequency; and the sum of weights if the WEIGHT statement is specified
- “Class Level Information” table, which gives the level and the design variables for each CLASS explanatory variable
- “Maximum Likelihood Iterative Phase” table, which gives the iteration number, the step size (in the scale of 1.0, .5, .25, and so on) or the ridge value, $-2 \log$ likelihood, and parameter estimates for each iteration. Also displayed are the last evaluation of the gradient vector and the last change in the $-2 \log$ likelihood. You need to use the ITPRINT option in the MODEL statement to obtain this table
- score test result for testing the parallel lines assumption, if an ordinal response model is fitted. If LINK=CLOGLOG or LINK=PROBIT, this test is labeled “Score Test for the Parallel Slopes Assumption.” The proportion odds assumption is a special case of the parallel lines assumption when LINK=LOGIT. In this case, the test is labeled “Score Test for the Proportional Odds Assumption”
- “Model Fit Statistics” and “Testing Global Null Hypothesis: BETA=0” tables, which give the various criteria ($-2 \log$ L, AIC, SC) based on the likelihood for fitting a model with intercepts only and for fitting a model with intercepts and explanatory variables. If you specify the NOINT option, these statistics are calculated without considering the intercept parameters. The third column of the table gives the chi-square statistics and $p$-values for the $-2 \log$ L statistic and for the Score statistic. These test the joint effect of the explanatory
variables included in the model. The Score criterion is always missing for the models identified by the first two columns of the table. Note also that the first two rows of the Chi-Square column are always missing, since tests cannot be performed for AIC and SC.

- generalized $R^2$ measures for the fitted model if you specify the RSQUARE option in the MODEL statement.

- “Type III Analysis of Effects” table if the model contains an effect involving a CLASS variable. This table gives the Wald Chi-square statistic, the degrees of freedom, and the $p$-value for each effect in the model.

- “Analysis of Maximum Likelihood Estimates” table, which includes:
  - maximum likelihood estimate of the parameter
  - estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
  - Wald chi-square statistic, computed by squaring the ratio of the parameter estimate divided by its standard error estimate
  - $p$-value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
  - standardized estimate for the slope parameter, given by $\hat{\beta}_i / (s/s_i)$, where $s_i$ is the total sample standard deviation for the $i$th explanatory variable and

$$ s = \begin{cases} \frac{\pi}{\sqrt{3}} & \text{Logistic} \\ 1 & \text{Normal} \\ \frac{\pi}{\sqrt{6}} & \text{Extreme-value} \end{cases} $$

You need to specify the STB option in the MODEL statement to obtain these estimates. Standardized estimates of the intercept parameters are set to missing.

- value of $(e^{\hat{\beta}_i})$ for each slope parameter $\beta_i$ if you specify the EXPB option in the MODEL statement. For continuous variables, this is equivalent to the estimated odds ratio for a 1 unit change.

- label of the variable (if space permits) if you specify the PARMLABEL option in the MODEL statement. Due to constraints on the line size, the variable label may be suppressed in order to display the table in one panel. Use the SAS system option LINESIZE= to specify a larger line size to accommodate variable labels. A shorter line size can break the table into two panels allowing labels to be displayed.

- “Odds Ratio Estimates” table, which contains the odds ratio estimates and the corresponding 95% Wald confidence intervals. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

- measures of association between predicted probabilities and observed responses, which include a breakdown of the number of pairs with different responses, and four rank correlation indexes: Somers’ $D$, Goodman-Kruskal Gamma, and Kendall’s Tau-$a$, and $c$. 
- confidence intervals for all the parameters if you use the CLPARM option in the MODEL statement
- confidence intervals for all the odds ratios if you use the CLODDS option in the MODEL statement
- “Analysis of Effects not in the Model” table, which gives the score chi-square statistic for testing the significance of each variable not in the model after adjusting for the variables already in the model, and the p-value of the chi-square statistic with respect to a chi-square distribution with one degree of freedom. You specify the DETAILS option in the MODEL statement to obtain this table.
- estimated covariance matrix of the parameter estimates if you use the COVB option in the MODEL statement
- estimated correlation matrix of the parameter estimates if you use the CORRB option in the MODEL statement
- “Linear Hypothesis Testing” table, which gives the result of the Wald test for each TEST statement (if specified)

**ODS Table Names**

PROC SURVEYLOGISTIC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**Table 69.2. ODS Tables Produced in PROC SURVEYLOGISTIC**

Examples

Example 69.1. Logistic Regression with Different Link Functions for Stratified Cluster Sampling

A market research firm conducts a survey among undergraduate students at a certain university to evaluate three new Web designs for a commercial Web site targeting undergraduate students at the university.

The sample design is a stratified sample where strata are students’ classes. Within each class, 300 students are randomly selected using simple random sampling without replacement. The total number of students in each class in the fall semester of 2001 is shown in the following table:

<table>
<thead>
<tr>
<th>Class</th>
<th>Enrollment</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - Freshman</td>
<td>3,734</td>
</tr>
<tr>
<td>2 - Sophomore</td>
<td>3,565</td>
</tr>
<tr>
<td>3 - Junior</td>
<td>3,903</td>
</tr>
<tr>
<td>4 - Senior</td>
<td>4,196</td>
</tr>
</tbody>
</table>
This total enrollment information is saved in the SAS data set `Enrollment` using the following SAS statements:

```sas
proc format;
  value Class 1='Freshman' 2='Sophomore' 3='Junior' 4='Senior';
run;

data Enrollment;
  format Class Class.;
  input Class _TOTAL_;
datalines;
  1 3734
  2 3565
  3 3903
  4 4196
;
```

In the data set `Enrollment`, the variable `_TOTAL_` contains the enrollment figures for all classes. They are also the population size for each stratum in this example.

Each student selected in the sample evaluates one randomly selected Web design using the following scale:

<table>
<thead>
<tr>
<th>Rating</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>dislike very much</td>
</tr>
<tr>
<td>2</td>
<td>dislike</td>
</tr>
<tr>
<td>3</td>
<td>neutral</td>
</tr>
<tr>
<td>4</td>
<td>like</td>
</tr>
<tr>
<td>5</td>
<td>like very much</td>
</tr>
</tbody>
</table>

The survey results are collected and shown in the following table, with the three different Web designs coded as A, B, and C.

<table>
<thead>
<tr>
<th>Evaluation of New Web Designs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strata</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Freshman</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>

<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Junior</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Senior</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
The survey results are stored in a SAS data set WebSurvey using the following SAS statements.

```sas
proc format;
   value Design 1='A' 2='B' 3='C';
   value Rating 1='dislike very much'
                2='dislike'
                3='neutral'
                4='like'
                5='like very much';
run;

data WebSurvey;
   format Class Class. Design Design. Rating Rating. ;
   do Class=1 to 4;
      do Design=1 to 3;
         do Rating=1 to 5;
            input Count @@;
            output;
         end;
      end;
   end;
datalines;
  10 34 35 16 15  8 21 23 26 22  5 10 24 30 21
  1 14 25 23 37 11 14 20 34 21 16 19 30 23 12
 19 12 26 18 25 11 14 24 33 18 10 18 32 23 17
  8 15 35 30 12 15 22 34  9 20  2 34 30 18 16
;
data WebSurvey; set WebSurvey;
   if Class=1 then Weight=3734/300;
   if Class=2 then Weight=3565/300;
   if Class=3 then Weight=3903/300;
   if Class=4 then Weight=4196/300;
```

The data set WebSurvey contains the variables Class, Design, Rating, Count, and Weight. The variable class is the stratum variable, with four strata: freshman, sophomore, junior, and senior. The variable Design specifies the three new Web designs: A, B, and C. The variable Rating contains students’ evaluations for the new Web designs. The variable counts gives the frequency with which each Web design received each rating within each stratum. The variable weight contains the sampling weights, which are the reciprocals of selection probabilities in this example.
Output 69.1.1. Web Design Survey Sample (First 20 Observation)

</tbody>
</table>

Output 69.1.1 shows the first 20 observations of the data set.

The following SAS statements perform the logistic regression.

```sas
proc surveylogistic data=WebSurvey total=Enrollment;
    stratum Class;
    freq Count;
    class Design;
    model Rating (order=internal) = design ;
    weight Weight;
run;
```

The PROC statement invokes PROC SURVEYLOGISTIC. The TOTAL= option specifies the data set Enrollment, which contains the population totals in the strata. The population totals are used to calculate the finite population correction factor in the variance estimates. The response variable Rating is in the ordinal scale. A cumulative logit model is used to investigate the responses to the Web designs. In the MODEL statement, rating is the response variable, and Design is the effect in the regression model. The ORDER=INTERNAL option is used for the response variable Rating to sort the ordinal response levels of Rating by its internal (numerical) values rather than by the formatted values (e.g., “like very much”). Because the sample design involves stratified simple random sampling, the STRATA statement is used to specify the stratification variable Class. The WEIGHT statement specifies the variable Weight for sampling weights.
Output 69.1.2.  Web Design Survey, Model Information

The SURVEYLOGISTIC Procedure

Response Profile

<table>
<thead>
<tr>
<th>Ordered Value</th>
<th>Rating</th>
<th>Total Frequency</th>
<th>Total Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>dislike very much</td>
<td>116</td>
<td>1489.0733</td>
</tr>
<tr>
<td>2</td>
<td>dislike</td>
<td>227</td>
<td>2933.0433</td>
</tr>
<tr>
<td>3</td>
<td>neutral</td>
<td>338</td>
<td>4363.3767</td>
</tr>
<tr>
<td>4</td>
<td>like</td>
<td>283</td>
<td>3606.8067</td>
</tr>
<tr>
<td>5</td>
<td>like very much</td>
<td>236</td>
<td>3005.7000</td>
</tr>
</tbody>
</table>

Probabilities modeled are cumulated over the lower Ordered Values.

The sample and analysis summary is shown in Output 69.1.2. There are five response levels for the Rating with ‘dislike very much’ as the lowest ordered value. The regression model is modeling lower cumulative probabilities using logit as the link function. Because the TOTAL= option is used, the finite population correction is included in the variance estimation. The sampling weight is also used in the analysis.

Output 69.1.3.  Web Design Survey, Testing the Proportional Odds Assumption

Score Test for the Proportional Odds Assumption

<table>
<thead>
<tr>
<th>Chi-Square</th>
<th>DF</th>
<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>98.1957</td>
<td>6</td>
<td>&lt;.0001</td>
</tr>
</tbody>
</table>

In Output 69.1.3, the score chi-square for testing the proportional odds assumption is 98.1957, which is highly significant. This indicates that the cumulative logit model may not adequately fit the data.

An alternative model is to use the generalized logit model with the LINK=GLOGIT option as shown in the following SAS statements:

```
proc surveylogistic data=WebSurvey total=Enrollment;
  stratum Class;
```
The `REF='neutral'` option is used for the response variable `Rating` to indicate that all other response levels are referenced to the level 'neutral.' The option `LINK=GLOGIT` option requests the procedure to fit a generalized logit model.

**Output 69.1.4.** Web Design Survey, Model Information

The summary of the analysis is shown in Output 69.1.4, which indicates that the generalized logit model is used in the analysis.

**Output 69.1.5.** Web Design Survey, Class Level Information
Output 69.1.5 shows the parameterization for the main effect Design.

Output 69.1.6. Web Design Survey, Parameter and Odds Ratio Estimates

The parameter and odds ratio estimates are are shown in Output 69.1.6. For each odds ratio estimate, its 95% confidence limits shown in the table contain the value 1.0. Therefore, no conclusion can be made based on this survey about which Web design is preferred.

Example 69.2. The Household Component of the Medical Expenditure Panel Survey (MEPS)

The Household Component of the Medical Expenditure Panel Survey (MEPS-HC) is designed to produce national and regional estimates of the health care use, expenditures, sources of payment, and insurance coverage of the U.S. civilian noninstitutionalized population (MEPS Fact Sheet, 2001). The sample design of the survey includes stratification, clustering, multiple stages of selection, and disproportionate sampling. Furthermore, the MEPS sampling weights reflect adjustments for survey nonresponse and adjustments to population control totals from the Current Population Survey (Computing Standard Errors for MEPS Estimates, 2003).

In this example, the 1999 full-year consolidated data file HC-038 (PUF Data Files, 2002) from the MEPS is used to investigate the relationship between med-
ical insurance coverage and the demographic variables. The data can be downloaded directly from the Agency for Healthcare Research and Quality (AHRQ) Web site (http://www.meps.ahrq.gov/Puf/PufDetail.asp?ID=93) in either ASCII format or SAS transport format. The Web site includes a detailed description of the data as well as the SAS program code used to access and to format it.

For this example, the SAS transport format data file for HC-038 is downloaded to ‘C:H38.ssp’ on a Windows-based PC. The instructions on the Web site lead to the following SAS statements for creating a SAS data set named MEPS, which contains only the sample design variables and other variables necessary for this analysis.

```
proc format;
  value racex
    -9 = 'NOT ASCERTAINED'
    -8 = 'DK'
    -7 = 'REFUSED'
    -1 = 'INAPPLICABLE'
    1 = 'AMERICAN INDIAN'
    2 = 'ALEUT, ESKIMO'
    3 = 'ASIAN OR PACIFIC ISLANDER'
    4 = 'BLACK'
    5 = 'WHITE'
    91 = 'OTHER'
  ;
  value sex
    -9 = 'NOT ASCERTAINED'
    -8 = 'DK'
    -7 = 'REFUSED'
    -1 = 'INAPPLICABLE'
    1 = 'MALE'
    2 = 'FEMALE'
  ;
  value povcat9h
    1 = 'NEGATIVE OR POOR'
    2 = 'NEAR POOR'
    3 = 'LOW INCOME'
    4 = 'MIDDLE INCOME'
    5 = 'HIGH INCOME'
  ;
  value inscov9f
    1 = 'ANY PRIVATE'
    2 = 'PUBLIC ONLY'
    3 = 'UNINSURED'
  ;
run;

libname puflib 'C:';
filename in1 'C:H38.ssp';
proc xcopy in=in1 out=puflib import;
run;

data meps; set puflib.H38;
  label racex= sex= inscov99= povcat99= varstr99= varpsu99= perwt99f= totexp99=;
```
There are a total of 24,618 observations in this SAS data set. Each observation corresponds to a person in the survey. The stratification variable is VARSTR99, which identifies the 143 strata in the sample. The variable VARPSU99 identifies the 460 PSUs in the sample. The sampling weights are stored in the variable PERWT99F. The response variable is the health insurance coverage indicator variable, INSCOV99, which has three values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>the person had any private insurance coverage any time during 1999</td>
</tr>
<tr>
<td>2</td>
<td>the person had only public insurance coverage during 1999</td>
</tr>
<tr>
<td>3</td>
<td>the person was uninsured during all of 1999</td>
</tr>
</tbody>
</table>

The demographic variables include gender (SEX), race (RACEX), and family income level as a percent of the poverty line (POVCAT99). The variable RACEX has five categories:

<table>
<thead>
<tr>
<th>Value</th>
<th>Race Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>American Indian</td>
</tr>
<tr>
<td>2</td>
<td>Aleut, Eskimo</td>
</tr>
<tr>
<td>3</td>
<td>Asian or Pacific Islander</td>
</tr>
<tr>
<td>4</td>
<td>Black</td>
</tr>
<tr>
<td>5</td>
<td>White</td>
</tr>
</tbody>
</table>

The variable POVCAT99 is constructed by dividing family income by the applicable poverty line (based on family size and composition), with the resulting percentages grouped into five categories:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>negative or poor (less than 100%)</td>
</tr>
<tr>
<td>2</td>
<td>near poor (100% to less than 125%)</td>
</tr>
<tr>
<td>3</td>
<td>low income (125% to less than 200%)</td>
</tr>
<tr>
<td>4</td>
<td>middle income (200% to less than 400%)</td>
</tr>
<tr>
<td>5</td>
<td>high income (greater than or equal to 400%)</td>
</tr>
</tbody>
</table>

The data set also contains the total health care expenditure in 1999, TOTEXP99, which is used as a covariate in the analysis.

</tbody>
</table>

Output 69.2.1 displays the first 30 observations of this data set.

The following SAS statements fit a generalized logit model for the 1999 full-year consolidated MEPS data.

```sas
proc surveylogistic data=meps;
  stratum VARSTR99;
  cluster VARPSU99;
  weight PERWT99F;
  class SEX RACEX POVCAT99;
  model INSCOV99 = TOTEXP99 SEX RACEX POVCAT99 / link=glogit;
run;
```

The STRATUM statement specifies the stratification variable VARSTR99. The CLUSTER statement specifies the PSU variable VARPSU99. The WEIGHT statement specifies the sample weight variable PERWT99F. The demographic variables
SEX, RACEX, and POVCAT99 are listed in the CLASS statement to indicate that they are categorical independent variables in the MODEL statement. In the MODEL statement, the response variable is INSCOV99, and the independent variables are TOTEXP99 along with the selected demographic variables. The LINK= option requests the procedure to fit the generalized logit model because the response variable INSCOV99 has nominal responses.

The results of this analysis are shown in the following tables.

**Output 69.2.2.** MEPS, Model Information

<table>
<thead>
<tr>

Output 69.2.7 displays the odds ratio estimates and their standard errors.

For example, after adjusting for the effects of sex, race, and total health care expenditures, a person with high income is estimated to be 11.595 times more likely than a poor person to choose private health care insurance over no insurance, but only 0.274 times as likely to choose public health insurance over no insurance.

REFERENCES ............................................. 4361
The SURVEYMEANS procedure produces estimates of survey population means and totals from sample survey data. The procedure also produces variance estimates, confidence limits, and other descriptive statistics. When computing these estimates, the procedure takes into account the sample design used to select the survey sample. The sample design can be a complex survey sample design with stratification, clustering, and unequal weighting.

PROC SURVEYMEANS uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters, or primary sampling units (PSUs), in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate.

PROC SURVEYMEANS uses the Output Delivery System (ODS) to place results in output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality.

This section demonstrates how you can use the SURVEYMEANS procedure to produce descriptive statistics from sample survey data. For a complete description of PROC SURVEYMEANS, please refer to the “Syntax” section on page 4322. The “Examples” section on page 4350 provides more complicated examples to illustrate the applications of PROC SURVEYMEANS.

Simple Random Sampling

This example illustrates how you can use PROC SURVEYMEANS to estimate population means and proportions from sample survey data. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on average, and what percentage of students spend at least $10 weekly for ice cream.

To answer these questions, 40 students were selected from the entire student population using simple random sampling (SRS). Selection by simple random sampling means that all students have an equal chance of being selected, and no student can be selected more than once. Each student selected for the sample was asked how much
he spends for ice cream per week, on average. The SAS data set named IceCream saves the responses of the 40 students:

```sas
data IceCream;
  input Grade Spending @@;
  if (Spending < 10) then Group='less';
  else Group='more';
datalines;
7 7 7 7 8 12 9 10 7 1 7 10 7 3 8 20 8 19 7 2
7 2 9 15 8 16 7 6 7 6 7 6 9 15 8 17 8 14 9 8
9 8 9 7 7 3 7 12 7 4 9 14 8 18 9 9 7 2 7 1
7 4 7 11 9 8 8 10 8 13 7 2 9 6 9 11 7 2 7 9
;
```

The variable Grade contains a student’s grade. The variable Spending contains a student’s response on how much he spends per week for ice cream, in dollars. The variable Group is created to indicate whether a student spends at least $10 weekly for ice cream: Group='more' if a student spends at least $10, or Group='less' if a student spends less than $10.

You can use PROC SURVEYMEANS to produce estimates for the entire student population, based on this random sample of 40 students:

```sas
title1 'Analysis of Ice Cream Spending';
title2 'Simple Random Sample Design';
proc surveymeans data=IceCream total=4000;
  var Spending Group;
run;
```

The PROC SURVEYMEANS statement invokes the procedure. The TOTAL=4000 option specifies the total number of students in the study population, or school. The procedure uses this total to adjust variance estimates for the effects of sampling from a finite population. The VAR statement names the variables to analyze, Spending and Group.

**Figure 70.1** displays the results from this analysis. There are a total of 40 observations used in the analysis. The “Class Level Information” table lists the two levels of the variable Group. This variable is a character variable, and so PROC SURVEYMEANS provides a categorical analysis for it, estimating the relative frequency or proportion for each level. If you want a categorical analysis for a numeric variable, you can name that variable in the CLASS statement.

Figure 70.1. Analysis of Ice Cream Spending, Simple Random Sample Design

The “Statistics” table displays the estimates for each analysis variable. By default, PROC SURVEYMEANS displays the number of observations, the estimate of the mean, its standard error, and 95% confidence limits for the mean. You can obtain other statistics by specifying the corresponding statistic-keywords in the PROC SURVEYMEANS statement.

The estimate of the average weekly ice cream expense is $8.75 for students in this school. The standard error of this estimate if $0.85, and the 95% confidence interval for weekly ice cream expense is from $7.04 to $10.46.

The analysis variable Group is a character variable, and so PROC SURVEYMEANS analyzes it as categorical, estimating the relative frequency or proportion for each level or category. These estimates are displayed in the Mean column of the “Statistics” table. It is estimated that 57.5% of all students spend less than $10 weekly on ice cream, while 42.5% of the students spend at least $10 weekly. The standard error of each estimate is 7.9%.
Stratified Sampling

Suppose that the sample of students described in the previous section was actually selected using stratified random sampling. In stratified sampling, the study population is divided into nonoverlapping strata, and samples are selected from each stratum independently.

The list of students in this junior high school was stratified by grade, yielding three strata: grades 7, 8, and 9. A simple random sample of students was selected from each grade. Table 70.1 shows the total number of students in each grade.

Table 70.1. Number of Students by Grade

<table>
<thead>
<tr>
<th>Grade</th>
<th>Number of Students</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1,824</td>
</tr>
<tr>
<td>8</td>
<td>1,025</td>
</tr>
<tr>
<td>9</td>
<td>1,151</td>
</tr>
<tr>
<td>Total</td>
<td>4,000</td>
</tr>
</tbody>
</table>

To analyze this stratified sample, you need to provide the population totals for each stratum to PROC SURVEYMEANS. The SAS data set named StudentTotals contains the information from Table 70.1:

```sas
data StudentTotals;
  input Grade _total_; datalines;
  7 1824
  8 1025
  9 1151;
;
```

The variable Grade is the stratum identification variable, and the variable _TOTAL_ contains the total number of students for each stratum. PROC SURVEYMEANS requires you to use the variable name _TOTAL_ for the stratum population totals.

The procedure uses the stratum population totals to adjust variance estimates for the effects of sampling from a finite population. If you do not provide population totals or sampling rates, then the procedure assumes that the proportion of the population in the sample is very small, and the computation does not involve a finite population correction.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information in order to produce an unbiased mean estimator. In this example, the appropriate sampling weights are reciprocals of the probabilities of selection. You can use the following data step to create the sampling weights:

```sas
data IceCream;
  set IceCream;
  if Grade=7 then Prob=20/1824;
  if Grade=8 then Prob=9/1025;
  if Grade=9 then Prob=11/1151;
  Weight=1/Prob;
```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following SAS statements perform the stratified analysis of the survey data:

```sas
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
   stratum Grade / list;
   var Spending Group;
   weight Weight;
run;
```

The PROC SURVEYMEANS statement invokes the procedure. The DATA= option names the SAS data set `IceCream` as the input data set to be analyzed. The TOTAL= option names the data set `StudentTotals` as the input data set containing the stratum population totals. Comparing this to the analysis in the “Simple Random Sampling” section on page 4315, notice that the TOTAL= `StudentTotals` option is used here instead of the TOTAL=4000 option. In this stratified sample design, the population totals are different for different strata, and so you need to provide them to PROC SURVEYMEANS in a SAS data set.

The STRATA statement identifies the stratification variable `Grade`. The LIST option in the STRATA statement requests that the procedure display stratum information. The WEIGHT statement tells the procedure that the variable `Weight` contains the sampling weights.

![Analysis of Ice Cream Spending](image)

**Figure 70.2.** Data Summary

*Figure 70.2* displays information on the input data set. There are three strata in the design, and 40 observations in the sample. The categorical variable `Group` has two levels, ‘less’ and ‘more’.

Figure 70.3. Stratum Information

Figure 70.3 displays information for each stratum. The table displays a Stratum Index and the values of the STRATA variable. The Stratum Index identifies each stratum by a sequentially assigned number. For each stratum, the table gives the population total (total number of students), the sampling rate, and the sample size. The stratum sampling rate is the ratio of the number of students in the sample to the number of students in the population for that stratum. The table also lists each analysis variable and the number of stratum observations for that variable. For categorical variables, the table lists each level and the number of sample observations in that level.

Figure 70.4. Analysis of Ice Cream Spending, Stratified SRS Design
Figure 70.4 shows that

- the estimate of average weekly ice cream expense is $9.14 for students in this school, with a standard error of $0.53, and a 95% confidence interval from $8.06 to $10.22.
- an estimate of 54.5% of all students spend less than $10 weekly on ice cream, and 45.5% spend more, with a standard error of 5.8%.

Output Data Set

PROC SURVEYMEANS uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

For example, to save the “Statistics” table shown in Figure 70.4 in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```sas
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
  stratum Grade / list;
  var Spending Group;
  weight Weight;
  ods output Statistics=MyStat;
run;
```

The statement

```sas
ods output Statistics=MyStat;
```

requests that the “Statistics” table that appears in Figure 70.4 be placed in a SAS data set named MyStat.

The PRINT procedure displays observations of the data set MyStat:

```sas
proc print data=MyStat;
run;
```

Figure 70.5 displays the data set MyStat.

Figure 70.5. The Data Set MyStat

The section “ODS Table Names” on page 4349 gives the complete list of the tables produced by PROC SURVEYMEANS.

Syntax

The following statements are available in PROC SURVEYMEANS.

```
PROC SURVEYMEANS < options > < statistic-keywords > ;
   BY variables ;
   CLASS variables ;
   CLUSTER variables ;
   DOMAIN variables < variable=variable
                     variable=variable=variable ... > ;
   RATIO < 'label' > variables / variables ;
   STRATA variables < / option > ;
   VAR variables ;
   WEIGHT variable ;
```

The PROC SURVEYMEANS statement invokes the procedure. It optionally names the input data sets and specifies statistics for the procedure to compute. The PROC SURVEYMEANS statement is required.

The VAR statement identifies the variables to be analyzed. The CLASS statement identifies those numeric variables that are to be analyzed as categorical variables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The DOMAIN statement lists the variables that define domains for subpopulation analysis. The RATIO statement requests ratio analysis for means or proportions of analysis variables. The WEIGHT statement names the sampling
weight variable. You can use a BY statement with PROC SURVEYMEANS to obtain separate analyses for groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYMEANS statement and the WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLASS, CLUSTER, DOMAIN, RATIO, STRATA, VAR, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYMEANS statement.

**PROC SURVEYMEANS Statement**

```
PROC SURVEYMEANS < options > < statistic-keywords > ;
```

The PROC SURVEYMEANS statement invokes the procedure. In this statement, you identify the data set to be analyzed and specify sample design information. The DATA= option names the input data set to be analyzed. If your analysis includes a finite population correction factor, you can input either the sampling rate or the population total using the RATE= or TOTAL= option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set containing the stratification variables.

In the PROC SURVEYMEANS statement, you also can use statistic-keywords to specify statistics for the procedure to compute. Available statistics include the population mean and population total, together with their variance estimates and confidence limits. You can also request data set summary information and sample design information.

You can specify the following options in the PROC SURVEYMEANS statement:

**ALPHA=α**

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of $\alpha$ produces $100(1 - \alpha)$% confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

**DATA=SAS-data-set**

specifies the SAS data set to be analyzed by PROC SURVEYMEANS. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**MISSING**

requests that the procedure treat missing values as a valid category for all categorical variables, which include categorical analysis variables, strata variables, cluster variables, and domain variables.

**ORDER=DATA | FORMATTED | INTERNAL**

specifies the order in which the values of the categorical variables are to be reported. The following shows how PROC SURVEYMEANS interprets values of the ORDER= option:

```
DATA orders values according to their order in the input data set.
```
FORMATTED orders values by their formatted values. This order is operating environment dependent. By default, the order is ascending.

INTERNAL orders values by their unformatted values, which yields the same order that the SORT procedure does. This order is operating environment dependent.

By default, ORDER=FORMATTED.

The ORDER= option applies to all the categorical variables. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

RATE=value | SAS-data-set
R=value | SAS-data-set

specifies the sampling rate as a nonnegative value, or names an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for variance estimation. If your sample design has multiple stages, you should specify the first-stage sampling rate, which is the ratio of the number of PSUs selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative value for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section “Specification of Population Totals and Sampling Rates” on page 4334 for more details.

The sampling rate value must be a nonnegative number. You can specify value as a number between 0 and 1. Or you can specify value in percentage form as a number between 1 and 100, and PROC SURVEYMEANS will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

STACKING
requests the procedure to produce the output data sets using a stacking table structure, which was the default in releases prior to Version 9. The new default is to produce a rectangular table structure in the output data sets.

The STACKING option affects the following tables:

- Domain
- Ratio
- Statistics
- StrataInfo
When you use the ODS statement to create SAS data sets for these tables in the output, the data set structure can be either stacking or rectangular. A rectangular structure creates one observation for each analysis variable in the data set. However, if you use the STACKING option in Version 9, the procedure creates only one observation in the output data set for all analysis variables. The following example shows these two structures in output data sets.

```sas
data new;
  input sex$ x;
  datalines;
  M 12
  F 5
  M 13
  F 23
  F 11
;

  proc surveymeans data=new mean;
    ods output statistics=rectangle;
  run;

  proc print data=rectangle;
  run;

  proc surveymeans data=new mean stacking;
    ods output statistics=stacking;
  run;

  proc print data=stacking;
  run;
```

Figure 70.6 shows the rectangular structure of the output data set for the statistics table.

**Figure 70.7.** Stacking Structure in the Output Data Set

**TOTAL=** value | SAS-data-set

N=value | SAS-data-set

specifies the total number of primary sampling units (PSUs) in the study population as a positive value, or names an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive value for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section “Specification of Population Totals and Sampling Rates” on page 4334 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

**statistic-keywords**

specifies the statistics for the procedure to compute. If you do not specify any statistic-keywords, PROC SURVEYMEANS computes the NOBS, MEAN, STDERR, and CLM statistics by default.

The statistics produced depend on the type of the analysis variable. If you name a numeric variable in the CLASS statement, then the procedure analyzes that variable as a categorical variable. The procedure always analyzes character variables as categorical. See the section “CLASS Statement” on page 4329 for more information.

PROC SURVEYMEANS computes MIN, MAX, and RANGE for numeric variables but not for categorical variables. For numeric variables, the keyword MEAN produces the mean, but for categorical variables it produces the proportion in each category or level. Also for categorical variables, the keyword NOBS produces the number of observations for each variable level, and the keyword NMISS produces the number of missing observations for each level. If you request the keyword NCLUSTER for a categorical variable, PROC SURVEYMEANS displays for each level the number of clusters with observations in that level. PROC SURVEYMEANS computes SUMWGT in the same way for both categorical and numeric variables, as the sum of the weights over all nonmissing observations.
PROC SURVEYMEANS performs univariate analysis, analyzing each variable separately. Thus the number of nonmissing and missing observations may not be the same for all analysis variables. See the section “Missing Values” on page 4333 for more information.

If you use the keyword RATIO without the keyword MEAN, the keyword MEAN is implied.

Other available statistics computed for a ratio are N, NCLU, SUMWGT, RATIO, STDERR, DF, T, PROBT, and CLM, as listed below. If no statistics are requested, the procedure will compute the ratio and its standard error by default for a RATIO statement.

The valid statistic-keywords are as follows:

- **ALL**: all statistics listed
- **CLM**: 100(1 − α)% two-sided confidence limits for the MEAN, where α is determined by the `ALPHA=` option described on page 4323, and the default is α = 0.05
- **CLSUM**: 100(1 − α)% two-sided confidence limits for the SUM, where α is determined by the `ALPHA=` option described on page 4323, and the default is α = 0.05
- **CV**: coefficient of variation for MEAN
- **CVSUM**: coefficient of variation for SUM
- **DF**: degrees of freedom for the t test
- **LCLM**: 100(1 − α)% one-sided lower confidence limit of the MEAN, where α is determined by the `ALPHA=` option described on page 4323, and the default is α = 0.05
- **LCLMSUM**: 100(1 − α)% one-sided lower confidence limit of the SUM, where α is determined by the `ALPHA=` option described on page 4323, and the default is α = 0.05
- **MAX**: maximum value
- **MEAN**: mean for a numeric variable, or the proportion in each category for a categorical variable
- **MIN**: minimum value
- **NCLUSTER**: number of clusters
- **NMISS**: number of missing observations
- **NOBS**: number of nonmissing observations
- **RANGE**: range, MAX−MIN
- **RATIO**: ratio of means or proportions
- **STD**: standard deviation of the SUM. When you request SUM, the procedure computes STD by default.
- **STDERR**: standard error of the MEAN or RATIO. When you request MEAN or RATIO, the procedure computes STDERR by default.
SUM weighted sum, $\sum w_i y_i$, or estimated population total when the appropriate sampling weights are used.

SUMWGT sum of the weights, $\sum w_i$.

T $t$-value and its corresponding $p$-value with DF degrees of freedom for $H_0: \theta = 0$

where $\theta$ is the population mean or the population ratio.

UCLM $100(1 - \alpha)\%$ one-sided upper confidence limit of the MEAN, where $\alpha$ is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$.

UCLMSUM $100(1 - \alpha)\%$ one-sided upper confidence limit of the SUM, where $\alpha$ is determined by the ALPHA= option described on page 4323, and the default is $\alpha = 0.05$.

VAR variance of the MEAN or RATIO.

VARSUM variance of the SUM.

See the section “Statistical Computations” on page 4336 for details on how PROC SURVEYMEANS computes these statistics.

**BY Statement**

```
BY  variables ;
```

You can specify a BY statement with PROC SURVEYMEANS to obtain separate analyses on observations in groups defined by the BY variables. 

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. You should use the DOMAIN statement to obtain domain analysis.

When a BY statement appears, the procedure expects the input data sets to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Use the BY statement options NOTSORTED or DESCENDING in the BY statement. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
• Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

**CLASS Statement**

```
CLASS | CLASSES variables ;
```

The CLASS statement names variables to be analyzed as categorical variables. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. PROC SURVEYMEANS always analyzes character variables as categorical. If you want categorical analysis for a numeric variable, you must include that variable in the CLASS statement.

The CLASS variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLASS variables determine the categorical variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

You can use multiple CLASS statements to specify categorical variables.

When you specify class variables, you may use the SAS system option SUMSIZE= to limit (or to specify) the amount of memory that is available for data analysis. Refer to the chapter on SAS System options in SAS Language Reference: Dictionary for a description of the SUMSIZE= option.

**CLUSTER Statement**

```
CLUSTER | CLUSTERS variables ;
```

The CLUSTER statement names variables that identify the clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement. See the section “Primary Sampling Units (PSUs)” on page 4335 for more information.

The CLUSTER variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.
You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

**DOMAIN Statement**

```
DOMAIN SUBGROUP variables < variable * variable variable * variable ... >;
```

The DOMAIN statement requests analysis for subpopulations, or domains, in addition to analysis for the entire study population. The DOMAIN statement names the variables that identify domains, which are called domain variables.

It is common practice to compute statistics for domains. The formation of these domains may be unrelated to the sample design. Therefore, the sample sizes for the domains are random variables. In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement.

Note that a DOMAIN statement is different from a BY statement. In a BY statement, you treat the sample sizes as fixed in each subpopulation, and you perform analysis within each BY group independently. See the section “Domain Statistics” on page 4342 for more details.

A domain variable can be either character or numeric. However, the procedure treats domain variables as categorical variables. If a variable appears by itself in a DOMAIN statement, each level of this variable determines a domain in the study population. If two or more variables are joined by asterisks (*), then every possible combination of levels of the variables determines a domain. The procedure performs a descriptive analysis within each domain defined by the domain variables.

The formatted values of the domain variables determine the categorical variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

**RATIO Statement**

```
RATIO < 'label' > variables / variables;
```

The RATIO statement requests ratio analysis for means or proportions of analysis variables. A ratio statement names the variables whose means will be used as numerators or denominators in a ratio. Variables appearing before the slash (/), called **numerator variables**, are used for numerators. Variables appearing after the slash (/), called **denominator variables**, are used for denominators. These variables can be any number of analysis variables, either continuous or categorical, in the input data set.

You can optionally specify a label for each RATIO statement to identify the ratios in the output. Labels must be enclosed in single quotes.

If a RATIO statement does not have any numerator variable or denominator variable specified, the RATIO statement will be ignored.

A numerator or denominator variable must be an analysis variable. That is, if there is a VAR statement, then a numerator or denominator variable must appear in the VAR
If there is no VAR statement, a numerator or denominator variable must be on the default analysis variable list (see the section “VAR Statement” on page 4332). If a numerator or denominator variable is not an analysis variable, it is ignored.

The computation of ratios depends on whether the numerator and denominator variables are continuous or categorical.

For continuous variables, ratios are calculated with the mean of the variables. For example, for continuous variables $X$, $Y$, $Z$, and $T$, the following RATIO statement requests the procedure to analyze the ratios $\bar{x}/\bar{z}$, $\bar{x}/\bar{t}$, $\bar{y}/\bar{z}$, and $\bar{y}/\bar{t}$:

```
ratio x y / z t;
```

If a continuous variable appears as both a numerator and a denominator variable, the ratio of this variable itself is ignored.

For categorical variables, ratios are calculated with the proportions for the categories of a categorical variable. For example, if categorical variable Gender has values “Male” and “Female,” with proportions $p_m = \Pr(\text{Gender} = \text{"Male"})$ and $p_f = \Pr(\text{Gender} = \text{"Female"})$, and $Y$ is a continuous variable, then the following RATIO statement requests the procedure to analyze the ratios $p_m/p_f$, $p_f/p_m$, $\bar{y}/p_m$, and $\bar{y}/p_f$:

```
ratio Gender y / Gender;
```

If a categorical variable appears as both a numerator and a denominator variable, then the ratios of the proportions for all categories are computed, except the ratio of each category with itself.

You may have more than one RATIO statement. Each RATIO statement produces ratios independently using its own numerator and denominator variables. Each RATIO statement also produces its own ratio analysis table.

Available statistics for a ratio are:

- $N$, number of observations used to compute the ratio
- $NCLU$, number of clusters
- $SUMWGT$, sum of weights
- $RATIO$, ratio
- $STDERR$, standard error of ratio
- $VAR$, variance of ratio
- $T$, $t$-value of ratio
- $PROBT$, $p$-value of $t$
- $DF$, degrees of freedom of $t$
- $CLM$, two-sided confidence limits of ratio
- $UCLM$, one-sided upper confidence limit of ratio
Chapter 70. The SURVEYMEANS Procedure

- LCLM, one-sided lower confidence limit of ratio

The procedure will calculate these statistics based on the statistic-keywords described on page 4326 which you specified in the PROC statement. If a statistic-keyword is not appropriate for RATIO statement, that statistic-keyword is ignored. If no valid statistics are requested for a RATIO statement, the procedure will compute the ratio and its standard error by default.

Note that ratios within a domain are currently not available.

When calculating the means or proportions for the numerator and denominator variables in a ratio, an observation is excluded if it has a missing value in either the continuous numerator variable or the denominator variable. An observation with missing values is also excluded for the categorical numerator or denominator variables, unless the MISSING option is used.

### STRATA Statement

```
STRATA | STRATUM  variables < / option > ;
```

The STRATA statement names variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specification of Population Totals and Sampling Rates” on page 4334 for more information.

The STRATA variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the SAS Procedures Guide.

You can specify the following option in the STRATA statement after a slash (/):

- **LIST**

  displays a “Stratum Information” table, which includes values of the STRATA variables and sampling rates for each stratum. This table also provides the number of observations and number of clusters for each stratum and analysis variable. See the section “Displayed Output” on page 4345 for more details.

### VAR Statement

```
VAR  variables ;
```

The VAR statement names the variables to be analyzed.

If you want a categorical analysis for a numeric variable, you must also name that variable in the CLASS statement. For categorical variables, PROC SURVEYMEANS estimates the proportion in each category or level, instead of the overall mean. Character variables are always analyzed as categorical variables. See the section “CLASS Statement” on page 4329 for more information.
If you do not specify a VAR statement, then PROC SURVEYMEANS analyzes all variables in the DATA= input data set, except those named in the BY, CLUSTER, STRATA, and WEIGHT statements.

**WEIGHT Statement**

```plaintext
WEIGHT | WGT  variable ;
```

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYMEANS assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

**Details**

**Missing Values**

When computing statistics for an analysis variable, PROC SURVEYMEANS omits observations with missing values for that variable. The procedure bases statistics for each variable only on observations that have nonmissing values for that variable. If you specify the `MISSING` option described on page 4323 in the PROC SURVEYMEANS statement, the procedure treats missing values of a categorical variable as a valid category.

An observation is also excluded if it has a missing value for any STRATA or CLUSTER variable, unless the `MISSING` option is used.

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYMEANS excludes that observation from the analysis.

The procedure performs univariate analysis and analyzes each VAR variable separately. Thus, the number of missing observations may be different for different variables. You can specify the keyword NMISS in the PROC SURVEYMEANS statement to display the number of missing values for each analysis variable in the “Statistics” table.

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. An observation without missing values is called a complete respondent, and an observation with missing values is called an incomplete respondent. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then the survey estimates will be biased and will not accurately represent the survey population. A variety of techniques in sample design and survey operations can reduce nonresponse. Once data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYMEANS. Refer to Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more details.
PROC SURVEYMEANS assumes that missing data are missing at random, because the patterns of missing data are unknown. Therefore, PROC SURVEYMEANS excludes those observations with missing values.

If there is evidence indicating that the missing data are not at random, for example, if complete respondents are different from incomplete respondents for your study, you can use the DOMAIN statement to compute the descriptive statistics among complete respondents from your survey data without imputation on incomplete respondents. See Example 70.4 on page 4358.

If missing values result in empty strata in the sample, then they will have an impact on the statistical computation, which uses the total number of strata. If all the observations in a stratum have missing weights or missing values for the current analysis variable, this stratum is an empty stratum. For example,

```plaintext
data new;
  input stratum y z w;
datalines;
1 . 13 40
1 2 9 .
1 . 5 25
2 5 10 20
2 8 60 15 ;
proc surveymeans df mean nobs nmiss;
  strata stratum;
  var y z;
  weight w;
run;
```

You analyze variable \( Y \) and \( Z \), with weight variable \( W \) and stratum variable \( \text{STRATUM} \). For variable \( Y \), all observations have missing values or missing weights in \( \text{STRATUM}=1 \), therefore, the analysis for variable \( Y \) uses only observations in \( \text{STRATUM}=2 \). Thus, for variable \( Y \), \( \text{STRATUM}=1 \) is an empty stratum and \( \text{STRATUM}=2 \) is a non-empty stratum. Note, however, that \( \text{STRATUM}=1 \) is a non-empty stratum for variable \( Z \).

If your sample design contains stratification, PROC SURVEYMEANS analyzes only the data in non-empty strata. Therefore, the total number of strata for an analysis variable means the total number of non-empty strata. In this example, the total number of strata for \( Y \) and \( Z \) is one and two, respectively.

## Survey Data Analysis

### Specification of Population Totals and Sampling Rates

If your analysis should include a finite population correction (fpc), you can input either the sampling rate or the population total using the RATE= option or the TOTAL= option. (You cannot specify both of these options in the same PROC SURVEYMEANS statement.) If you do not specify one of these options, the procedure does not use the fpc when computing variance estimates. For fairly small
sampling fractions, it is appropriate to ignore this correction. Refer to Cochran (1977) and Kish (1965).

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population. See the section “Primary Sampling Units (PSUs)” on page 4335 for more details. For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you should use the RATE=value option or the TOTAL=value option. If your sample design is stratified with different sampling rates or population totals in the strata, then you can use the RATE=SAS-data-set option or the TOTAL=SAS-data-set option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a secondary data set, as opposed to the primary data set that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=SAS-data-set option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. Or if you specify the RATE=SAS-data-set option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The value in the RATE= option or the values of _RATE_ in the secondary data set must be nonnegative numbers. You can specify value as a number between 0 and 1. Or you can specify value in percentage form as a number between 1 and 100, and PROC SURVEYMEANS will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=value option, value must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

**Primary Sampling Units (PSUs)**

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs. See the section “Variance and Standard Error of the Mean” on page 4338 and the section “Variance and Standard Deviation of the Total” on page 4341. You can use the CLUSTER statement to identify the first stage clusters in your design. PROC SURVEYMEANS assumes that each cluster represents a PSU in the sample and that each observation is an element of a PSU. If you do not specify a CLUSTER statement, the procedure treats each observation as a PSU.
Domain Analysis

It is common practice to compute statistics for subpopulations, or domains, in addition to computing statistics for the entire study population. Analysis for domains using the entire sample is called domain analysis (subgroup analysis, subpopulation analysis, subdomain analysis). The formation of these subpopulations of interest may be unrelated to the sample design. Therefore, the sample sizes for the subpopulations may actually be random variables.

In order to incorporate this variability into the variance estimation, you should use a DOMAIN statement. Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. For more detailed information about domain analysis, refer to Kish (1965).

Statistical Computations

The SURVEYMEANS procedure uses the Taylor expansion method to estimate sampling errors of estimators based on complex sample designs. This method obtains a linear approximation for the estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971, Fuller 1975). When there are clusters, or PSUs, in the sample design, the procedure estimates variance from the variation among PSUs. When the design is stratified, the procedure pools stratum variance estimates to compute the overall variance estimate. For \( t \) tests of the estimates, the degrees of freedom equals the number of clusters minus the number of strata in the sample design.

For a multistage sample design, the variance estimation method depends only on the first stage of the sample design. So, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

Quite often in complex surveys, respondents have unequal weights, which reflect unequal selection probabilities and adjustments for nonresponse. In such surveys, the appropriate sampling weights must be used to obtain valid estimates for the study population.

For more information on the analysis of sample survey data, refer to Lee, Forthoffer, and Lorimor (1989), Cochran (1977), Kish (1965), and Hansen, Hurwitz, and Madow (1953).

Definition and Notation

For a stratified clustered sample design, together with the sampling weights, the sample can be represented by an \( n \times (P + 1) \) matrix

\[
(w, Y) = \begin{pmatrix}
wh_{ij}, y_{hij} \\
wh_{ij}, y_{hij}^{(1)}, y_{hij}^{(2)}, \ldots, y_{hij}^{(P)}
\end{pmatrix}
\]
where

- $h = 1, 2, \ldots, H$ is the stratum number, with a total of $H$ strata
- $i = 1, 2, \ldots, n_h$ is the cluster number within stratum $h$, with a total of $n_h$ clusters
- $j = 1, 2, \ldots, m_{hi}$ is the unit number within cluster $i$ of stratum $h$, with a total of $m_{hi}$ units
- $p = 1, 2, \ldots, P$ is the analysis variable number, with a total of $P$ variables
- $n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi}$ is the total number of observations in the sample
- $w_{hij}$ denotes the sampling weight for observation $j$ in cluster $i$ of stratum $h$
- $y_{hij} = \left( y_{hij}^{(1)}, y_{hij}^{(2)}, \ldots, y_{hij}^{(P)} \right)$ are the observed values of the analysis variables for observation $j$ in cluster $i$ of stratum $h$, including both the values of numerical variables and the values of indicator variables for levels of categorical variables.

For a categorical variable $C$, let $l$ denote the number of levels of $C$, and denote the level values as $c_1, c_2, \ldots, c_l$. Then there are $l$ indicator variables associated with these levels. That is, for level $C = c_k (k = 1, 2, \ldots, l)$, a $y^{(q)} (q \in \{1, 2, \ldots, P\})$ contains the values of the indicator variable for the category $C = c_k$, with the value of observation $j$ in cluster $i$ of stratum $h$:

$$y_{hij}^{(q)} = I\{C = c_k\}(h, i, j) = \begin{cases} 1 & \text{if } C_{hij} = c_k \\ 0 & \text{otherwise} \end{cases}$$

Therefore, the total number of analysis variables, $P$, is the total number of numerical variables plus the total number of levels of all categorical variables.

Also, $f_h$ denotes the sampling rate for stratum $h$. You can use the TOTAL= option or the RATE= option to input population totals or sampling rates. See the section “Specification of Population Totals and Sampling Rates” on page 4334 for details. If you input stratum totals, PROC SURVEYMEANS computes $f_h$ as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYMEANS uses these values directly for $f_h$. If you do not specify the TOTAL= option or the RATE= option, then the procedure assumes that the stratum sampling rates $f_h$ are negligible, and a finite population correction is not used when computing variances.

This notation is also applicable to other sample designs. For example, for a sample design without stratification, you can let $H = 1$; for a sample design without clusters, you can let $m_{hi} = 1$ for every $h$ and $i$.

Mean ♦ 4337

When you specify the keyword MEAN, the procedure computes the estimate of the mean (mean per element) from the survey data. Also, the procedure computes the mean by default if you do not specify any statistic-keywords in the PROC SURVEYMEANS statement.
PROC SURVEYMEANS computes the estimate of the mean as
\[
\hat{\bar{Y}} = \left( \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right) / w...
\]

where
\[
w... = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}
\]
is the sum of the weights over all observations in the sample.

**Variance and Standard Error of the Mean**

When you specify the keyword STDERR, the procedure computes the standard error of the mean. Also, the procedure computes the standard error by default if you specify the keyword MEAN, or if you do not specify any statistic-keywords in the PROC SURVEYMEANS statement. The keyword VAR requests the variance of the mean.

PROC SURVEYMEANS uses the Taylor series expansion theory to estimate the variance of the mean \(\hat{\bar{Y}}\). The procedure computes the estimated variance as
\[
\hat{V}(\hat{\bar{Y}}) = \sum_{h=1}^{H} \hat{V}_h(\hat{\bar{Y}})
\]
where if \(n_h > 1\),
\[
\hat{V}_h(\hat{\bar{Y}}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{hi} - \bar{e}_{h..})^2
\]
\[
e_{hi} = \left( \sum_{j=1}^{m_{hi}} w_{hij} (y_{hij} - \hat{\bar{Y}}) \right) / w...
\]
\[
\bar{e}_{h..} = \frac{\sum_{i=1}^{n_h} e_{hi}}{n_h}
\]
and if \(n_h = 1\),
\[
\hat{V}_h(\hat{\bar{Y}}) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H
\end{cases}
\]

The standard error of the mean is the square root of the estimated variance.
\[
\text{StdErr}(\hat{\bar{Y}}) = \sqrt{\hat{V}(\hat{\bar{Y}})}
\]
**Ratio**

When you use a RATIO statement, the procedure produces statistics requested by the statistics-keywords in the PROC SURVEYMEANS statement.

Suppose that you want to calculate the ratio of variable $Y$ over variable $X$. Let $x_{hij}$ be the value of variable $X$ for the $j$th member in cluster $i$ in the $h$th stratum.

The ratio of $Y$ over $X$ is

$$
\hat{R} = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}}{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} x_{hij}}
$$

PROC SURVEYMEANS uses the Taylor series expansion method to estimate the variance of the ratio $\hat{R}$ as

$$
\hat{V}(\hat{R}) = \sum_{h=1}^{H} \hat{V}_h(\hat{R})
$$

where if $n_h > 1$,

$$
\hat{V}_h(\hat{R}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (g_{hi} - \bar{g}_{hi})^2
$$

$$
g_{hi} = \frac{\sum_{j=1}^{m_{hi}} w_{hij} (y_{hij} - x_{hij} \hat{R})}{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} x_{hij}}
$$

$$
\bar{g}_{hi} = \left( \sum_{i=1}^{n_h} g_{hi} \right) / n_h
$$

and if $n_h = 1$,

$$
\hat{V}_h(\hat{R}) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H
\end{cases}
$$

The standard error of the ratio is the square root of the estimated variance.

$$
\text{StdErr}(\hat{R}) = \sqrt{\hat{V}(\hat{R})}
$$

**t Test for the Mean**

If you specify the keyword T, PROC SURVEYMEANS computes the $t$-value for testing that the population mean equals zero, $H_0 : \bar{Y} = 0$. The test statistic equals

$$
t(\hat{\bar{Y}}) = \frac{\hat{\bar{Y}}}{\text{StdErr}(\hat{\bar{Y}})}
$$

The two-sided $p$-value for this test is

$$
\text{Prob}( |T| > |t(\hat{\bar{Y}})| )
$$
where \( T \) is a random variable with the \( t \) distribution with \( df \) degrees of freedom.

PROC SURVEYMEANS calculates the degrees of freedom for the \( t \) test as the number of clusters minus the number of strata. If there are no clusters, then \( df \) equals the number of observations minus the number of strata. If the design is not stratified, then \( df \) equals the number of clusters minus one. The procedure displays \( df \) for the \( t \) test if you specify the keyword DF in the PROC SURVEYMEANS statement.

If missing values or missing weights are present in your data, the number of strata, the number of observations, and the number of clusters are counted based on the observations in non-empty strata. See the section “Missing Values” on page 4333 for details. For degrees of freedom in domain analysis, see the section “Domain Statistics” on page 4342.

**Confidence Limits for the Mean**

If you specify the keyword CLM, the procedure computes two-sided confidence limits for the mean. Also, the procedure includes the confidence limits by default if you do not specify any statistic-keywords in the PROC SURVEYMEANS statement.

The confidence coefficient is determined by the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

\[
\hat{Y} \pm \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha/2}
\]

where \( \hat{Y} \) is the estimate of the mean, \( \text{StdErr}(\hat{Y}) \) is the standard error of the mean, and \( t_{df, \alpha/2} \) is the \( 100(1 - \alpha/2) \) percentile of the \( t \) distribution with \( df \) calculated as described in the section “\( t \) Test for the Mean” on page 4339.

If you specify the keyword UCLM, the procedure computes the one-sided upper \( 100(1 - \alpha) \) confidence limit for the mean:

\[
\hat{Y} + \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha}
\]

If you specify the keyword LCLM, the procedure computes the one-sided lower \( 100(1 - \alpha) \) confidence limit for the mean:

\[
\hat{Y} - \text{StdErr}(\hat{Y}) \cdot t_{df, \alpha}
\]

**Coefficient of Variation**

If you specify the keyword CV, PROC SURVEYMEANS computes the coefficient of variation, which is the ratio of the standard error of the mean to the estimated mean.

\[
cv(\hat{Y}) = \frac{\text{StdErr}(\hat{Y})}{\hat{Y}}
\]

If you specify the keyword CVSUM, PROC SURVEYMEANS computes the coefficient of variation for the estimated total, which is the ratio of the standard deviation of the sum to the estimated total.

\[
cv(Y) = \frac{\text{Std}(\hat{Y})}{\hat{Y}}
\]
**Proportions**

If you specify the keyword MEAN for a categorical variable, PROC SURVEYMEANS estimates the proportion, or relative frequency, for each level of the categorical variable. If you do not specify any statistic-keywords in the PROC SURVEYMEANS statement, the procedure estimates the proportions for levels of the categorical variables, together with their standard errors and confidence limits.

The procedure estimates the proportion in level $c_k$ for variable $C$ as

$$\hat{p} = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}^{(q)}}{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij}}$$

where $y_{hij}^{(q)}$ is the value of the indicator function for level $C = c_k$, defined in the section “Definition and Notation” on page 4336, and $y_{hij}^{(q)}$ equals 1 if the observed value of variable $C$ equals $c_k$, and $y_{hij}^{(q)}$ equals 0 otherwise. Since the proportion estimator is actually an estimator of the mean for an indicator variable, the procedure computes its variance and standard error according to the method outlined in the section “Variance and Standard Error of the Mean” on page 4338. Similarly, the procedure computes confidence limits for proportions as described in the section “Confidence Limits for the Mean” on page 4340.

**Total**

If you specify the keyword SUM, the procedure computes the estimate of the population total from the survey data. The estimate of the total is the weighted sum over the sample.

$$\hat{Y} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij}$$

For a categorical variable level, $\hat{Y}$ estimates its total frequency in the population.

**Variance and Standard Deviation of the Total**

When you specify the keyword STD or the keyword SUM, the procedure estimates the standard deviation of the total. The keyword VARSUM requests the variance of the total.

PROC SURVEYMEANS estimates the variance of the total as

$$\hat{V}(\hat{Y}) = \sum_{h=1}^{H} \hat{V}_h(\hat{Y})$$

where if $n_h > 1$,

$$\hat{V}_h(\hat{Y}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (y_{hi.} - \bar{y}_{h.})^2$$
Chapter 70. The SURVEYMEANS Procedure

\[ y_{hi} = \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \]
\[ \bar{y}_{h..} = \left( \sum_{i=1}^{n_h} y_{hi.} \right) / n_h \]

and if \( n_h = 1 \),

\[ \hat{V}_h(\hat{Y}) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H 
\end{cases} \]

The standard deviation of the total equals

\[ \text{Std}(\hat{Y}) = \sqrt{\hat{V}(\hat{Y})} \]

**Confidence Limits of a Total**

If you specify the keyword CLSUM, the procedure computes confidence limits for the total. The confidence coefficient is determined by the value of the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. The confidence limits are computed as

\[ \hat{Y} \pm \text{Std}(\hat{Y}) \cdot t_{df, \alpha/2} \]

where \( \hat{Y} \) is the estimate of the total, \( \text{Std}(\hat{Y}) \) is the estimated standard deviation, and \( t_{df, \alpha/2} \) is the \( 100(1 - \alpha/2) \) percentile of the \( t \) distribution with \( df \) calculated as described in the section “\( t \) Test for the Mean” on page 4339.

If you specify the keyword UCLSUM, the procedure computes the one-sided upper 100(1 - \( \alpha \)) confidence limit for the sum:

\[ \hat{Y} + \text{Std}(\hat{Y}) \cdot t_{df, \alpha} \]

If you specify the keyword LCLSUM, the procedure computes the one-sided lower 100(1 - \( \alpha \)) confidence limit for the sum:

\[ \hat{Y} - \text{Std}(\hat{Y}) \cdot t_{df, \alpha} \]

**Domain Statistics**

When you use a DOMAIN statement to request a domain analysis, the procedure computes the requested statistics for each domain.

For a domain \( D \), let \( I_D \) be the corresponding indicator variable:

\[ I_D(h, i, j) = \begin{cases} 
1 & \text{if observation } (h, i, j) \text{ belongs to } D \\
0 & \text{otherwise} 
\end{cases} \]
Let
\[ z_{hij} = y_{hij} I_D(h, i, j) = \begin{cases} y_{hij} & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases} \]

The requested statistics for variable \( y \) in domain \( D \) are computed based on the values of \( z \).

**Domain Mean** The estimated mean of \( y \) in the domain \( D \) is
\[
\hat{Y}_D = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{h_i}} v_{hij} z_{hij}}{v_{\ldots}}
\]

where
\[
v_{hij} = w_{hij} I_D(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}
\]
\[
v_{\ldots} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{h_i}} v_{hij}
\]

The variance of \( \hat{Y}_D \) is estimated by
\[
\hat{V}(\hat{Y}_D) = \sum_{h=1}^{H} \hat{V}_h(\hat{Y}_D)
\]

where if \( n_h > 1 \),
\[
\hat{V}_h(\hat{Y}_D) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (r_{hi} - \bar{r}_{h\ldots})^2
\]
\[
r_{hi} = \left( \sum_{j=1}^{m_{h_i}} v_{hij} (z_{hij} - \hat{Y}_D) \right) / v_{\ldots}
\]
\[
\bar{r}_{h\ldots} = \left( \sum_{i=1}^{n_h} r_{hi} \right) / n_h
\]

and if \( n_h = 1 \),
\[
\hat{V}_h(\hat{Y}_D) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H \end{cases}
\]

**Domain Total** The estimated total in domain \( D \) is
\[
\hat{Y}_D = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{h_i}} v_{hij} z_{hij}
\]

\[
\hat{Y}_D = \frac{\sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{h_i}} v_{hij} z_{hij}}{v_{\ldots}}
\]

where
\[
v_{hij} = w_{hij} I_D(h, i, j) = \begin{cases} w_{hij} & \text{if observation } (h, i, j) \text{ belongs to } D \\ 0 & \text{otherwise} \end{cases}
\]
\[
v_{\ldots} = \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{h_i}} v_{hij}
\]
and its estimated variance is

\[ \hat{V}(\hat{Y}_D) = \sum_{h=1}^{H} \hat{V}_h(\hat{Y}_D) \]

where if \( n_h > 1 \),

\[ \hat{V}_h(\hat{Y}_D) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (z_{hi} - \bar{z}_h)^2 \]

\[ z_{hi} = \sum_{j=1}^{m_{hi}} v_{hij} z_{hij} \]

\[ \bar{z}_h = \left( \frac{1}{n_h} \sum_{i=1}^{n_h} z_{hi} \right) / n_h \]

and if \( n_h = 1 \),

\[ \hat{V}_h(\hat{Y}_D) = \begin{cases} 
\text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \ldots, H \\
0 & \text{if } n_{h'} > 1 \text{ for some } 1 < h' < H 
\end{cases} \]

**Degrees of Freedom** For domain analysis, PROC SURVEYMEANS computes the degrees of freedom for \( t \) tests as the number of clusters in the non-empty strata minus the number of non-empty strata. When the sample design has no clusters, the degrees of freedom equals the number of observations in non-empty strata minus the number of non-empty strata. As discussed in the section “Missing Values” on page 4333, missing values and missing weights can result in empty strata. In domain analysis, an empty stratum can also occur when the stratum contains no observations in the specified domain. If no observations in a whole stratum belong to a domain, then this stratum is called an empty stratum for that domain.

For example,

```plaintext
data new;
    input str clu y w d;
    datalines;
    1 1 . 40 9
    1 2 2 . 9
    1 3 . 25 9
    2 4 5 20 9
    2 5 8 15 9
    3 6 5 30 7
    3 7 9 89 7
    3 8 6 23 7
    ;
proc surveymeans df nobs nclu nmiss;
    strata str;
    cluster clu;
    var y;
    weight w;
    domain d;
run;
```
Table 70.2. Calculations of df for Y

<table>
<thead>
<tr>
<th>Non Empty Strata Clusters Used in the Analysis</th>
<th>Domain D=7</th>
<th>Domain D=9</th>
</tr>
</thead>
<tbody>
<tr>
<td>STR=3</td>
<td>CLU=6, CLU=7, and CLU=8</td>
<td>STR=2</td>
</tr>
<tr>
<td>CLU=6, CLU=7, and CLU=8</td>
<td>3 – 1 = 2</td>
<td>CLU=4 and CLU=5</td>
</tr>
<tr>
<td>CLU=6, CLU=7, and CLU=8</td>
<td>3 – 1 = 2</td>
<td>2 – 1 = 1</td>
</tr>
</tbody>
</table>

Although there are three strata in the data set, STR=1 is an empty stratum for variable Y because of missing values and missing weights. In addition, no observations in stratum STR=3 belong to domain D=9. Therefore, STR=3 becomes an empty stratum as well for variable Y in domain D=9. As a result, the total number of non-empty strata for domain D=9 is one. The non-empty stratum for domain D=9 and variable Y is stratum STR=2. The total number of clusters for domain D=9 is two, which belong to stratum STR=2. Thus, for variable Y in domain D=9, the degrees of freedom for the t tests of the domain mean is df = 2 – 1 = 1. Similarly, for domain D=7, strata STR=1 and STR=2 are both empty strata, so the total number of strata is one (STR=3), and the total number of clusters is three (CLU=6, CLU=7, and CLU=8). Table 70.2 illustrates how domains affect the total number of clusters and total number of strata in the df calculation. Figure 70.8 shows the df computed by the procedure.

Output

Output Data Sets

Output data sets from PROC SURVEYMEANS are produced using ODS (Output Delivery System). ODS encompasses more than just the production of output data sets. For example, you can use ODS to manipulate the format of your output, the headers and titles of the tables, and the order of the columns in a table. For a more detailed description on using ODS, see Chapter 14, “Using the Output Delivery System.”

Displayed Output

By default PROC SURVEYMEANS displays a “Data Summary” table and a “Statistics” table. If you specify CLASS variables, or if you specify any character variables in the VAR statement, then the procedure displays a “Class Level Information” table. If you specify the LIST option in the STRATA statement, then the procedure displays a “Stratum Information” table. If you have a DOMAIN statement,
the procedure displays a “Domain Analysis” table. If you have a RATIO statement, the procedure displays a “Ratio Analysis” table.

**Data and Sample Design Summary**

The “Data Summary” table provides information on the input data set and the sample design. This table displays the total number of valid observations, where an observation is considered *valid* if it has nonmissing values for all procedure variables other than the analysis variables; that is, for all specified STRATA, CLUSTER, and WEIGHT variables. This number may differ from the number of nonmissing observations for an individual analysis variable, which the procedure displays in the “Statistics” table. See the section “Missing Values” on page 4333 for more information.

PROC SURVEYMEANS displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a STRATA statement
- Number of Clusters, if you specify a CLUSTER statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a WEIGHT statement

**Class Level Information**

If you use a CLASS statement to name classification variables for categorical analysis, or if you list any character variables in the VAR statement, then PROC SURVEYMEANS displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

**Stratum Information**

If you specify the LIST option in the STRATA statement, PROC SURVEYMEANS displays a “Stratum Information” table. This table displays the number of valid observations in each stratum, as well as the number of nonmissing stratum observations for each analysis variable. The “Stratum Information” table provides the following for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= option or the RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of valid observations in the stratum.
- N Obs, which is the number of valid observations
- Variable, which lists each analysis variable name
- Levels, which identifies each level for categorical variables
- N, which is the number of nonmissing observations for the analysis variable
- Clusters, which is the number of clusters, if you specify a CLUSTER statement

Statistics

The “Statistics” table displays all of the statistics that you request with statistic-keywords described on page 4326 in the PROC SURVEYMEANS statement. If you do not specify any statistic-keywords, then by default this table displays the following information for each analysis variable: the sample size, the mean, the standard error of the mean, and the confidence limits for the mean. The “Statistics” table may contain the following information for each analysis variable, depending on which statistic-keywords you request:

- Variable name
- Level, which identifies each level for categorical variables
- N, which is the number of nonmissing observations
- N Miss, which is the number of missing observations
- Minimum
- Maximum
- Range
- Number of Clusters
- Sum of Weights
- DF, which is the degrees of freedom for the $t$ test
- Mean
- Std Error of Mean, which is the standard error of the mean
- Var of Mean, which is the variance of the mean
- $t$ Value, for testing $H_0 : \text{population MEAN} = 0$
- $\Pr > |t|$, which is the two-sided $p$-value for the $t$ test
- $100(1 - \alpha)\%$ CL for Mean, which are two-sided confidence limits for the mean
- $100(1 - \alpha)\%$ Upper CL for Mean, which are one-sided upper confidence limits for the mean
- $100(1 - \alpha)\%$ Lower CL for Mean, which are one-sided lower confidence limits for the mean
• Coeff of Variation, which is the coefficients of variation for the mean and the sum
• Sum
• Std Dev, which is the standard deviation of the sum
• Var of Sum, which is the variance of the sum
• $100(1 - \alpha)\%$ CL for Sum, which are two-sided confidence limits for the sum
• $100(1 - \alpha)\%$ Upper CL for Sum, which are one-sided upper confidence limits for the sum
• $100(1 - \alpha)\%$ Lower CL for Sum, which are one-sided lower confidence limits for the Sum

**Domain Analysis**

If you use a DOMAIN statement, the procedure displays statistics in each domain in a “Domain Analysis” table. A “Domain Analysis” table contains all the columns in the “Statistics” table, plus columns of domain variable values.

Note that depending on how you define the domains with domain variables, the procedure may produce more than one “Domain Analysis” table. For example, in the following DOMAIN statement

```plaintext
domain A B*C*D A*C C;
```

you use four definitions to define domains:

• A: all the levels of A
• C: all the levels of C
• A*C: all the interactive levels of A and C
• B*C*D: all the interactive levels of B, C, and D

The procedure displays four “Domain Analysis” tables, one for each domain definition. However, if you use ODS output statement to create an output data set for domain analysis, the output data set contains a variable Domain whose values are these domain definitions.

**Ratio Analysis**

The “Ratio Analysis” table displays all of the statistics that you request with statistic-keywords in the PROC statement described on page 4326. If you do not specify any statistic-keywords, then by default this table displays the ratio and its standard error. The “Ratio Analysis” table may contain the following information for each ratio, depending on which statistic-keywords you request:

• Numerator, which identifies the numerator variable of the ratio
• Denominator, which identifies the denominator variable of the ratio
• N, which is the number of observations used in the ratio analysis
• number of Clusters
• Sum of Weights
• DF, which is the degrees of freedom for the t test
• Ratio
• Std Error of Ratio, which is the standard error of the ratio
• Var of Ratio, which is the variance of the ratio
• $t$ Value, for testing $H_0: \text{population Ratio} = 0$
• Pr $>|t|$, which is the two-sided p-value for the $t$ test
• $100(1-\alpha)\%$ CL for Ratio, which are two-sided confidence limits for the Ratio
• Upper $100(1-\alpha)\%$ CL for Ratio, which are one-sided upper confidence limits for the Ratio
• Lower $100(1-\alpha)\%$ CL for Ratio, which are one-sided lower confidence limits for the Ratio

When you use the ODS output statement to create an output data set, if you use labels for your RATIO statement, these labels are saved in a variable Ratio Statement in the output data set.

**ODS Table Names**

PROC SURVEYMEANS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

<table>
<thead>
<tr>
<th>ODS Table Name</th>

</table>

For example, the following statements create an output data set named MyStrata, which contains the “StrataInfo” table, and an output data set named MyStat, which contains the “Statistics” table for the ice cream study discussed in the section “Stratified Sampling” on page 4318:

```r
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Simple Random Sample Design';
proc surveymeans data=IceCream total=StudentTotals;
    strata Grade / list;
```
Chapter 70. The SURVEYMEANS Procedure

```
var Spending Group;
weight Weight;
ods output StrataInfo = MyStrata
   Statistics = MyStat;
run;
```

Examples

The “Getting Started” section on page 4315 contains examples of analyzing data from simple random sampling and stratified simple random sample designs. This section provides more examples that illustrate how to use PROC SURVEYMEANS.

Example 70.1. Stratified Cluster Sample Design

Consider the example in the section “Stratified Sampling” on page 4318. The study population is a junior high school with a total of 4,000 students in grades 7, 8, and 9. Researchers want to know how much these students spend weekly for ice cream, on the average, and what percentage of students spend at least $10 weekly for ice cream.

The example in the section “Stratified Sampling” on page 4318 assumes that the sample of students was selected using a stratified simple random sample design. This example shows analysis based on a more complex sample design.

Suppose that every student belongs to a study group and that study groups are formed within each grade level. Each study group contains between two and four students. Table 70.4 shows the total number of study groups for each grade.

<table>
<thead>
<tr>
<th>Grade</th>
<th>Number of Study Groups</th>
<th>Number of Students</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>608</td>
<td>1,824</td>
</tr>
<tr>
<td>8</td>
<td>252</td>
<td>1,025</td>
</tr>
<tr>
<td>9</td>
<td>403</td>
<td>1,151</td>
</tr>
<tr>
<td>Total</td>
<td>617</td>
<td>4,000</td>
</tr>
</tbody>
</table>

It is quicker and more convenient to collect data from students in the same study group than to collect data from students individually. Therefore, this study uses a stratified clustered sample design. The primary sampling units, or clusters, are study groups. The list of all study groups in the school is stratified by grade level. From each grade level, a sample of study groups is randomly selected, and all students in each selected study group are interviewed. The sample consists of eight study groups from the 7th grade, three groups from the 8th grade, and five groups from the 9th grade.

The SAS data set named IceCreamStudy saves the responses of the selected students:

```
data IceCreamStudy;
   input Grade StudyGroup Spending @@;
   if (Spending < 10) then Group='less';
   else Group='more';
```
In the data set *IceCreamStudy*, the variable *Grade* contain a student’s grade. The variable *StudyGroup* identifies a student’s study group. It is possible for students from different grades to have the same study group number because study groups are sequentially numbered within each grade. The variable *Spending* contains a student’s response to how much he spends per week for ice cream, in dollars. The variable *GROUP* indicates whether a student spends at least $10 weekly for ice cream. It is not necessary to store the data in order of grade and study group.

The SAS data set *StudyGroup* is created to provide PROC SURVEYMEANS with the sample design information shown in Table 70.4:

```sas
data StudyGroups;
  input Grade _total_; datalines;
    7 608
    8 252
    9 403;
;
```

The variable *Grade* identifies the strata, and the variable *_TOTAL_* contains the total number of study groups in each stratum. As discussed in the section “Specification of Population Totals and Sampling Rates” on page 4334, the population totals stored in the variable *_TOTAL_* should be expressed in terms of the primary sampling units (PSUs), which are study groups in this example. Therefore, the variable *_TOTAL_* contains the total number of study groups for each grade, rather than the total number of students.

In order to obtain unbiased estimates, you create sampling weights using the following SAS statements:

```sas
data IceCreamStudy;
  set IceCreamStudy;
  if Grade=7 then Prob=8/608;
  if Grade=8 then Prob=3/252;
  if Grade=9 then Prob=5/403;
  Weight=1/Prob;
;
```

The sampling weights are the reciprocals of the probabilities of selections. The variable *Weight* contains the sampling weights. Because the sampling design is
clustered, and all students from each selected cluster are interviewed, the sampling weights equal the inverse of the cluster (or study group) selection probabilities.

The following SAS statements perform the analysis for this sample design:

```sas
title1 'Analysis of Ice Cream Spending';
title2 'Stratified Clustered Sample Design';
proc surveymeans data=IceCreamStudy total=StudyGroups;
  strata Grade / list;
  cluster StudyGroup;
  var Spending Group;
  weight Weight;
run;
```

**Output 70.1.1.** Data Summary and Class Information

```
<table>
<thead>
<tr>
<th>Analysis of Ice Cream Spending</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stratified Clustered Sample Design</td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td>Variable</td>
</tr>
<tr>
<td>Levels</td>
</tr>
<tr>
<td>Values</td>
</tr>
<tr>
<td>Group</td>
</tr>
</tbody>
</table>
```

Output 70.1.1 provides information on the sample design and the input data set. There are 3 strata in the sample design, and the sample contains 16 clusters and 40 observations. The variable Group has two levels, ‘less’ and ‘more’.
Output 70.1.2 displays information for each stratum. Since the primary sampling units in this design are study groups, the population totals shown in Output 70.1.2 are the total numbers of study groups for each stratum or grade. This differs from Figure 70.3 on page 4320, which provides the population totals in terms of students since students were the primary sampling units for that design. Output 70.1.2 also displays the number of clusters for each stratum and analysis variable.
Output 70.1.3. Statistics

</table>

Output 70.1.3 displays the estimates of the average weekly ice cream expense and the percentage of students spending at least $10 weekly for ice cream.

Example 70.2. Domain Analysis

Suppose that you are studying profiles of the 800 top-performing companies to provide information on their impact on the economy. You are also interested in the company profiles within each market type. A sample of 66 companies is selected with unequal probability across market types. However, market type is not included in the sample design. Thus, the number of companies within each market type is a random variable in your sample. To obtain statistics within each market type, you should use domain analysis. The data of the 66 companies are saved in the following data set:

data Company;
  length Type $14;
  input Type$ Asset Sale Value Profit Employee Weight;
  datalines;

</table>
For each company in your sample,

- the variable \textit{Type} identifies the type of market for the company.
- the variable \textit{Asset} contains the company’s assets in millions of dollars.
- the variable \textit{Sale} contains sales in millions of dollars.
- the variable \textit{Value} contains the market value of the company in millions of dollars.
- the variable \textit{Profit} contains the profit in millions of dollars.
- the variable \textit{Employee} stores the number of employees in thousands.
- the variable \textit{Weight} contains the sampling weight.

The following SAS statements use PROC \textsc{surveymeans} to perform the domain analysis, estimating means and other statistics for the overall population and also for the subpopulations (or domain) defined by market type. The \textsc{domain} statement specifies \textit{Type} as the domain variable:

```sas
   title1 'Top Companies Profile Study';
   proc surveymeans data=Company total=800 mean sum;
     var Asset Sale Value Profit Employee;
     weight Weight;
     domain Type;
   run;
```

\textbf{Output 70.2.1.} Company Profile Study

\begin{tabular}{lrrrrr}
\hline
\textbf{Variable} & \textbf{Mean} & \textbf{Std Error} & \textbf{Sum} & \textbf{Std Dev} \\
\hline
\textit{Asset} & 6523.488510 & 720.557075 & 5217486 & 1073829 \\
\textit{Sale} & 4215.995799 & 839.132506 & 3371953 & 847885 \\
\textit{Value} & 2145.935121 & 342.531720 & 1716319 & 359609 \\
\textit{Profit} & 188.788210 & 25.057876 & 150993 & 30144 \\
\textit{Employee} & 36.874869 & 7.787857 & 29493 & 7148.003298 \\
\hline
\end{tabular}
Output 70.2.1 shows that there are 66 observations in the sample. The sum of the sampling weights equals 799.8, which is close to the total number of companies in the study population.

The “Statistics” table in Output 70.2.1 displays the estimates of the mean and total for all analysis variables for the entire 800 companies, while Output 70.2.2 shows the mean and total estimates for each company type.

Output 70.2.2. Domain Analysis for Company Profile Study

Example 70.3. Ratio Analysis

Suppose you are interested in the profit per employee and the sale per employee among the 800 top-performing companies in the data in the previous example. The following SAS statements illustrate how you can use PROC SURVEYMEANS to estimate these ratios:

```sas
title1 'Ratio Analysis in Top Companies Profile Study';
proc surveymeans data=Company total=800 ratio;
   var Profit Sale Employee;
   weight Weight;
   ratio Profit Sale / Employee;
run;
```

The RATIO statement requests the ratio of the profit and the sale to the number of employees.

Output 70.3.1. Estimate Ratios

<table>
<thead>
<tr>
<th>Numerator</th>
<th>Denominator</th>
<th>Ratio</th>
<th>Std Err</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sale</td>
<td>Employee</td>
<td>114.332497</td>
<td>20.502742</td>
</tr>
<tr>
<td>Profit</td>
<td>Employee</td>
<td>5.119698</td>
<td>1.058939</td>
</tr>
</tbody>
</table>

Output 70.3.1 shows the estimated ratios and their standard errors. Because the profit and the sale figures are in millions of dollars, and the employee numbers in thousands, the profit per employee is estimated as $5,120 with a standard error of $1,059, and the sale per employee is $114,333 with a standard error of $20,503.

Example 70.4. Analyzing Survey Data with Missing Values

As described in the section “Missing Values” on page 4333, the SURVEYMEANS procedure excludes an observation from the analysis if it has a missing value for the analysis variable or a nonpositive value for the WEIGHT variable.

However, if there is evidence indicating that the nonrespondents are different from the respondents for your study, you can use the DOMAIN statement to compute descriptive statistics among respondents from your survey data without imputation for nonrespondents. Note that although the variance estimation for respondents takes into account the assumption that the study population consists of distinct groups of respondents and nonrespondents, the degrees of freedom will not adjust for the nonrespondents because they are deleted from the computation. As a result, there are fewer degrees of freedom and wider confidence limits in comparison to counting.
those nonrespondents for degrees of freedom. When the sample size and the number of respondents are large, the difference maybe ignored.

Consider the ice cream example in the section “Stratified Sampling” on page 4318. Suppose that some of the students failed to provide the amounts spent on ice cream, as shown in the following data set IceCream:

```sas
data IceCream;
    input Grade Spending @@;
datalines;
7 7 7 7 8 . 9 10 7 . 7 10 7 3 8 20 8 19 7 2
7 . 9 15 8 16 7 6 7 6 7 6 9 15 8 17 8 14 9 .
9 8 9 7 7 3 7 12 7 4 9 14 8 18 9 9 7 2 7 1
7 4 7 11 9 8 8 . 8 13 7 . 9 . 9 11 7 2 7 9
;
```

Considering the possibility that those students who didn’t respond spend differently than those students who did respond, you can create an indicator variable to identify the respondents and non-respondents with the following SAS DATA step statements:

```sas
data IceCream;
    set IceCream;
    if Spending=. then Indicator='Nonrespondent';
    else do;
        Indicator='Respondent';
        if (Spending < 10) then Group='less';
        else Group='more';
    end;
    if Grade=7 then Prob=20/1824;
    if Grade=8 then Prob=9/1025;
    if Grade=9 then Prob=11/1151;
    Weight=1/Prob;
```

The variable `Indicator` identifies a student in the data set as either a respondent or a nonrespondent. The variable `Group` specifies whether a student spent more than $10 among the respondents.

The following SAS statements produce the desired analysis:

```sas
title1 'Analysis of Ice Cream Spending';
proc surveymeans data=IceCream total=StudentTotals mean sum;
    strata Grade / list;
    var Spending Group;
    weight Weight;
    domain Indicator;
run;
```
Output 70.4.1. Analysis of Incomplete Ice Cream Data Excluding Observations with Missing Values

```

Chapter 71
The SURVEYREG Procedure
Overview

The SURVEYREG procedure performs regression analysis for sample survey data. This procedure can handle complex survey sample designs, including designs with stratification, clustering, and unequal weighting. The procedure fits linear models for survey data and computes regression coefficients and their variance-covariance matrix. The procedure also provides significance tests for the model effects and for any specified estimable linear functions of the model parameters. Using the regression model, the procedure can compute predicted values for the sample survey data.

PROC SURVEYREG computes the regression coefficient estimators by generalized least-squares estimation using element-wise regression. The procedure assumes that the regression coefficients are the same across strata and primary sampling units (PSUs). To estimate the variance-covariance matrix for the regression coefficients, PROC SURVEYREG uses the Taylor expansion theory for estimating sampling errors of estimators based on complex sample designs (Woodruff 1971; Fuller 1975; Särndal, Swenson, and Wretman 1992, Chapter 5 and Chapter 13). This method obtains a linear approximation for the estimator and then uses the variance estimator for this approximation to estimate the variance of the estimator itself.

PROC SURVEYREG uses the ODS (Output Delivery System) to place results in output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality.

Getting Started

This section demonstrates how you can use PROC SURVEYREG to perform a regression analysis for sample survey data. For a complete description of the usage of PROC SURVEYREG, see the section “Syntax” on page 4373. The “Examples” section on page 4395 provides more detailed examples that illustrate the applications of PROC SURVEYREG.

Simple Random Sampling

Suppose that, in a junior high school, there are a total of 4,000 students in grades 7, 8, and 9. You want to know how household income and the number of children in a household affect students’ average weekly spending for ice cream.

In order to answer this question, you draw a sample using simple random sampling from the student population in the junior high school. You randomly select 40 students and ask them their average weekly expenditure for ice cream, their household income, and the number of children in their household. The answers from the 40 students are saved as a SAS data set:
data IceCream;
   input Grade Spending Income Kids @@;
datalines;
7 7 39 2 7 7 38 1 8 12 47 1
9 10 47 4 7 1 34 4 7 10 43 2
7 3 44 4 8 20 60 3 8 19 57 4
7 2 35 2 7 2 36 1 9 15 51 1
8 16 53 1 7 6 37 4 7 6 41 2
7 6 39 2 9 15 50 4 8 17 57 3
8 14 46 2 9 8 41 2 9 8 41 1
9 7 47 3 7 3 39 3 7 12 50 2
7 4 43 4 9 14 46 3 8 18 58 4
9 9 44 3 7 2 37 1 7 1 37 2
7 4 44 2 7 11 42 2 9 8 41 2
8 10 42 2 8 13 46 1 7 2 40 3
9 6 45 1 9 11 45 4 7 2 36 1
7 9 46 1
;

In the data set IceCream, the variable Grade indicates a student’s grade. The variable Spending contains the dollar amount of each student’s average weekly spending for ice cream. The variable Income specifies the household income, in thousands of dollars. The variable Kids indicates how many children are in a student’s family.

The following PROC SURVEYREG statements request a regression analysis:

```
title1 'Ice Cream Spending Analysis';
title2 'Simple Random Sample Design';
proc surveyreg data=IceCream total=4000;
   class Kids;
   model Spending = Income Kids / solution anova;
run;
```

The PROC SURVEYREG statement invokes the procedure. The TOTAL=4000 option specifies the total in the population from which the sample is drawn. The CLASS statement requests that the procedure use the variable Kids as a classification variable in the analysis. The MODEL statement describes the linear model that you want to fit, with Spending as the dependent variable and Income and Kids as the independent variables. The SOLUTION option in the MODEL statement requests that the procedure output the regression coefficient estimates. The ANOVA option requests that the procedure output the ANOVA table.

Figure 71.2. Testing Effects in the Regression

Figure 71.2 displays the ANOVA table for the regression and the tests for model
effects. The effect `Income` is significant in the linear regression model, while the effect `Kids` is not significant at the 5% level.

**Ice Cream Spending Analysis**

**Simple Random Sample Design**

The `SURVEYREG` Procedure

**Regression Analysis for Dependent Variable Spending**

**Estimated Regression Coefficients**

| Parameter    | Estimate | Standard Error | t Value | Pr > |t| |
|--------------|----------|----------------|---------|------|---|
| Intercept    | -26.08477 | 2.46720403     | -10.57  | <.0001 |
| Income       | 0.775330  | 0.04304415     | 18.01   | <.0001 |
| Kids 1       | 0.897655  | 1.12352876     | 0.80    | 0.4292 |
| Kids 2       | 1.494032  | 1.24705263     | 1.20    | 0.2381 |
| Kids 3       | -0.513181 | 1.33454891     | -0.38   | 0.7027 |
| Kids 4       | 0.000000  | 0.00000000     | .       | .     |

**NOTE:** The denominator degrees of freedom for the $t$ tests is 39. Matrix $X'X$ is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

**Figure 71.3.** Regression Coefficients

The regression coefficient estimates and their standard errors and associated $t$ tests are displayed in Figure 71.3.

### Stratified Sampling

Suppose that the previous student sample is actually drawn using a stratified sample design. The strata are grades in the junior high school: 7, 8, and 9. Within strata, simple random samples are selected. Table 71.1 provides the number of students in each grade.

**Table 71.1.** Students in Grades

<table>
<thead>
<tr>
<th>Grade</th>
<th>Number of Students</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>1,824</td>
</tr>
<tr>
<td>8</td>
<td>1,025</td>
</tr>
<tr>
<td>9</td>
<td>1,151</td>
</tr>
<tr>
<td>Total</td>
<td>4,000</td>
</tr>
</tbody>
</table>

In order to analyze this sample using PROC `SURVEYREG`, you need to input the stratification information by creating a SAS data set with the information in Table 71.1. The following SAS statements create such a data set called `StudentTotals`:

```sas
data StudentTotals;
  input Grade _TOTAL_;
datalines;
7 1824
```
The variable Grade is the stratification variable, and the variable \_TOTAL\_ contains the total numbers of students in each stratum in the survey population. PROC SURVEYREG requires you to use the keyword \_TOTAL\_ as the name of the variable that contains the population total information.

In a stratified sample design, when the sampling rates in the strata are unequal, you need to use sampling weights to reflect this information. For this example, the appropriate sampling weights are the reciprocals of the probabilities of selection. You can use the following data step to create the sampling weights:

```plaintext
data IceCream;
  set IceCream;
  if Grade=7 then Prob=20/1824;
  if Grade=8 then Prob=9/1025;
  if Grade=9 then Prob=11/1151;
  Weight=1/Prob;
run;
```

If you use PROC SURVEYSELECT to select your sample, PROC SURVEYSELECT creates these sampling weights for you.

The following statements demonstrate how you can fit a linear model while incorporating the sample design information (stratification):

```plaintext
title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution anova;
  weight Weight;
run;
```

Comparing these statements to those in the section “Simple Random Sampling” on page 4365, you can see how the TOTAL=StudentTotals option replaces the previous TOTAL=4000 option.

The STRATA statement specifies the stratification variable Grade. The LIST option in the STRATA statement requests that the stratification information be included in the output. The WEIGHT statement specifies the weight variable.
Figure 71.4. Summary of the Regression

Figure 71.4 summarizes the data information, the sample design information, and the fit information. Note that, due to the stratification, the denominator degrees of freedom for $F$ tests and $t$ tests is 37, which is different from the analysis in Figure 71.1.

Figure 71.5. Stratification and Classification Information
For each stratum, Figure 71.5 displays the value of identifying variables, the number of observations (sample size), the total population size, and the calculated sampling rate or fraction.

**Estimated Regression Coefficients**  

| Parameter | Estimate | Standard Error | t Value | Pr > |t| |
|-----------|----------|----------------|---------|------|---|
| Intercept | -26.086882 | 2.44108058 | -10.69 | <.0001 |
| Income    | 0.776699  | 0.04295904 | 18.08  | <.0001 |
| Kids 1    | 0.888631  | 1.07000634 | 0.83   | 0.4116 |
| Kids 2    | 1.545726  | 1.20815863 | 1.28   | 0.2087 |
| Kids 3    | -0.526817 | 1.32748011 | -0.40  | 0.6938 |
| Kids 4    | 0.000000  | 0.00000000 | .      | .    |

NOTE: The denominator degrees of freedom for the t tests is 37. Matrix X'WX is singular and a generalized inverse was used to solve the normal equations. Estimates are not unique.

**Figure 71.7. Regression Coefficients**

The regression coefficient estimates for the stratified sample, along with their standard errors and associated t tests, are displayed in Figure 71.7.
You can request other statistics and tests using PROC SURVEYREG. You can also analyze data from a more complex sample design. The remainder of this chapter provides more detailed information.

**Output Data Set**

PROC SURVEYREG uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

For example, to save the “ParameterEstimates” table (Figure 71.7) in the previous section in an output data set, you use the ODS OUTPUT statement as follows:

```sas
title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
  strata Grade /list;
  class Kids;
  model Spending = Income Kids / solution;
  weight Weight;
  ods output ParameterEstimates = MyParmEst;
run;
```

The statement

```sas
ods output ParameterEstimates = MyParmEst;
```

requests that the “ParameterEstimates” table that appears in Figure 71.7 be placed in a SAS data set named `MyParmEst`.

The PRINT procedure displays observations of the data set `MyParmEst`:

```sas
proc print data=MyParmEst;
run;
```

Figure 71.8 displays the observations in the data set `MyParmEst`.

![Figure 71.8](image)

---

**Figure 71.8.** The Data Set MyParmEst
The section “ODS Table Names” on page 4394 gives the complete list of the tables produced by PROC SURVEYREG.

Syntax

The following statements are available in PROC SURVEYREG:

```
PROC SURVEYREG < options > ;
    BY variables ;
    CLASS variables ;
    CONTRAST 'label' effect values
          < ... effect values > < / options > ;
    ESTIMATE 'label' effect values
           < ... effect values > < / options > ;
    MODEL dependent = < effects > < / options > ;
    STRATA variables < / options > ;
    WEIGHT variable ;
```

The PROC SURVEYREG and MODEL statements are required. If your model contains classification effects, you must list the classification variables in a CLASS statement, and the CLASS statement must precede the MODEL statement. If you use a CONTRAST statement or an ESTIMATE statement, the MODEL statement must precede the CONTRAST or ESTIMATE statement.

The CLASS, CLUSTER, STRATA, CONTRAST, and ESTIMATE statements can appear multiple times. You should only use one MODEL statement and one WEIGHT statement.

PROC SURVEYREG Statement

```
PROC SURVEYREG < options > ;
```

The PROC SURVEYREG statement invokes the procedure. You can specify the following options in the PROC SURVEYREG statement:

**ALPHA=**α

sets the confidence level for confidence limits. The value of the ALPHA= option must be between 0 and 1, and the default value is 0.05. A confidence level of α produces 100(1 − α)% confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

**DATA=**SAS-data-set

specifies the SAS data set to be analyzed by PROC SURVEYREG. If you omit the DATA= option, the procedure uses the most recently created SAS data set.
specifies the sampling rate as a non-negative value, or specifies an input data set that contains the stratum sampling rates. The procedure uses this information to compute a finite population correction for variance estimation. If your sample design has multiple stages, you should specify the first-stage sampling rate, which is the ratio of the number of PSUs selected to the total number of PSUs in the population. For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a non-negative value for the RATE= option. If your design is stratified with different sampling rates in the strata, then you should name a SAS data set that contains the stratification variables and the sampling rates. See the section Specification of Population Totals and Sampling Rates on page 4382 for more details.

The value in the RATE= option or the values of RATE in the secondary data set must be non-negative numbers. You can specify value as a number between 0 and 1. Or you can specify value in percentage form as a number between 1 and 100, and PROC SURVEYREG will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

specifies the total number of primary sampling units in the study population as a positive value, or specifies an input data set that contains the stratum population totals. The procedure uses this information to compute a finite population correction for variance estimation.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive value for the TOTAL= option. If your sample design is stratified with different population totals in the strata, then you should name a SAS data set that contains the stratification variables and the population totals. See the section Specification of Population Totals and Sampling Rates on page 4382 for more details.

If you do not specify the TOTAL= option or the RATE= option, then the variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option.

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of the CLASS, STRATA, and CLUSTER variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to Version 9.
BY Statement

    BY variables ;

You can specify a BY statement with PROC SURVEYREG to obtain separate analyses on observations in groups defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid subpopulation or domain analysis, where the total number of units in the subpopulation is not known with certainty. For more information on subpopulation analysis for sample survey data, refer to Cochran (1977).

When a BY statement appears, the procedure expects the input data sets to be sorted in order of the BY variables. If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the SURVEYREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

CLASS Statement

    CLASS | CLASSES variables ;

The CLASS statement specifies the classification variables to be used in the model. Typical class variables are TREATMENT, GENDER, RACE, GROUP, and REPLICA TION. If you specify the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Concepts. By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. In releases prior to Version 9, class levels were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this
previous behavior you can use the TRUNCATE option in the PROC SURVEYREG statement.

You can use multiple CLASS statements to specify classification variables.

CLUSTER Statement

```
CLUSTER | CLUSTERS  variables ;
```

The CLUSTER statement specifies variables that identify clusters in a clustered sample design. The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should identify only the first-stage clusters, or primary sampling units (PSUs), in the CLUSTER statement.

The CLUSTER variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide and to the discussions of the FORMAT statement and SAS formats in SAS Language Reference: Dictionary. By default, clusters are determined from the entire formatted values of the CLUSTER variables. Note that this represents a slight change from previous releases in the way in which clusters are determined. In releases prior to Version 9, clusters were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the TRUNCATE option in the PROC SURVEYREG statement.

You can use multiple CLUSTER statements to specify cluster variables. The procedure uses variables from all CLUSTER statements to create clusters.

CONTRAST Statement

```
CONTRAST 'label' effect values < / options > ;
```

```
CONTRAST 'label' effect values < . . . effect values > < / options > ;
```

The CONTRAST statement provides custom hypothesis tests for linear combinations of the regression parameters \( H_0: L\beta = 0 \), where \( L \) is the vector or matrix you specify and \( \beta \) is the vector of regression parameters. Thus, to use this feature, you must be familiar with the details of the model parameterization used by PROC SURVEYREG. For information on the parameterization, see the section “Parameterization of PROC GLM Models” on page 1787 in Chapter 32, “The GLM Procedure.”

Each term in the MODEL statement, called an effect, is a variable or a combination of variables. You can specify an effect with a variable name or a special notation using variable names and operators. For more details on how to specify an effect, see the section “Specification of Effects” on page 1784 in Chapter 32, “The GLM Procedure.”

For each CONTRAST statement, PROC SURVEYREG computes Wald’s F test. The procedure displays this value with the degrees of freedom, and identifies it with the
contrast label. The numerator degrees of freedom for Wald’s $F$ test equals $\text{rank}(L)$. The denominator degrees of freedom equals the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can use the DF= option in the MODEL statement to specify the denominator degrees of freedom.

You can specify any number of CONTRAST statements, but they must appear after the MODEL statement.

In the CONTRAST statement,

- `label` identifies the contrast in the output. A label is required for every contrast specified. Labels must be enclosed in single quotes.
- `effect` identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
- `values` are constants that are elements of $L$ associated with the effect.

You can specify the following options in the CONTRAST statement after a slash (/):

- **E**
  - displays the entire coefficient $L$ vector or matrix.

- **NOFILL**
  - requests no filling in higher-order effects. When you specify only certain portions of $L$, by default PROC SURVEYREG constructs the remaining elements from the context. (For more information, see the section “Specification of ESTIMATE Expressions” on page 1801 in Chapter 32, “The GLM Procedure.”)

When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector or matrix $L$ as it is defined in the CONTRAST statement.

- **SINGULAR=value**
  - specifies the sensitivity for checking estimability. If $v$ is a vector, define $\text{ABS}(v)$ to be the largest absolute value of the elements of $v$. Say $H$ is the $(X'X)^{-1}X'X$ matrix, and $C$ is $\text{ABS}(L)$ except for elements of $L$ that equal 0, and then $C$ is 1. If $\text{ABS}(L - LH) > C \cdot \text{value}$, then $L$ is declared nonestimable. The SINGULAR= value must be between 0 and 1, and the default is $10^{-4}$.

As stated previously, the CONTRAST statement enables you to perform hypothesis tests $H_0: L\beta = 0$.

If the $L$ matrix contains more than one contrast, then you can separate the rows of the $L$ matrix with commas. For example, for the model

```plaintext
proc surveyreg;
  class A B;
  model Y=A B;
run;
```
with \( A \) at 5 levels and \( B \) at 2 levels, the parameter vector is

\[
(\mu \ \alpha_1 \ \alpha_2 \ \alpha_3 \ \alpha_4 \ \alpha_5 \ \beta_1 \ \beta_2)
\]

To test the hypothesis that the pooled \( A \) linear and \( A \) quadratic effect is zero, you can use the following \( L \) matrix:

\[
L = \begin{bmatrix}
0 & -2 & -1 & 0 & 1 & 2 & 0 & 0 \\
0 & 2 & -1 & -2 & -1 & 2 & 0 & 0
\end{bmatrix}
\]

The corresponding CONTRAST statement is

```plaintext
contrast 'A Linear & Quadratic'
  a -2 -1 0 1 2,
  a 2 -1 -2 -1 2;
```

**ESTIMATE Statement**

```plaintext
ESTIMATE 'label' effect values < / options >;
ESTIMATE 'label' effect values < . . . effect values > < / options >;
```

You can use an ESTIMATE statement to estimate a linear function of the regression parameters by multiplying a row vector \( L \) by the parameter estimate vector \( \hat{\beta} \).

Each term in the MODEL statement, called an effect, is a variable or a combination of variables. You can specify an effect with a variable name or with a special notation using variable names and operators. For more details on how to specify an effect, see the section “Specification of Effects” on page 1784 in Chapter 32, “The GLM Procedure.”

PROC SURVEYREG checks the linear function for estimability. (See the SINGULAR= option described on page 4379).

The procedure displays the estimate \( L\hat{\beta} \) along with its standard error and \( t \) test. If you specify the CLPARM option in the MODEL statement, PROC SURVEYREG also displays confidence limits for the linear function. By default, the degrees of freedom for the \( t \) test equals the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of strata. Alternatively, you can specify the degrees of freedom with the DF= option in the MODEL statement.

You can specify any number of ESTIMATE statements, but they must appear after the MODEL statement.

In the ESTIMATE statement,

- `label` identifies the linear function \( L \) in the output. A label is required for every function specified. Labels must be enclosed in single quotes.
- `effect` identifies an effect that appears in the MODEL statement. You can use the INTERCEPT keyword as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the MODEL statement.
values values are constants that are elements of the vector \( L \) associated with the effect. For example, the following code forms an estimate that is the difference between the parameters estimated for the first and second levels of the CLASS variable \( A \).

\[
\text{estimate } 'A1 \text{ vs } A2' \ A \ 1 \ -1;
\]

You can specify the following options in the ESTIMATE statement after a slash (/):

- **DIVISOR=value**
  specifies a value by which to divide all coefficients so that fractional coefficients can be entered as integers. For example, you can use

\[
\text{estimate } '1/3(A1+A2) - 2/3A3' \ a \ 1 \ 1 \ -2 / \text{divisor}=3;
\]

  instead of

\[
\text{estimate } '1/3(A1+A2) - 2/3A3' \ a \ 0.33333 \ 0.33333 \ -0.66667;
\]

- **E**
  displays the entire coefficient vector \( L \).

- **NOFILL**
  requests no filling in higher-order effects. When you specify only certain portions of the vector \( L \), by default PROC SURVEYREG constructs the remaining elements from the context. (See the section “Specification of ESTIMATE Expressions” on page 1801 in Chapter 32, “The GLM Procedure.”) When you specify the NOFILL option, PROC SURVEYREG does not construct the remaining portions and treats the vector \( L \) as it is defined in the ESTIMATE statement.

- **SINGULAR=value**
  specifies the sensitivity for checking estimability. If \( v \) is a vector, define \( \text{ABS}(v) \) to be the largest absolute value of the elements of \( v \). Say \( H \) is the \((X'X)^{-1}X'X\) matrix, and \( C \) is \( \text{ABS}(L) \) except for elements of \( L \) that equal 0, and then \( C \) is 1. If \( \text{ABS}(L - LH) > C \times \text{value} \), then \( L \) is declared nonestimable. The SINGULAR= value must be between 0 and 1, and the default is \( 10^{-4} \).

---

**MODEL Statement**

\[
\text{MODEL } \text{dependent} = < \text{effects} > / < \text{options} >;
\]

The MODEL statement specifies the dependent (response) variable and the independent (regressor) variables or effects. Each term in a MODEL statement, called an effect, is a variable or a combination of variables. You can specify an effect with a variable name or with special notation using variable names and operators. For more information on how to specify an effect, see the section “Specification of Effects” on page 1784 in Chapter 32, “The GLM Procedure.” The dependent variable must be numeric. Only one MODEL statement is allowed for each PROC SURVEYREG
statement. If you specify more than one MODEL statement, the procedure uses the first model and ignores the rest.

You can specify the following options in the MODEL statement after a slash (/):

**ADJRSQ**

requests the procedure to compute the adjusted multiple R-square.

**ANOVA**

requests the ANOVA table to be produced in the output. By default, the ANOVA table will not be printed in the output.

**CLPARM**

requests confidence limits for the parameter estimates. The SURVEYREG procedure determines the confidence coefficient using the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence bounds. The CLPARM option also requests confidence limits for all the estimable linear functions of regression parameters in the ESTIMATE statements.

Note that when there is a CLASS statement, you need to use the `SOLUTION` option with the CLPARM option to obtain the parameter estimates and their confidence limits.

**COVB**

displays the estimated covariance matrix of the estimated regression estimates.

**DEFF**

displays design effects for the regression coefficient estimates.

**DF=value**

specifies the denominator degrees of freedom for the $F$ tests and the degrees of freedom for the $t$ tests. The default is the number of clusters (or the number of observations if there is no CLUSTER statement) minus the number of actual strata. The number of actual strata equals the number of strata in the data before collapsing minus the number of strata collapsed plus 1. See the section “Stratum Collapse” on page 4388 for details on “collapsing of strata.”

**INVERSE**

displays the inverse or the generalized inverse of the $X'X$ matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the $X'WX$ matrix, where $W$ is the diagonal matrix constructed from WEIGHT variable values.

**NOINT**

omits the intercept from the model.

**SOLUTION**

displays a solution to the normal equations, which are the parameter estimates. The SOLUTION option is useful only when you use a CLASS statement. If you do not specify a CLASS statement, PROC SURVEYREG displays parameter estimates by default. But if you specify a CLASS statement, PROC SURVEYREG does not display parameter estimates unless you also specify the SOLUTION option.
**VADJUST=DF | NONE**

**VARADJ=DF | NONE**

**VARADJUST=DF | NONE**

specifies if the you want to use degrees of freedom adjustment \( \frac{(n - 1)}{(n - p)} \) in the computation of the matrix \( G \) for the variance estimation on page 4385. If you do not specify the VADJUST= option, by default, PROC SURVEYREG uses the degrees of freedom adjustment, that is equivalent to the VARADJ=DF option. If you do not wish to use this variance adjustment, you can specify the VADJUST=NONE option.

**X**

**XPX**

displays the \( X'X \) matrix, or the \( X'WX \) matrix when there is a WEIGHT variable, where \( W \) is the diagonal matrix constructed from WEIGHT variable values. The X option also displays the crossproducts vector \( X'y \), or \( X'Wy \).

---

**STRATA Statement**

**STRATA | STRATUM**  

variables < /options> ;

The STRATA statement specifies variables that form the strata in a stratified sample design. The combinations of categories of STRATA variables define the strata in the sample.

If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement. See the section “Specification of Population Totals and Sampling Rates” on page 4382 for more information.

The STRATA variables are one or more variables in the DATA= input data set. These variables can be either character or numeric. By default, strata are determined from the entire formatted values of the STRATA variables. Note that this represents a slight change from previous releases in the way in which strata are determined. In releases prior to Version 9, strata were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the TRUNCATE option in the PROC SURVEYREG statement.

Thus, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide*.

You can use multiple STRATA statements to specify stratum variables.

You can specify the following options in the STRATA statement after a slash (/):

**LIST**

displays a “Stratum Information” table, which includes values of the STRATA variables, and the number of observations, number of clusters, population total, and sampling rate for each stratum. This table also displays stratum collapse information.

**NOCOLLAPSE**

prevents the procedure from collapsing, or combining, strata that have only one sampling unit. By default, the procedure collapses strata that contain only one sampling unit. See the section “Stratum Collapse” on page 4388 for details.
**WEIGHT Statement**

```plaintext
WEIGHT | WGT  variable ;
```

The WEIGHT statement specifies the variable that contains the sampling weights. This variable must be numeric. If you do not specify a WEIGHT statement, PROC SURVEYREG assigns all observations a weight of 1. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

**Details**

**Missing Values**

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYREG excludes that observation from the analysis. An observation is also excluded if it has a missing value for any STRATA variable, CLUSTER variable, dependent variable, or any variable used in the independent effects. The analysis includes all observations in the data set that have nonmissing values for all these design and analysis variables.

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. If the respondents are different from the nonrespondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. Once data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYREG. Refer to Cochran (1977) for more details.

**Survey Design Information**

**Specification of Population Totals and Sampling Rates**

If your analysis should include a finite population correction ($fpc$), you can input either the sampling rate or the population total using the RATE= option or the TOTAL= option. You cannot specify both of these options in the same PROC SURVEYREG statement. If you do not specify one of these options, the procedure does not use the $fpc$ when computing variance estimates. For fairly small sampling fractions, it is appropriate to ignore this correction. Refer to Cochran (1977) and Kish (1965).

If your design has multiple stages of selection and you are specifying the RATE= option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the TOTAL= option for a multistage design, you should input the total number of PSUs in the study population.
For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you should use the RATE=value option or the TOTAL=value option. If your sample design is stratified with different sampling rates or population totals in the strata, then you can use the RATE=SAS-data-set option or the TOTAL=SAS-data-set option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a secondary data set, as opposed to the primary data set that you specify with the DATA= option.

The secondary data set must contain all the stratification variables listed in the STRATA statement and all the variables in the BY statement. If there are formats associated with the STRATA variables and the BY variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the TOTAL=SAS-data-set option, the secondary data set must have a variable named _TOTAL_ that contains the stratum population totals. Or if you specify the RATE=SAS-data-set option, the secondary data set must have a variable named _RATE_ that contains the stratum sampling rates.

The secondary data set must contain all BY and STRATA groups that occur in the primary data set. If the secondary data set contains more than one observation for any one stratum, then the procedure uses the first value of _TOTAL_ or _RATE_ for that stratum and ignores the rest.

The value in the RATE= option, or the values of _RATE_ in the secondary data set, must be non-negative numbers. You can specify a sampling rate as a number between 0 and 1. Or you can specify a sampling rate in percentage form as a number between 1 and 100, and PROC SURVEYREG will convert that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you specify the TOTAL=value option, value must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

**Primary Sampling Units (PSUs)**

When you have clusters, or primary sampling units (PSUs), in your sample design, the procedure estimates variance from the variation among PSUs. For more information, see the section “Variance Estimation” on page 4385. You can use the CLUSTER statement to identify the first stage clusters in your design. PROC SURVEYREG assumes that each cluster represents a PSU in the sample and that each observation is an element of a PSU. If you do not specify a CLUSTER statement, the procedure treats each observation as a PSU.
Computational Details

Notation

For a stratified clustered sample design, observations are represented by an \( n \times (p+2) \) matrix

\[
(w, y, X) = (w_{hij}, y_{hij}, x_{hij})
\]

where

- \( w \) denotes the sampling weight vector
- \( y \) denotes the dependent variable
- \( X \) denotes the design matrix. (When an effect contains only classification variables, the columns of \( X \) corresponding to this effect contain only 0s and 1s; no reparameterization is made.)
- \( h = 1, 2, \ldots, H \) is the stratum number with a total of \( H \) strata
- \( i = 1, 2, \ldots, n_h \) is the cluster number within stratum \( h \), with a total of \( n_h \) clusters
- \( j = 1, 2, \ldots, m_{hi} \) is the unit number within cluster \( i \) of stratum \( h \), with a total of \( m_{hi} \) units
- \( p \) is the total number of parameters (including an intercept if the INTERCEPT effect is included in the MODEL statement)
- \( n = \sum_{h=1}^{H} \sum_{i=1}^{n_h} m_{hi} \) is the total number of observations in the sample

Also, \( f_h \) denotes the sampling rate for stratum \( h \). You can use the TOTAL= option or the RATE= option to input population totals or sampling rates. See the section “Specification of Population Totals and Sampling Rates” on page 4382 for details. If you input stratum totals, PROC SURVEYREG computes \( f_h \) as the ratio of the stratum sample size to the stratum total. If you input stratum sampling rates, PROC SURVEYREG uses these values directly for \( f_h \). If you do not specify the TOTAL= option or the RATE= option, then the procedure assumes that the stratum sampling rates \( f_h \) are negligible, and a finite population correction is not used when computing variances.

Regression Coefficients

PROC SURVEYREG solves the normal equations \( X'WX\beta = X'Wy \) using a modified sweep routine that produces a generalized (g2) inverse \((X'WX)^{-} \) and a solution (Pringle and Raynor 1971)

\[
\hat{\beta} = (X'WX)^{-}X'Wy
\]

where \( W \) is the diagonal matrix constructed from WEIGHT variable values.

For models with class variables, there are more design matrix columns than there are degrees of freedom (DF) for the effect. Thus, there are linear dependencies among the columns. In this case, the parameters are not estimable; there is an infinite number of
least-squares solutions. PROC SURVEYREG uses a generalized (g2) inverse to obtain values for the estimates. The solution values are not displayed unless you specify the SOLUTION option in the MODEL statement. The solution has the characteristic that estimates are 0 whenever the design column for that parameter is a linear combination of previous columns. (Strictly termed, the solution values should not be called estimates.) With this full parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

**Variance Estimation**

PROC SURVEYREG uses the Taylor series expansion theory to estimate the covariance-variance matrix of the estimated regression coefficients (Fuller 1975). Let

\[ r = y - X\hat{\beta} \]

where the \((h, i, j)\)th element is \(r_{hij}\). Compute 1 \(\times\) \(p\) row vectors

\[ e_{hi} = w_{hij}r_{hij}x_{hij} \]

\[ e_{h..} = \sum_{j=1}^{m_{hi}} e_{hij} \]

\[ \bar{e}_{h..} = \frac{1}{n_h} \sum_{i=1}^{n_h} e_{hi..} \]

and calculate the \(p \times p\) matrix

\[ G = \frac{n - 1}{n - p} \sum_{h=1}^{H} n_h \left(1 - f_h\right) \sum_{i=1}^{n_h} (e_{hi..} - \bar{e}_{h..})(e_{hi..} - \bar{e}_{h..})' \]

PROC SURVEYREG computes the covariance matrix of \(\beta\) as

\[ \hat{V} = (X'WX)^{-1} G (X'WX)^{-1} \]

The factor \((n - 1)/(n - p)\) in the computation of the matrix \(\hat{G}\) should reduce the small sample bias associated with using the estimated function to calculate deviations (Hidiroglou et al. (1980)). For simple random sampling, this factor contributes to the degrees of freedom correction applied to the residual mean square for ordinary least squares in which \(p\) parameter are estimated. By default, the procedure will use this adjustment in the variance estimation. It is equivalent to specify the VADJUST=DF option in the MODEL statement. If you do not wish to use this multiplier in the variance estimation, you can specify the VADJUST=NONE option in the MODEL statement to suppress this factor.

**Degrees of Freedom**

PROC SURVEYREG produces tests for the significance of model effects, regression parameters, estimable functions specified in the ESTIMATE statement, and contrasts specified in the CONTRAST statement. It computes all these tests taking into account the sample design. The degrees of freedom for these tests differ from the degrees of freedom for the ANOVA table, which does not consider the sample design.
Denominator Degrees of Freedom

The denominator DF refers to the denominator degrees of freedom for $F$ tests and to the degrees of freedom for $t$ tests in the analysis. By default, the denominator DF equals the number of clusters minus the actual number of strata. If there are no clusters, the denominator DF equals the number of observations minus the actual number of strata. The actual number of strata equals

- one, if there is no STRATA statement
- the number of strata in the sample, if there is a STRATA statement but the procedure does not collapse any strata
- the number of strata in the sample after collapsing, if there is a STRATA statement and the procedure collapses strata that have only one sampling unit

Alternatively, you can specify the denominator DF using the DF= option on page 4380 in the MODEL statement.

Numerator Degrees of Freedom

The numerator DF refers to the numerator degrees of freedom for the Wald $F$ statistic associated with an effect or with a contrast. The procedure computes the Wald $F$ statistic for an effect as a Type III test; that is, the test has the following properties:

- The hypothesis for an effect does not involve parameters of other effects except for containing effects (which it must involve to be estimable).
- The hypotheses to be tested are invariant to the ordering of effects in the model.

See the section “Testing Effects” on page 4386 for more information. The numerator DF for the Wald $F$ statistic for a contrast is the rank of the $L$ matrix that defines the contrast.

Testing Effects

For each effect in the model, PROC SURVEYREG computes an $L$ matrix such that every element of $L\beta$ is estimable; the $L$ matrix has the maximum possible rank associated with the effect. To test the effect, the procedure uses the Wald $F$ statistic for the hypothesis $H_0: L\beta = 0$. The Wald $F$ statistic equals

$$F_{\text{Wald}} = \frac{(L\hat{\beta})' (L'\hat{V}L)^{-1} (L\hat{\beta})}{\text{rank}(L)}$$

with numerator degrees of freedom equal to $\text{rank}(L)$ and denominator degrees of freedom equal to the number of clusters minus the number of strata (unless you have specified the denominator degrees of freedom with the DF= option in the MODEL statement; see the section “Denominator Degrees of Freedom” on page 4386). It is possible that the $L$ matrix cannot be constructed for an effect, in which case that effect is not testable. For more information on how the matrix $L$ is constructed, see the discussion in Chapter 11, “The Four Types of Estimable Functions.”
**Analysis of Variance (ANOVA)**

PROC SURVEYREG produces an analysis of variance table for the model specified in the **MODEL** statement. This table is identical to the one produced by the GLM procedure for the model. PROC SURVEYREG computes ANOVA table entries using the sampling weights, but not the sample design information on stratification and clustering.

The degrees of freedom (DF) displayed in the ANOVA table are the same as those in the ANOVA table produced by PROC GLM. The Total DF is the total degrees of freedom used to obtain the regression coefficient estimates. The Total DF equals the total number of observations minus 1 if the model includes an intercept. If the model does not include an intercept, the Total DF equals the total number of observations. The Model DF equals the degrees of freedom for the effects in the **MODEL** statement, not including the intercept. The Error DF equals the total DF minus the model DF.

**Multiple R-square**

PROC SURVEYREG computes a multiple R-square for the weighted regression as

\[ R^2 = 1 - \frac{SS_{error}}{SS_{total}} \]

where \( SS_{error} \) is the error sum of squares in the ANOVA table

\[ SS_{error} = r'W r \]

and \( SS_{total} \) is the total sum of squares

\[ SS_{total} = \begin{cases} y'y & \text{if no intercept} \\ y'y - \left( \sum_{h=1}^{H} \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} w_{hij} y_{hij} \right)^2 / w_{...} & \text{otherwise} \end{cases} \]

where \( w_{...} \) is the sum of the sampling weights over all observations.

**Adjusted R-square**

If you specify the option ADJRSQ in the **MODEL** statement, PROC SURVEYREG computes an multiple R-square adjusted as the weighted regression as

\[ ADJRSQ = \begin{cases} 1 - \frac{n(1 - R^2)}{n - p} & \text{if no intercept} \\ 1 - \frac{(n - 1)(1 - R^2)}{n - p} & \text{otherwise} \end{cases} \]

where \( R^2 \) is the multiple R-square.
**Root Mean Square Errors**

PROC SURVEYREG computes the square root of mean square errors as

\[ \sqrt{\text{MSE}} = \sqrt{n \frac{SS_{\text{error}}}{(n - p)} w} \]

where \( w \ldots \) is the sum of the sampling weights over all observations.

**Design Effect**

If you specify the DEFF option in the MODEL statement, PROC SURVEYREG calculates the design effects for the regression coefficients. The design effect of an estimate is the ratio of the actual variance to the variance computed under the assumption of simple random sampling.

\[ \text{DEFF} = \frac{\text{Variance under the Sample Design}}{\text{Variance under Simple Random Sampling}} \]

Refer to Kish (1965, p. 258). PROC SURVEYREG computes the numerator as described in the section “Variance Estimation” on page 4385. And the denominator is computed under the assumption that the sample design is simple random sampling, with no stratification and no clustering.

To compute the variance under the assumption of simple random sampling, PROC SURVEYREG calculates the sampling rate as follows. If you specify both sampling weights and sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is calculated as

\[ f_{\text{SRS}} = \frac{n}{w} \]

where \( n \) is the sample size and \( w \ldots \) (the sum of the weights over all observations) estimates the population size. If the sum of the weights is less than the sample size, \( f_{\text{SRS}} \) is set to zero. If you specify sampling rates for the analysis but not sampling weights, then PROC SURVEYREG computes the sampling rate under simple random sampling as the average of the stratum sampling rates.

\[ f_{\text{SRS}} = \frac{1}{H} \sum_{h=1}^{H} f_h \]

If you do not specify sampling rates (or population totals) for the analysis, then the sampling rate under simple random sampling is assumed to be zero.

\[ f_{\text{SRS}} = 0 \]

**Stratum Collapse**

If there is only one sampling unit in a stratum, then PROC SURVEYREG cannot estimate the variance for this stratum. To estimate stratum variances, by default the procedure collapses, or combines, those strata that contain only one sampling unit. If you specify the NOCOLLAPSE option in the STRATA statement, PROC SURVEYREG
Contrasts does not collapse strata and uses a variance estimate of 0 for any stratum that contains only one sampling unit.

If you do not specify the NOCOLLAPSE option, PROC SURVEYREG collapses strata according to the following rules. If there are multiple strata that each contain only one sampling unit, then the procedure collapses, or combines, all these strata into a new pooled stratum. If there is only one stratum with a single sampling unit, then PROC SURVEYREG collapses that stratum with the preceding stratum, where strata are ordered by the STRATA variable values. If the stratum with one sampling unit is the first stratum, then the procedure combines it with the following stratum.

If you specify stratum sampling rates using the RATE=SAS-data-set option, PROC SURVEYREG computes the sampling rate for the new pooled stratum as the weighted average of the sampling rates for the collapsed strata. See the section “Computational Details” on page 4384 for details. If the specified sampling rate equals 0 for any of the collapsed strata, then the pooled stratum is assigned a sampling rate of 0. If you specify stratum totals using the TOTAL=SAS-data-set option, PROC SURVEYREG combines the totals for the collapsed strata to compute the sampling rate for the new pooled stratum.

Sampling Rate of the Pooled Stratum from Collapse

Assuming that PROC SURVEYREG collapses single-unit strata $h_1, h_2, \ldots, h_c$ into the pooled stratum, the procedure calculates the sampling rate for the pooled stratum as

$$f_{\text{Pooled Stratum}} = \begin{cases} 0 & \text{if any of } f_{h_l} = 0 \text{ where } l = 1, 2, \ldots, c \\ \left( \sum_{l=1}^{c} n_{h_l} f_{h_l}^{-1} \right)^{-1} \sum_{l=1}^{c} n_{h_l} & \text{otherwise} \end{cases}$$

Contrasts

You can use the CONTRAST statement to perform custom hypothesis tests. If the hypothesis is testable in the univariate case, the Wald $F$ statistic for $H_0 : L \beta = 0$ is computed as

$$F_{\text{Wald}} = \frac{(L_{\text{Full}} \hat{\beta})' (L_{\text{Full}} \hat{\beta} V L_{\text{Full}})^{-1} (L_{\text{Full}} \hat{\beta})}{\text{rank}(L)}$$

where $L$ is the contrast vector or matrix you specify, $\beta$ is the vector of regression parameters, $\hat{\beta} = (X'WX)^{-1}X'WY$, $\hat{V}$ is the estimated covariance matrix of $\hat{\beta}$, rank($L$) is the rank of $L$, and $L_{\text{Full}}$ is a matrix such that

- $L_{\text{Full}}$ has the same number of columns as $L$
- $L_{\text{Full}}$ has full row rank
- the rank of $L_{\text{Full}}$ equals the rank of the $L$ matrix
- all rows of $L_{\text{Full}}$ are estimable functions
- the Wald $F$ statistic computed using the $L_{\text{Full}}$ matrix is equivalent to the Wald $F$ statistic computed using the $L$ matrix with any row deleted that is a linear combination of previous rows
If $L$ is a full-rank matrix, and all rows of $L$ are estimable functions, then $L_{\text{Full}}$ is the same as $L$. It is possible that $L_{\text{Full}}$ matrix cannot be constructed for contrasts in a CONTRAST statement, in which case the contrasts are not testable.

## Output

### Displayed Output

The SURVEYREG procedure produces the following output.

### Data Summary

By default, PROC SURVEYREG displays the following information in the “Data Summary” table:

- Number of Observations, which is the total number of observations used in the analysis, excluding observations with missing values
- Sum of Weights, if you specify a WEIGHT statement
- Mean of the dependent variable in the MODEL statement, or Weighted Mean if you specify a WEIGHT statement
- Sum of the dependent variable in the MODEL statement, or Weighted Sum if you specify a WEIGHT statement

### Design Summary

When you specify a CLUSTER statement or a STRATA statement, the procedure displays a “Design Summary” table, which provides the following sample design information:

- Number of Strata, if you specify a STRATA statement
- Number of Strata Collapsed, if the procedure collapses strata
- Number of Clusters, if you specify a CLUSTER statement
- Overall Sampling Rate used to calculate the design effect, if you specify the DEFF option in the MODEL statement

### Fit Statistics

By default, PROC SURVEYREG displays the following regression statistics in the “Fit Statistics” table:

- R-square for the regression
- Root MSE, which is the square root of the mean square error
- Denominator DF, which is the denominator degrees of freedom for the $F$ tests and also the degrees of freedom for the $t$ tests produced by the procedure
Stratum Information

When you specify the LIST option in the STRATA statement, PROC SURVEYREG displays a “Stratum Information” table, which provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variable(s), which lists the levels of STRATA variables for the stratum
- Population Total, if you specify the TOTAL= option
- Sampling Rate, if you specify the TOTAL= option or the RATE= option. If you specify the TOTAL= option, the sampling rate is based on the number of nonmissing observations in the stratum.
- N Obs, which is the number of observations
- number of Clusters, if you specify a CLUSTER statement
- Collapsed, which has the value ‘Yes’ if the stratum is collapsed with another stratum before analysis

If PROC SURVEYREG collapses strata, the “Stratum Information” table also displays stratum information for the new, collapsed stratum. The new stratum has a Stratum Index of 0 and is labeled ‘Pooled’.

Class Level Information

If you use a CLASS statement to name classification variables, PROC SURVEYREG displays a “Class Level Information” table. This table contains the following information for each classification variable:

- Class Variable, which lists each CLASS variable name
- Levels, which is the number of values or levels of the classification variable
- Values, which lists the values of the classification variable. The values are separated by a white space character; therefore, to avoid confusion, you should not include a white space character within a classification variable value.

X’X Matrix

If you specify the XPX option in the MODEL statement, PROC SURVEYREG displays the X’X matrix, or the X’WX matrix when there is a WEIGHT variable. This option also displays the crossproducts vector X’y or X’Wy, where y is the response vector (dependent variable).

Inverse Matrix of X’X

If you specify the INV option in the MODEL statement, PROC SURVEYREG displays the inverse or the generalized inverse of the X’X matrix. When there is a WEIGHT variable, the procedure displays the inverse or the generalized inverse of the X’WX matrix.
ANOVA for Dependent Variable

If you specify the ANOVA option in the model statement, PROC SURVEYREG displays an analysis of variance table for the dependent variable. This table is identical to the ANOVA table displayed by the GLM procedure.

Tests of Model Effects

By default, PROC SURVEYREG displays a “Tests of Model Effects” table, which provides Wald’s $F$ test for each effect in the model. The table contains the following information for each effect:

- **Effect**, which is the effect name
- **Num DF**, which is the numerator degrees of freedom for Wald’s $F$ test
- **F Value**, which is Wald’s $F$ statistic
- **Pr > F**, which is the significance probability corresponding to the $F$ Value

A footnote displays the denominator degrees of freedom, which is the same for all effects.

Estimated Regression Coefficients

PROC SURVEYREG displays the “Estimated Regression Coefficients” table by default when there is no CLASS statement. Also, the procedure displays this table when you specify a CLASS statement and also specify the SOLUTIONS option in the MODEL statement. This table contains the following information for each regression parameter:

- **Parameter**, which identifies the effect or regressor variable
- **Estimate**, which is the estimate of the regression coefficient
- **Standard Error**, which is the standard error of the estimate
- **t Value**, which is the $t$ statistic for testing $H_0$: Parameter $= 0$
- **Pr > |t|**, which is the two-sided significance probability corresponding to the $t$ Value

Covariance of Estimated Regression Coefficients

When you specify the COVB option in the MODEL statement, PROC SURVEYREG displays the “Covariance of Estimated Regression Coefficients” matrix.

Coefficients of Contrast

When you specify the E option in a CONTRAST statement, PROC SURVEYREG displays a “Coefficients of Contrast” table for the contrast. You can use this table to check the coefficients you specified in the CONTRAST statement. Also, this table gives a note for a nonestimable contrast.
Analysis of Contrasts

If you specify a CONTRAST statement, PROC SURVEYREG produces an “Analysis of Contrasts” table, which displays Wald’s $F$ test for the contrast. If you use more than one CONTRAST statement, the procedure displays all results in the same table. The “Analysis of Contrasts” table contains the following information for each contrast:

- Contrast, which is the label of the contrast
- Num DF, which is the numerator degrees of freedom for Wald’s $F$ test
- $F$ Value, which is Wald’s $F$ statistic for testing $H_0$: Contrast = 0
- Pr > $F$, which is the significance probability corresponding to the $F$ Value

Coefficients of Estimate

When you specify the E option in an ESTIMATE statement, PROC SURVEYREG displays a “Coefficients of Estimate” table for the linear function of the regression parameters in the ESTIMATE statement. You can use this table to check the coefficients you specified in the ESTIMATE statement. Also, this table gives a note for a nonestimable function.

Analysis of Estimable Functions

If you specify an ESTIMATE statement, PROC SURVEYREG checks the function for estimability. If the function is estimable, PROC SURVEYREG produces an “Analysis of Estimable Functions” table, which displays the estimate and the corresponding $t$ test. If you use more than one ESTIMATE statement, the procedure displays all results in the same table. The table contains the following information for each estimable function:

- Parameter, which is the label of the function
- Estimate, which is the estimate of the estimable linear function
- Standard Error, which is the standard error of the estimate
- $t$ Value, which is the $t$ statistic for testing $H_0$: Estimable Function = 0
- Pr > $|t|$, which is the two-sided significance probability corresponding to the $t$ Value

Output Data Sets

Output data sets from PROC SURVEYREG are produced using ODS (Output Delivery System). ODS encompasses more than just the production of output data sets. For example, you can use ODS to manipulate the format of your output, the headers and titles of the tables, the order of the columns in a table. For a more detailed description on using ODS, see Chapter 14, “Using the Output Delivery System.”
**ODS Table Names**

PROC SURVEYREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named `MyStrata`, which contains the “StrataInfo” table, an output data set named `MyParmEst`, which contains the “ParameterEstimates” table, and an output data set named `Cov`, which contains the “CovB” table for the ice cream study discussed in the section “Stratified Sampling” on page 4368:

```latex
title1 'Ice Cream Spending Analysis';
title2 'Stratified Simple Random Sample Design';
proc surveyreg data=IceCream total=StudentTotals;
   strata Grade /list;
   class Kids;
   model Spending = Income Kids / solution covb;
   weight Weight;
   ods output StrataInfo = MyStrata
      ParameterEstimates = MyParmEst
      CovB = Cov;
run;
```
Note that the option CovB is specified in the MODEL statement in order to produce the covariance matrix table.

Examples

Example 71.1. Simple Random Sampling

This example investigates the relationship between the labor force participation rate (LFPR) of women in 1968 and 1972 in large cities in the United States. A simple random sample of 19 cities is drawn from a total of 200 cities. For each selected city, the LFPRs are recorded and saved in a SAS data set named Labor. The LFPR in 1972 is contained in the variable LFPR1972, and the LFPR in 1968 is identified by the variable LFPR1968:

```sas
data Labor;
  input City $ 1-16 LFPR1972 LFPR1968;
  datalines;
New York .45 .42
Los Angeles .50 .50
Chicago .52 .52
Philadelphia .45 .45
Detroit .46 .43
San Francisco .55 .55
Boston .60 .45
Pittsburgh .49 .34
St. Louis .35 .45
Connecticut .55 .54
Washington D.C. .52 .42
Cincinnati .53 .51
Baltimore .57 .49
Newark .53 .54
Minn/St. Paul .59 .50
Buffalo .64 .58
Houston .50 .49
Patterson .57 .56
Dallas .64 .63
;
```

Assume that the LFPRs in 1968 and 1972 have a linear relationship, as shown in the following model:

\[ \text{LFPR1972} = \beta_0 + \beta_1 \times \text{LFPR1968} + \text{error} \]

You can use PROC SURVEYREG to obtain the estimated regression coefficients and estimated standard errors of the regression coefficients. The following statements perform the regression analysis:

```sas
title 'Study of Labor Force Participation Rates of Women';
proc surveyreg data=Labor total=200;
  model LFPR1972 = LFPR1968;
run;
```
Here, the TOTAL=200 option specifies the finite population total from which the simple random sample of 19 cities is drawn. You can specify the same information by using the sampling rate option RATE=0.095 (19/200=.095).

**Output 71.1.1. Summary of Regression Using Simple Random Sampling**

```

</tr>
</tbody>
</table>

NOTE: The denominator degrees of freedom for the t tests is 18.
Output 71.1.2 presents the significance tests for the model effects and estimated regression coefficients. The $F$ tests and $t$ tests for the effects in the model are also presented in these tables.

From the regression performed by PROC SURVEYREG, you obtain a positive estimated slope for the linear relationship between the LFPR in 1968 and the LFPR in 1972. The regression coefficients are all significant at the 5% level. Effects Intercept and LFPR1968 are significant in the model at the 5% level. In this example, the $F$ test for the overall model without intercept is the same as the effect LFPR1968.

Example 71.2. Simple Random Cluster Sampling

This example illustrates the use of regression analysis in a simple random cluster sample design. The data are from Särndal, Swenson, and Wretman (1992, p. 652).

A total of 284 Swedish municipalities are grouped into 50 clusters of neighboring municipalities. Five clusters with a total of 32 municipalities are randomly selected. The results from the regression analysis in which clusters are used in the sample design are compared to the results of a regression analysis that ignores the clusters. The linear relationship between the population in 1975 and in 1985 is investigated.

The 32 selected municipalities in the sample are saved in the data set Municipalities:

```plaintext
data Municipalities;
  input Municipality Cluster Population85 Population75;
datalines;
  205  37   5   5
  206  37  11  11
  207  37  13  13
  208  37   8   8
  209  37  17  19
    6   2  16  15
    7   2  70  62
    8   2  66  54
    9   2  12  12
   10   2  60  50
   94  17   7   7
   95  17  16  16
   96  17  13  11
   97  17  12  11
   98  17  70  67
   99  17  20  20
  100  17  31  28
  101  17  49  48
  276  50   6   7
  277  50   9  10
  278  50  24  26
  279  50  10   9
  280  50  67  64
  281  50  39  35
  282  50  29  27
  283  50  10   9
  284  50  27  31
```
The variable Municipality identifies the municipalities in the sample; the variable Cluster indicates the cluster to which a municipality belongs; and the variables Population85 and Population75 contain the municipality populations in 1985 and in 1975 (in thousands), respectively. A regression analysis is performed by PROC SURVEYREG with a CLUSTER statement:

```
title1 'Regression Analysis for Swedish Municipalities';
title2 'Cluster Simple Random Sampling';
proc surveyreg data=Municipalities total=50;
    cluster Cluster;
    model Population85=Population75;
run;
```

The TOTAL=50 option specifies the total number of clusters in the sampling frame.

**Output 71.2.1.** Regression Analysis for Simple Random Cluster Sampling

| Parameter     | Estimate  | Standard Error | t Value | Pr > |t| |
|---------------|-----------|----------------|---------|------|---|
| Intercept     | -0.0191292| 0.89204053     | -0.02   | 0.9839 |
| Population75  | 1.0546253 | 0.05167565     | 20.41   | <.0001 |

NOTE: The denominator degrees of freedom for the t tests is 4.
Output 71.2.1 displays the data summary, design summary, fit statistics, and regression coefficient estimates. Since the sample design includes clusters, the procedure displays the total number of clusters in the sample in the “Design Summary” table. In the “Estimated Regression Coefficients” table, the estimated slope for the linear relationship is 1.05, which is significant at the 5% level; but the intercept is not significant. This suggests that a regression line crossing the original can be established between populations in 1975 and in 1985.

The CLUSTER statement is necessary in PROC SURVEYREG in order to incorporate the sample design. If you do not specify a CLUSTER statement in the regression analysis, the standard deviation of the regression coefficients will be incorrectly estimated:

```
title1 'Regression Analysis for Swedish Municipalities';
title2 'Simple Random Sampling';
proc surveyreg data=Municipalities total=284;
   model Population85=Population75;
run;
```

The analysis ignores the clusters in the sample, assuming that the sample design is a simple random sampling. Therefore, the TOTAL= option specifies the total number of municipalities, which is 284.

**Output 71.2.2.** Regression Analysis for Simple Random Sampling

<table>
<thead>
<tr>
<th>Regression Analysis for Swedish Municipalities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simple Random Sampling</td>

**Estimated Regression Coefficients**

| Parameter  | Estimate | Standard Error | t Value | Pr > |t|  |
|------------|----------|----------------|---------|-------|-----|
| Intercept  | -0.0191292 | 0.67417606 | -0.03 | 0.9775 |
| Population75 | 1.0546253 | 0.03668414 | 28.75 | <.0001 |

**NOTE:** The denominator degrees of freedom for the t tests is 31.
Output 71.2.2 displays the regression results ignoring the clusters. Compared to the results in Output 71.2.1 on page 4398, the regression coefficient estimates are the same. However, without using clusters, the regression coefficients have a smaller variance estimate in Output 71.2.2. Using clusters in the analysis, the estimated regression coefficient for effect Population75 is 1.05, with the estimated standard error 0.05, as displayed in Output 71.2.1; without using the clusters, the estimate is 1.05, but with the estimated standard error 0.04, as displayed in Output 71.2.2. To estimated the variance of the regression coefficients correctly, you should include the clustering information in the regression analysis.

Example 71.3. Regression Estimator for Simple Random Sample

Using auxiliary information, you can construct the regression estimators to provide more accurate estimates of the population characteristics that are of interest. With ESTIMATE statements in PROC SURVEYREG, you can specify a regression estimator as a linear function of the regression parameters to estimate the population total. This example illustrates this application, using the data in the previous example.

In this sample, a linear model between the Swedish populations in 1975 and in 1985 is established:

\[
\text{Population85} = \alpha + \beta \times \text{Population75} + \text{error}
\]

Assuming that the total population in 1975 is known to be 8200 (in thousands), you can use the ESTIMATE statement to predict the 1985 total population using the following statements:

```plaintext
title1 'Regression Analysis for Swedish Municipalities';
title2 'Estimate Total Population';
proc surveyreg data=Municipalities total=50;
  cluster Cluster;
  model Population85=Population75;
  estimate '1985 population' Intercept 284 Population75 8200;
run;
```

Since each observation in the sample is a municipality, and there is a total of 284 municipalities in Sweden, the coefficient for Intercept (\(\alpha\)) in the ESTIMATE statement is 284, and the coefficient for Population75 (\(\beta\)) is the total population in 1975 (8.2 million).
Example 71.4. Stratified Sampling

Output 71.3.1. Use the Regression Estimator to Estimate the Population Total

| Parameter     | Estimate | Standard Error | t Value | Pr > |t| |
|---------------|----------|----------------|---------|------|---|
| 1985 population | 8642.49485 | 258.558613 | 33.43 | <.0001 |

NOTE: The denominator degrees of freedom for the t tests is 4.

Output 71.3.1 displays the regression results and the estimation of the total population. Using the linear model, you can predict the total population in 1985 to be 8.64 million, with a standard error of 0.26 million.

Example 71.4. Stratified Sampling

This example illustrates using the SURVEYREG procedure to perform a regression in a stratified sample design. Consider a population of 235 farms producing corn in Nebraska and Iowa. You are interested in the relationship between corn yield (CornYield) and the total farm size (FarmArea).

Each state is divided into several regions, and each region is used as a stratum. Within each stratum, a simple random sample with replacement is drawn. A total of 19 farms is selected using a stratified simple random sample. The sample size and population size within each stratum are displayed in Table 71.3.

Table 71.3. Number of Farms in Each Stratum

<table>
<thead>
<tr>
<th>Stratum</th>
<th>State</th>
<th>Region</th>
<th>Number of Farms</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Iowa</td>
<td>1</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td>2</td>
<td>50</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>3</td>
<td>15</td>
</tr>
<tr>
<td>4</td>
<td>Nebraska</td>
<td>1</td>
<td>30</td>
</tr>
<tr>
<td>5</td>
<td></td>
<td>2</td>
<td>40</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td></td>
<td>235</td>
</tr>
</tbody>
</table>

Three models for the data are considered:

- Model I — Common intercept and slope:
  \[ \text{Corn Yield} = \alpha + \beta \times \text{Farm Area} \]

- Model II — Common intercept, different slope:
  \[ \text{Corn Yield} = \begin{cases} 
  \alpha + \beta_{\text{Iowa}} \times \text{Farm Area} & \text{if the farm is in Iowa} \\
  \alpha + \beta_{\text{Nebraska}} \times \text{Farm Area} & \text{if the farm is in Nebraska} 
\end{cases} \]
Model III — Different intercept and different slope:

\[ \text{Corn Yield} = \begin{cases} \alpha_{\text{Iowa}} + \beta_{\text{Iowa}} \times \text{Farm Area} & \text{if the farm is in Iowa} \\ \alpha_{\text{Nebraska}} + \beta_{\text{Nebraska}} \times \text{Farm Area} & \text{if the farm is in Nebraska} \end{cases} \]

Data from the stratified sample are saved in the SAS data set Farms. In the data set Farms, the variable Weight represents the sampling weight. In this example, the sampling weights are reciprocal of selection probabilities:

```sas
data Farms;
  input State $ Region FarmArea CornYield Weight;
  datalines;
  Iowa 1 100 54 33.333
  Iowa 1 83 25 33.333
  Iowa 1 25 10 33.333
  Iowa 2 120 83 10.000
  Iowa 2 50 35 10.000
  Iowa 2 110 65 10.000
  Iowa 2 60 35 10.000
  Iowa 2 45 20 10.000
  Iowa 3 23 5 5.000
  Iowa 3 10 8 5.000
  Iowa 3 350 125 5.000
  Nebraska 1 130 20 5.000
  Nebraska 1 245 25 5.000
  Nebraska 1 150 33 5.000
  Nebraska 1 263 50 5.000
  Nebraska 1 320 47 5.000
  Nebraska 1 204 25 5.000
  Nebraska 2 80 11 20.000
  Nebraska 2 48 8 20.000
;```

The information on population size in each stratum is saved in the SAS data set StratumTotals:

```sas
data StratumTotals;
  input State $ Region _TOTAL_;
  datalines;
  Iowa 1 100
  Iowa 2 50
  Iowa 3 15
  Nebraska 1 30
  Nebraska 2 40
;```

Using the sample data from the data set Farms and the control information data from the data set StratumTotals, you can fit Model I using PROC SURVEYREG with the following statements:
Example 71.4. Stratified Sampling

```sas
title1 'Analysis of Farm Area and Corn Yield';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
  strata State Region / list;
  model CornYield = FarmArea;
  weight Weight;
run;
```

**Output 71.4.1.** Data Summary and Stratum Information Fitting Model I

NOTE: The denominator degrees of freedom for the F tests is 14.

Estimated Regression Coefficients

| Parameter    | Estimate   | Standard Error | t Value | Pr > |t| |
|--------------|------------|----------------|---------|------|---|
| Intercept    | 11.816278  | 5.31981027     | 2.22    | 0.0433 |
| FarmArea     | 0.2126576  | 0.04560949     | 4.66    | 0.0004 |

NOTE: The denominator degrees of freedom for the t tests is 14.

Output 71.4.2 displays tests of model effects and the estimated regression coefficients.

Alternatively, you can assume that the linear relationship between corn yield (CornYield) and farm area (FarmArea) is different among the states (Model II). In order to analyze the data using this model, you create auxiliary variables FarmAreaNE and FarmAreaIA to represent farm area in different states:

\[
\text{FarmAreaNE} = \begin{cases} 
0 & \text{if the farm is in Iowa} \\
\text{FarmArea} & \text{if the farm is in Nebraska} 
\end{cases}
\]

\[
\text{FarmAreaIA} = \begin{cases} 
\text{FarmArea} & \text{if the farm is in Iowa} \\
0 & \text{if the farm is in Nebraska} 
\end{cases}
\]

The following statements create these variables in a new data set called FarmsByState and use PROC SURVEYREG to fit Model II:

```r
title1 'Analysis of Farm Area and Corn Yield';
title2 'Model II: Same Intercept, Different Slopes';
data FarmsByState; set Farms;
  if State='Iowa' then do;
    FarmAreaIA=FarmArea; FarmAreaNE=0; end;
  else do;
    FarmAreaIA=0; FarmAreaNE=FarmArea; end;
run;
```
The following statements perform the regression using the new data set FarmsByState. The analysis uses the auxiliary variables FarmAreaIA and FarmAreaNE as the regressors:

```sas
proc SURVEYREG data=FarmsByState total=StratumTotals;
   strata State Region;
   model CornYield = FarmAreaIA FarmAreaNE;
   weight Weight;
run;
```

**Output 71.4.3.** Regression Results from Fitting Model II

| Parameter   | Estimate  | Standard Error | t Value | Pr > |t|     |
|-------------|-----------|----------------|---------|-------|-------|
| Intercept   | 4.04234816 | 3.80934848     | 1.06    | 0.3066|
| FarmAreaIA  | 0.41696069 | 0.05971129     | 6.98    | <.0001|
| FarmAreaNE  | 0.12851012 | 0.02495495     | 5.15    | 0.0001|

NOTE: The denominator degrees of freedom for the t tests is 14.

Output 71.4.3 displays the data summary, design information, fit statistics, and parameter estimates. The estimated slope parameters for each state are quite different from the estimated slope in Model I. The results from the regression show that Model II fits these data better than Model I.

For Model III, different intercepts are used for the linear relationship in two states. The following statements illustrate the use of the NOINT option in the MODEL statement associated with the CLASS statement to fit Model III:
The model statement includes the classification effect State as a regressor. Therefore, the parameter estimates for effect State will present the intercepts in two states.

Output 71.4.4. Regression Results for Fitting Model III
Output 71.4.4 displays the regression results for fitting Model III, including the data summary, parameter estimates, and covariance matrix of the regression coefficients. The estimated covariance matrix shows a lack of correlation between the regression coefficients from different states. This suggests that Model III might be the best choice for building a model for farm area and corn yield in these two states.

However, some statistics remain the same under different regression models, for example, Weighted Mean of CornYield. These estimators do not rely on the particular model you use.

**Example 71.5. Regression Estimator for Stratified Sample**

This example uses the corn yield data from the previous example to illustrate how to construct a regression estimator for a stratified sample design.

Similar to Example 71.3 on page 4400, by incorporating auxiliary information into a regression estimator, the procedure can produce more accurate estimates of the population characteristics that are of interest. In this example, the sample design is a stratified sample design. The auxiliary information is the total farm areas in regions of each state, as displayed in Table 71.4. You want to estimate the total corn yield using this information under the three linear models given in Example 71.4.

**Table 71.4. Information for Each Stratum**

<table>
<thead>
<tr>
<th>Stratum</th>
<th>State</th>
<th>Region</th>
<th>Number of Farms in Population</th>
<th>Number of Farms in Sample</th>
<th>Total Farm Area</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Iowa</td>
<td>1</td>
<td>100</td>
<td>3</td>
<td>13,200</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td>2</td>
<td>50</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>3</td>
<td>15</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Nebraska</td>
<td>1</td>
<td>30</td>
<td>6</td>
<td>8,750</td>
</tr>
<tr>
<td>5</td>
<td></td>
<td>2</td>
<td>40</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td></td>
<td>235</td>
<td>19</td>
<td>21,950</td>
</tr>
</tbody>
</table>

The regression estimator to estimate the total corn yield under Model I can be obtained by using PROC SURVEYREG with an ESTIMATE statement:

```plaintext
title1 'Estimate Corn Yield from Farm Size';
title2 'Model I: Same Intercept and Slope';
proc surveyreg data=Farms total=StratumTotals;
  strata State Region / list;
  class State Region;
  model CornYield = FarmArea State*Region /solution;
  weight Weight;
  estimate 'Estimate of CornYield under Model I'
    INTERCEPT 235 FarmArea 21950
    State*Region 100 50 15 30 40 /e;
run;
```

To apply the constraint in each stratum that the weighted total number of farms equals to the total number of farms in the stratum, you can include the strata as an effect in the MODEL statement, effect State*Region. Thus, the CLASS statement must list the STRATA variables, State and Region, as classification variables. The following
ESTIMATE statement specifies the regression estimator, which is a linear function of the regression parameters:

```plaintext
estimate 'Estimate of CornYield under Model I'
   INTERCEPT 235 FarmArea 21950
   State*Region 100 50 15 30 40 /e;
```

This linear function contains the total for each explanatory variable in the model. Because the sampling units are farms in this example, the coefficient for Intercept in the ESTIMATE statement is the total number of farms (235); the coefficient for FarmArea is the total farm area listed in Table 71.4 (21950); and the coefficients for effect State*Region are the total number of farms in each strata (as displayed in Table 71.4).

**Output 71.5.1.** Regression Estimator for the Total of CornYield under Model I

```
Estimate Corn Yield from Farm Size
Model I: Same Intercept and Slope

The SURVEYREG Procedure

Regression Analysis for Dependent Variable CornYield

Analysis of Estimable Functions

| Parameter                                  | Estimate  | Standard Error | t Value | Pr > |t| |
|-------------------------------------------|-----------|----------------|---------|------|---|
| Estimate of CornYield under Model I       | 7463.52329| 926.841541     | 8.05    | <.0001

NOTE: The denominator degrees of freedom for the t tests is 14.
```

Output 71.5.1 displays the results of the ESTIMATE statement. The regression estimator for the total of CornYield in Iowa and Nebraska is 7464 under Model I, with a standard error of 927.

Under Model II, a regression estimator for totals can be obtained using the following statements:

```plaintext
title1 'Estimate Corn Yield from Farm Size';
title2 'Model II: Same Intercept, Different Slopes';
proc surveyreg data=FarmsByState total=StratumTotals;
   strata State Region;
   class State Region;
   model CornYield = FarmAreaIA FarmAreaNE
       state*region /solution;
   weight Weight;
   estimate 'Total of CornYield under Model II'
       INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
       State*Region 100 50 15 30 40 /e;
run;
```
In this model, you also need to include strata as a fixed effect in the MODEL statement. Other regressors are the auxiliary variables FarmAreaIA and FarmAreaNE (defined in Example 71.4). In the following ESTIMATE statement, the coefficient for Intercept is still the total number of farms; and the coefficients for FarmAreaIA and FarmAreaNE are the total farm area in Iowa and Nebraska, respectively, as displayed in Table 71.4. The total number of farms in each strata are the coefficients for the strata effect:

```
estimate 'Total of CornYield under Model II'
   INTERCEPT 235 FarmAreaIA 13200 FarmAreaNE 8750
   State*Region 100 50 15 30 40 /e;
```

Output 71.5.2 displays that the results of the regression estimator for the total of corn yield in two states under Model II is 7580 with a standard error of 859. The regression estimator under Model II has a slightly smaller standard error than under Model I.

Finally, you can apply Model III to the data and estimate the total corn yield. Under Model III, you can also obtain the regression estimators for the total corn yield for each state. Three ESTIMATE statements are used in the following statements to create the three regression estimators:

```
title1 'Estimate Corn Yield from Farm Size';
title2 'Model III: Different Intercepts and Slopes';
proc SURVEYREG data=FarmsByState total=StratumTotals;
   strata State Region;
   class State Region;
   model CornYield = state FarmAreaIA FarmAreaNE State*Region /noint solution;
   weight Weight;
   estimate 'Total CornYield in Iowa under Model III'
      State 165 0 FarmAreaIA 13200 FarmAreaNE 0
      State*Region 100 50 15 0 0 /e;
   estimate 'Total CornYield in Nebraska under Model III'
```

Output 71.5.2
The fixed effect \texttt{State} is added to the \texttt{MODEL} statement to obtain different intercepts in different states, using the NOINT option. Among the \texttt{ESTIMATE} statements, the coefficients for explanatory variables are different depending on which regression estimator is estimated. For example, in the \texttt{ESTIMATE} statement

\begin{verbatim}
estimate 'Total CornYield in Iowa under Model III'
State 165 0 FarmAreaIA 13200 FarmAreaNE 0
State*Region 100 50 15 0 0 /e;
\end{verbatim}

the coefficients for the effect \texttt{State} are 165 and 0, respectively. This indicates that the total number of farms in Iowa is 165 and the total number of farms in Nebraska is 0, because the estimation is the total corn yield in Iowa only. Similarly, the total numbers of farms in three regions in Iowa are used for the coefficients of the strata effect \texttt{State*Region}, as displayed in Table 71.4.

\textbf{Output 71.5.3.}  Regression Estimator for the Total of CornYield under Model III

\begin{table}[h]
\centering
\begin{tabular}{lcc}
\hline
\textbf{Parameter} & \textbf{Estimate} & \textbf{Error} \\
\hline
Total CornYield in Iowa under Model III & 6246.10697 & 851.272372 \\
Total CornYield in Nebraska under Model III & 1334.37961 & 116.302948 \\
Total CornYield in both states under Model III & 7580.48657 & 859.180439 \\
\hline
\end{tabular}
\caption{Estimate Corn Yield from Farm Size}
\end{table}

\textbf{Output 71.5.3} displays the results from the three regression estimators using Model III. Since the estimations are independent in each state, the total corn yield from both states is equal to the sum of the estimated total of corn yield in Iowa and Nebraska,
6246 + 1334 = 7580. This regression estimator is the same as the one under Model II. The variance of regression estimator of the total corn yield in both states is the sum of variances of regression estimators for total corn yield in each state. Therefore, it is not necessary to use Model III to obtain the regression estimator for the total corn yield unless you need to estimate the total corn yield for each individual state.

Example 71.6. Stratum Collapse

In a stratified sample, it is possible that some strata will have only one sampling unit. When this happens, PROC SURVEYREG collapses the strata that contain a single sampling unit into a pooled stratum. For more detailed information on stratum collapse, see the section “Stratum Collapse” on page 4388.

Suppose that you have the following data:

```
    data Sample;
      input Stratum X Y W;
    datalines;
    10 0 0 5
    10 1 1 5
    11 1 1 10
    11 1 2 10
    12 3 3 16
    33 4 4 45
    14 6 7 50
    12 3 4 16
    ;
```

The variable Stratum is again the stratification variable, the variable X is the independent variable, and the variable Y is the dependent variable. You want to regress Y on X. In the data set Sample, both Stratum=33 and Stratum=14 contain one observation. By default, PROC SURVEYREG collapses these strata into one pooled stratum in the regression analysis.

To input the finite population correction information, you create the SAS data set StratumTotals:

```
    data StratumTotals;
      input Stratum _TOTAL_;
    datalines;
    10 10
    11 20
    12 32
    33 40
    33 45
    14 50
    15 .
    66 70
    ;
```
The variable \texttt{Stratum} is the stratification variable, and the variable \texttt{TOTAL} contains the stratum totals. The data set \texttt{StratumTotals} contains more strata than the data set \texttt{Sample}. Also in the data set \texttt{StratumTotals}, more than one observation contains the stratum totals for \texttt{Stratum}=33:

\begin{verbatim}
  33 40
  33 45
\end{verbatim}

PROC \texttt{SURVEYREG} allows this type of input. The procedure simply ignores strata that are not present in the data set \texttt{Sample}; for the multiple entries of a stratum, the procedure uses the first observation. In this example, \texttt{Stratum}=33 has the stratum total \texttt{TOTAL}=40.

The following SAS statements perform the regression analysis:

\begin{verbatim}
title1 'Stratified Sample with Single Sampling Unit in Strata';
title2 'With Stratum Collapse';
proc SURVEYREG data=Sample total=StratumTotals;
   strata Stratum/list;
   model Y=X;
   weight W;
run;
\end{verbatim}

Output 71.6.1. Summary of Data and Regression

\begin{verbatim}
Stratified Sample with Single Sampling Unit in Strata
With Stratum Collapse

The SURVEYREG Procedure

Regression Analysis for Dependent Variable Y

\end{tabular}
\end{verbatim}

Output 71.6.1 displays that there are a total of five strata in the input data set, and two strata are collapsed into a pooled stratum. The denominator degrees of freedom
is 4, due to the collapse (see the section “Denominator Degrees of Freedom” on page 4386).

**Output 71.6.2.** Stratification Information

<table>
<thead>
<tr>

NOTE: Strata with only one observation are collapsed into the stratum with Stratum Index "0".

Output 71.6.2 displays the stratification information, including stratum collapse. Under the column Collapsed, the fourth stratum (Stratum=14) and the fifth (Stratum=33) are marked as ‘Yes’, which indicates that these two strata are collapsed into the pooled stratum (Stratum Index=0). The sampling rate for the pooled stratum is 2% (see the section “Sampling Rate of the Pooled Stratum from Collapse” on page 4389).
Output 71.6.3. Parameter Estimates and Effect Tests

Stratified Sample with Single Sampling Unit in Strata
With Stratum Collapse

The SURVEYSELECT procedure provides a variety of methods for selecting probability-based random samples. The procedure can select a simple random sample or can sample according to a complex multistage sample design that includes stratification, clustering, and unequal probabilities of selection. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population.

To select a sample with PROC SURVEYSELECT, you input a SAS data set that contains the sampling frame or list of units from which the sample is to be selected. You also specify the selection method, the desired sample size or sampling rate, and other selection parameters. The SURVEYSELECT procedure selects the sample, producing an output data set that contains the selected units, their selection probabilities, and sampling weights. When you are selecting a sample in multiple stages, you invoke the procedure separately for each stage of selection, inputting the frame and selection parameters for each current stage.

The SURVEYSELECT procedure provides methods for both equal probability sampling and probability proportional to size (PPS) sampling. In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. In PPS sampling, a unit’s selection probability is proportional to its size measure. For details on probability sampling methods, refer to Lohr (1999), Kish (1965, 1987), Kalton (1983), and Cochran (1977).

The SURVEYSELECT procedure provides the following equal probability sampling methods:

- simple random sampling
- unrestricted random sampling (with replacement)
- systematic random sampling
- sequential random sampling

This procedure also provides the following probability proportional to size (PPS) methods:

- PPS sampling without replacement
- PPS sampling with replacement
- PPS systematic sampling
- PPS algorithms for selecting two units per stratum
- sequential PPS sampling with minimum replacement
The procedure uses fast, efficient algorithms for these sample selection methods. Thus, it performs well even for large input data sets or sampling frames, which may occur in practice for large-scale sample surveys.

The SURVEYSELECT procedure can perform stratified sampling, selecting samples independently within the specified strata, or nonoverlapping subgroups of the survey population. Stratification controls the distribution of the sample size in the strata. It is widely used in practice toward meeting a variety of survey objectives. For example, with stratification you can ensure adequate sample sizes for subgroups of interest, including small subgroups, or you can use stratification toward improving the precision of the overall estimates. When you are using a systematic or sequential selection method, the SURVEYSELECT procedure also can sort by control variables within strata for the additional control of implicit stratification.

The SURVEYSELECT procedure provides replicated sampling, where the total sample is composed of a set of replicates, each selected in the same way. You can use replicated sampling to study variable nonsampling errors, such as variability in the results obtained by different interviewers. You can also use replication to compute standard errors for the combined sample estimates.

### Getting Started

In this example, an Internet service provider conducts a customer satisfaction survey. The survey population consists of the company’s current subscribers. The company plans to select a sample of customers from this population, interview the selected customers, and then make inferences about the entire survey population from the sample data.

The SAS data set `Customers` contains the sampling frame, which is the list of units in the survey population. The sample of customers will be selected from this sampling frame. The data set `Customers` is constructed from the company’s customer database. It contains one observation for each customer, with a total of 13,471 observations. Figure 72.1 displays the first 10 observations of the data set `Customers`.

<tr>
<td>10</td>
</tr>
</tbody>
</table>

**Figure 72.1.** Customers Data Set (First 10 Observations)
In the SAS data set Customers, the variable CustomerID uniquely identifies each customer. The variable State contains the state of the customer’s address. The company has customers in the following four states: Georgia (GA), Alabama (AL), Florida (FL), and South Carolina (SC). The variable Type equals ‘Old’ if the customer has subscribed to the service for more than one year; otherwise, the variable Type equals ‘New’. The variable Usage contains the customer’s average monthly service usage, in minutes.

The following sections illustrate the use of PROC SURVEYSELECT for probability sampling with three different designs for the customer satisfaction survey. All three designs are one stage, with customers as the sampling units. The first design is simple random sampling without stratification. In the second design, customers are stratified by state and type, and the sample is selected by simple random sampling within strata. In the third design, customers are sorted within strata by usage, and the sample is selected by systematic random sampling within strata.

**Simple Random Sampling**

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set using simple random sampling:

```plaintext
title 'Customer Satisfaction Survey';
proc surveyselect data=Customers
    method=srs n=100
    out=SampleSRS;
run;
```

The PROC SURVEYSELECT statement invokes the procedure. The DATA= option names the SAS data set Customers as the input data set from which to select the sample. The METHOD=SRS option specifies simple random sampling as the sample selection method. In simple random sampling, each unit has an equal probability of selection, and sampling is without replacement. Without-replacement sampling means that a unit cannot be selected more than once. The N=100 option specifies a sample size of 100 customers. The OUT= option stores the sample in the SAS data set SampleSRS.

Figure 72.2 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 100 customers is selected from the data set Customers by simple random sampling. With simple random sampling and no stratification in the sample design, the selection probability is the same for all units in the sample. In this sample, the selection probability for each customer equals 0.007423, which is the sample size (100) divided by the population size (13,471). The sampling weight equals 134.71 for each customer in the sample, where the weight is the inverse of the selection probability. If you specify the STATS option, PROC SURVEYSELECT includes the selection probabilities and sampling weights in the output data set. (This information is always included in the output data set for more complex designs.)
The random number seed is 39647. PROC SURVEYSELECT uses this number as the initial seed for random number generation. Since the SEED= option is not specified in the PROC SURVEYSELECT statement, the seed value is obtained using the time of day from the computer’s clock. You can specify SEED=39647 to reproduce this sample.

</tbody>
</table>

**Figure 72.2.** Sample Selection Summary

The sample of 100 customers is stored in the SAS data set SampleSRS. PROC SURVEYSELECT does not display this output data set. The following PROC PRINT statements display the first 20 observations of SampleSRS:

```sas
title1 'Customer Satisfaction Survey';
title2 'Sample of 100 Customers, Selected by SRS';
title3 '(First 20 Observations)';
proc print data=SampleSRS(obs=20);
run;
```

**Figure 72.3** displays the first 20 observations of the output data set SampleSRS, which contains the sample of customers. This data set includes all the variables from the DATA= input data set Customers. If you do not want to include all variables, you can use the ID statement to specify which variables to copy from the input data set to the output (sample) data set.
In this section, stratification is added to the sample design for the customer satisfaction survey. The sampling frame, or list of all customers, is stratified by \texttt{State} and \texttt{Type}. This divides the sampling frame into nonoverlapping subgroups formed from the values of the \texttt{State} and \texttt{Type} variables. Samples are then selected independently within the strata.

PROC \texttt{SURVEYSELECT} requires that the input data set be sorted by the \texttt{STRATA} variables. The following \texttt{PROC SORT} statements sort the \texttt{Customers} data set by the stratification variables \texttt{State} and \texttt{Type}:

```
proc sort data=Customers;
   by State Type;
run;
```

The following \texttt{PROC \texttt{FREQ}} statements display the crosstabulation of the \texttt{Customers} data set by \texttt{State} and \texttt{Type}:

```
proc freq data=Customers;
   tables State*Type;
run;
```

Figure 72.4. Stratification of Customers by State and Type

Figure 72.4 presents the table of State by Type for the 13,471 customers. There are four states and two levels of Type, forming a total of eight strata.

The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set according to the stratified sample design:

```sas
proc surveyselect data=Customers
    method=srs n=15
    seed=1953 out=SampleStrata;
    strata State Type;
    run;
```

The STRATA statement names the stratification variables State and Type. In the PROC SURVEYSELECT statement, the METHOD=SRS option specifies simple random sampling. The N=15 option specifies a sample size of 15 customers for each stratum. If you want to specify different sample sizes for different strata, you can use the N=SAS-data-set option to name a secondary data set that contains the stratum sample sizes. The SEED=1953 option specifies ’1953’ as the initial seed for random number generation.

Figure 72.5. Sample Selection Summary

Figure 72.5 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 120 customers are selected.

The following PROC PRINT statements display the first 30 observations of the output data set SampleStrata:

```plaintext
title1 'Customer Satisfaction Survey';
title2 'Sample Selected by Stratified Design';
title3 '(First 30 Observations)';
proc print data=SampleStrata(obs=30);
run;
```

Figure 72.6 displays the first 30 observations of the output data set SampleStrata, which contains the sample of 120 customers, 15 customers from each of the eight strata. The variable SelectionProb contains the selection probability for each customer in the sample. Since customers are selected with equal probability within strata in this design, the selection probability equals the stratum sample size (15) divided by the stratum population size. The selection probabilities differ from stratum to stratum since the population sizes differ. The selection probability for each customer in the first stratum (State='AL' and Type='New') is 0.012116, and the selection probability is 0.021246 for customers in the second stratum. The variable SamplingWeight contains the sampling weights, which are computed as inverse selection probabilities.

Figure 72.6. Customer Sample (First 30 Observations)

Stratified Sampling with Control Sorting

The next sample design for the customer satisfaction survey uses stratification by State. The sampling frame is also sorted by Type and Usage before sample selection, to provide additional control over the distribution of the sample. Customers are then selected by systematic random sampling within strata. Selection by systematic sampling, together with control sorting, spreads the sample uniformly over the range of type and usage values within each stratum or state. The following PROC SURVEYSELECT statements select a probability sample of customers from the Customers data set using this design:

```plaintext
title1 'Customer Satisfaction Survey';
title2 'Stratified Sampling with Control Sorting';
proc surveyselect data=Customers
   method=sys rate=.02
   seed=1234 out=SampleControl;
   strata State;
   control Type Usage;
run;
```
The STRATA statement names the stratification variable State. The CONTROL statement names the control variables Type and Usage. In the PROC SURVEYSELECT statement, the METHOD=SYS option requests systematic random sampling. The RATE=.02 option specifies a sampling rate of 2% for each stratum. The SEED=1234 option specifies the initial seed for random number generation.

Figure 72.7 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A sample of 271 customers is selected, using systematic random sampling within strata determined by State. The sampling frame Customers is sorted by control variables Type and Usage within strata. The type of sorting is serpentine, which is used by default since SORT=NEST is not specified. See the section “Sorting by CONTROL Variables” on page 4445 for a description of serpentine sorting. The sorted data set replaces the input data set. (To store the sorted input data in another data set, leaving the input data set unsorted, use the OUTSORT= option.) The output data set SampleControl contains the sample of customers.
Chapter 72. The SURVEYSELECT Procedure

Syntax

The following statements are available in PROC SURVEYSELECT:

```
PROC SURVEYSELECT options ;
   STRATA variables ;
   CONTROL variables ;
   SIZE variable ;
   ID variables ;
```

The PROC SURVEYSELECT statement invokes the procedure and optionally identifies input and output data sets. It also specifies the selection method, the sample size, and other sample design parameters. The SURVEYSELECT statement is required.

The SIZE statement identifies the variable that contains the size measures. It is required for any selection method that is probability proportional to size (PPS).

The remaining statements are optional. The STRATA statement identifies a variable or set of variables that stratify the input data set. When you specify a STRATA statement, PROC SURVEYSELECT selects samples independently from the strata formed by the STRATA variables. The CONTROL statement identifies variables for ordering units within strata. It can be used for systematic and sequential sampling methods. The ID statement identifies variables to copy from the input data set to the output data set of selected units.

The rest of this section gives detailed syntax information for the CONTROL, ID, SIZE, and STRATA statements in alphabetical order after the description of the PROC SURVEYSELECT statement.

**PROC SURVEYSELECT Statement**

```
PROC SURVEYSELECT options ;
```

The PROC SURVEYSELECT statement invokes the procedure and optionally identifies input and output data sets. If you do not name a DATA= input data set, the procedure selects the sample from the most recently created SAS data set. If you do not name an OUT= output data set to contain the sample of selected units, the procedure still creates an output data set and names it according to the DATA$n convention.

The PROC SURVEYSELECT statement also specifies the sample selection method, the sample size, and other sample design parameters. If you do not specify a selection method, PROC SURVEYSELECT uses simple random sampling (METHOD=SRS) if there is no SIZE statement. If you specify a SIZE statement but do not specify a selection method, PROC SURVEYSELECT uses probability proportional to size selection without replacement (METHOD=PPS). You must specify the sample size or sampling rate unless you request a method that selects two units from each stratum (METHOD=PPS_BREWER or METHOD=PPS_MURTHY).

You can use the SAMSIZEn option to specify the sample size, or you can use the SAMSIZE=SAS-data-set option to name a secondary input data set that contains
stratum sample sizes. You can also specify stratum sampling rates, minimum size measures, maximum size measures, and certainty size measures in the secondary input data set. See the descriptions of the SAMPSIZE=, SAMPRATE=, MINSIZE=, MAXSIZE=, and CERTSIZE= options. You can name only one secondary input data set in each invocation of the procedure.

The following table lists the options available with the PROC SURVEYSELECT statement. Descriptions follow in alphabetical order.

</table>

You can specify the following options in the PROC SURVEYSELECT statement:

**CERTSIZE**

requests automatic selection of those units with size measures greater than or equal to the stratum certainty size measure. You provide sampling unit size measures in the DATA= input data set variable named in the SIZE statement. And you provide the stratum certainty size measures in the secondary input data set variable _CERTSIZE_. Use the CERTSIZE option when you have already named the secondary input data set in another option, such as SAMPSIZE=SAS-data-set, SAMPRATE=SAS-data-set, MAXSIZE=SAS-data-set, or MINSIZE=SAS-data-set. You can name only one secondary input data set in each invocation of the procedure.
If any unit’s size measure is greater than or equal to the certainty size measure for its stratum, then PROC SURVEYSELECT selects this unit with certainty. Each certainty size measure must be a positive number. The CERTSIZE option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

If you want to specify a single certainty size measure in the PROC SURVEYSELECT statement, use the CERTSIZE= certain option.

CERTSIZE="certain"
specifies the certainty size measure. PROC SURVEYSELECT selects with certainty any unit with size measure greater than or equal to the value "certain", which must be a positive number. You provide size measures in the DATA= input data set variable named in the SIZE statement. This option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

If you request a stratified sample design with a STRATA statement and specify the CERTSIZE= option, PROC SURVEYSELECT uses the certainty size "certain" for all strata. If you do not want to use the same certainty size for all strata, use the CERTSIZE=SAS-data-set option to specify a certainty size for each stratum.

CERTSIZE=SAS-data-set
names a SAS data set that contains the certainty size measures for the strata. PROC SURVEYSELECT selects with certainty any unit with size measure greater than or equal to the certainty size measure for its stratum. You provide sampling unit size measures in the DATA= input data set variable named in the SIZE statement. And you provide the stratum certainty size measures in the CERTSIZE= input data set variable _CERTSIZE_. Each certainty size measure must be a positive number. This option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

The CERTSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the CERTSIZE= data set as in the DATA= data set. The CERTSIZE= data set must include a variable named _CERTSIZE_ that contains the certainty size measure for each stratum.

CERTSIZE=P= p
specifies the certainty proportion. PROC SURVEYSELECT selects with certainty any unit with size measure greater than or equal to the proportion p of the total size for all units in the stratum. The procedure repeats this process with the remaining units until no more certainty units are selected. You provide size measures in the DATA= input data set variable named in the SIZE statement. This option is available for METHOD=PPS and METHOD=PPS_SAMPFORD.

The certainty proportion must be a positive number. You can specify p as a number between 0 and 1. Or you can specify p in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

If you request a stratified sample design with a STRATA statement and specify the CERTSIZE=P= p option, PROC SURVEYSELECT uses the same certainty proportion p for all strata.
DATA=SAS-data-set
names the SAS data set from which PROC SURVEYSELECT selects the sample. If you omit the DATA= option, the procedure uses the most recently created SAS data set. In sampling terminology, the input data set is the *sampling frame*, or list of units from which the sample is selected.

**JTPROBS**
includes joint probabilities of selection in the OUT= output data set. This option is available for the following probability proportional to size selection methods: METHOD=PPS, METHOD=PPS_SAMPFORD, and METHOD=PPS_WR. By default, PROC SURVEYSELECT outputs joint selection probabilities for METHOD=PPS_BREWER and METHOD=PPS_MURTHY, which select two units per stratum.

For details on computation of joint selection probabilities for a particular sampling method, see the method description in the section “Sample Selection Methods” on page 4446. For more information on the contents of the output data set, see the section “Output Data Set” on page 4456.

**MAXSIZE**
requests that sampling unit size measures be adjusted according to the stratum maximum size measures in the secondary input data set. You provide sampling unit size measures in the DATA= input data set variable named in the SIZE statement. And you provide the stratum maximum size measures in the secondary input data set variable MAXSIZE_. Use the MAXSIZE option when you have already named the secondary input data set in another option, such as SAMPSIZE=SAS-data-set, SAMPRATE=SAS-data-set, MINSIZE=SAS-data-set, or CERTSIZE=SAS-data-set. You can name only one secondary input data set in each invocation of the procedure.

If any size measure exceeds the maximum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure downward to equal the maximum size measure. Each maximum size measure must be a positive number. The MAXSIZE option is available whenever you specify a SIZE statement for probability proportional to size selection and a STRATA statement for stratification.

If you want to specify a single maximum size value in the PROC SURVEYSELECT statement, use the MAXSIZE=max option.

**MAXSIZE=max**
specifies the maximum size measure allowed. If any size measure exceeds the value max, then PROC SURVEYSELECT adjusts this size measure to equal max, which must be a positive number. You provide size measures in the DATA= input data set variable named in the SIZE statement. This option is available whenever you specify a SIZE statement for selection with probability proportional to size.

If you request a stratified sample design with a STRATA statement and specify the MAXSIZE= option, PROC SURVEYSELECT uses the maximum size max for all strata. If you do not want to use the same maximum size for all strata, use the MAXSIZE=SAS-data-set option to specify a maximum size for each stratum.
names a SAS data set that contains the maximum size measures allowed for the strata. If any size measure exceeds the maximum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure downward to equal the maximum size measure. You provide sampling unit size measures in the DATA= input data set variable named in the SIZE statement. And you provide the stratum maximum size measures in the MAXSIZE= input data set variable _MAXSIZE_. Each maximum size measure must be a positive number. This option is available whenever you specify a SIZE statement for probability proportional to size selection and a STRATA statement for stratified selection.

The MAXSIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MAXSIZE= data set as in the DATA= data set. The MAXSIZE= data set must include a variable named _MAXSIZE_ that contains the maximum size measure for each stratum.

specifies the method for sample selection. If you do not specify the METHOD= option, by default, PROC SURVEYSELECT uses simple random sampling (METHOD=SRS) if there is no SIZE statement. If you specify a SIZE statement, the default selection method is probability proportional to size without replacement (METHOD=PPS). Valid values for name are as follows:

requests selection with probability proportional to size and without replacement. See the section “PPS Sampling without Replacement” on page 4449 for details. If you specify METHOD=PPS, you must name the size measure variable in the SIZE statement.

requests selection according to Brewer’s method. Brewer’s method selects two units from each stratum with probability proportional to size and without replacement. See the section “Brewer’s PPS Method” on page 4453 for details. If you specify METHOD=PPS_BREWER, you must name the size measure variable in the SIZE statement. You do not need to specify the sample size with the SAMPSIZE= option, since Brewer’s method selects two units from each stratum.

requests selection according to Murthy’s method. Murthy’s method selects two units from each stratum with probability proportional to size and without replacement. See the section “Murthy’s PPS Method” on page 4454 for details. If you specify METHOD=PPS_MURTHY, you must name the size measure variable in the SIZE statement. You do not need to specify the sample size with the SAMPSIZE= option, since Murthy’s method selects two units from each stratum.
PPS_SAMPFORD | SAMPFORD requests selection according to Sampford’s method. Sampford’s method selects units with probability proportional to size and without replacement. See the section “Sampford’s PPS Method” on page 4455 for details. If you specify METHOD=PPS_SAMPFORD, you must name the size measure variable in the SIZE statement.

PPS_SEQ | CHROMY requests sequential selection with probability proportional to size and with minimum replacement. This method is also known as Chromy’s method. See the section “PPS Sequential Sampling” on page 4452 for details. If you specify METHOD=PPS_SEQ, you must name the size measure variable in the SIZE statement.

PPS_SYS requests systematic selection with probability proportional to size. See the section “PPS Systematic Sampling” on page 4451 for details on this method. If you specify METHOD=PPS_SYS, you must name the size measure variable in the SIZE statement.

PPS_WR requests selection with probability proportional to size and with replacement. See the section “PPS Sampling with Replacement” on page 4451 for details on this method. If you specify METHOD=PPS_WR, you must name the size measure variable in the SIZE statement.

SEQ requests sequential selection according to Chromy’s method. If you specify METHOD=SEQ and do not specify a size measure variable with the SIZE statement, PROC SURVEYSELECT uses sequential zoned selection with equal probability and without replacement. See the section “Sequential Random Sampling” on page 4448 for details on this method. If you specify METHOD=SEQ and also name a size measure variable in the SIZE statement, PROC SURVEYSELECT uses METHOD=PPS_SEQ, which is sequential selection with probability proportional to size and with minimum replacement. See the section “PPS Sequential Sampling” on page 4452 for details.

SRS requests simple random sampling, which is selection with equal probability and without replacement. See the section “Simple Random Sampling” on page 4447 for details. This method is the default if you do not specify the METHOD= option and also do not specify a SIZE statement.

SYS requests systematic random sampling. If you specify METHOD=SYS and do not specify a size measure variable with the SIZE statement, PROC SURVEYSELECT uses systematic selection with equal probability. See the section “Systematic Random Sampling” on page 4448 for details on this method. If you specify METHOD=SYS and also name a size measure variable in the SIZE statement, PROC SURVEYSELECT uses METHOD=PPS_SYS, which is systematic selection with probability proportional to size. See the section “PPS Systematic Sampling” on page 4451 for details.
URS requests unrestricted random sampling, which is selection with equal probability and with replacement. See the section “Unrestricted Random Sampling” on page 4447 for details.

MINSIZE requests that sampling unit size measures be adjusted according to the stratum minimum size measures in the secondary input data set. You provide sampling unit size measures in the DATA= input data set variable named in the SIZE statement. And you provide the stratum minimum size measures in the secondary input data set variable _MINSIZE_. Use the MINSIZE option when you have already named the secondary input data set in another option, such as SAMP_SIZE=SAS-data-set, SAMPRATE=SAS-data-set, MAX_SIZE=SAS-data-set, or CERT_SIZE=SAS-data-set. You can name only one secondary input data set in each invocation of the procedure.

If any size measure is less than the minimum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure upward to equal the minimum size measure. Each minimum size measure must be a positive number. The MINSIZE option is available whenever you specify a SIZE statement for probability proportional to size selection and a STRATA statement for stratification.

If you want to specify a single minimum size value in the PROC SURVEYSELECT statement, use the MINSIZE=min option.

MIN_SIZE= specifies the minimum size measure allowed. If any size measure is less than the value min, then PROC SURVEYSELECT adjusts this size measure upward to equal min, which must be a positive number. You provide size measures in the DATA= input data set variable named in the SIZE statement. This option is available whenever you specify a SIZE statement for probability proportional to size.

If you request a stratified sample design with a STRATA statement and specify the MINSIZE= option, PROC SURVEYSELECT uses the minimum size min for all strata. If you do not want to use the same minimum size for all strata, use the MINSIZE=SAS-data-set option to specify a minimum size for each stratum.

MIN_SIZE=SAS-data-set names a SAS data set that contains the minimum size measures allowed for the strata. If any size measure is less than the minimum size measure for its stratum, then PROC SURVEYSELECT adjusts this size measure upward to equal the minimum size measure. You provide sampling unit size measures in the DATA= input data set variable named in the SIZE statement. And you provide the stratum minimum size measures in the MIN_SIZE= input data set variable _MIN_SIZE_. Each minimum size measure must be a positive number. This option is available whenever you specify a SIZE statement for probability proportional to size selection and a STRATA statement for stratified selection.

The MIN_SIZE= input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the MIN_SIZE= data set as in the DATA= data set. The MIN_SIZE= data set must include a variable named _MIN_SIZE_ that contains the minimum size measure for each stratum.
NMAX= n
specifies the maximum stratum sample size n for the SAMPRATE= option. When you specify the SAMPRATE= option, PROC SURVEYSELECT calculates the desired stratum sample size from the specified sampling rate and the total number of units in the stratum. If this sample size is greater than the value NMAX=n, then PROC SURVEYSELECT selects the maximum of n units.

The maximum sample size n must be a positive integer. The NMAX= option is available only with the SAMPRATE= option, which may be used with equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ).

NMIN= n
specifies the minimum stratum sample size n for the SAMPRATE= option. When you specify the SAMPRATE= option, PROC SURVEYSELECT calculates the desired stratum sample size from the specified sampling rate and the total number of units in the stratum. If this sample size is less than the value NMIN=n, then PROC SURVEYSELECT selects the minimum of n units.

The minimum sample size n must be a positive integer. The NMIN= option is available only with the SAMPRATE= option, which may be used with equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ).

NOPRINT
suppresses the display of all output. You can use the NOPRINT option when you want only to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

OUT= SAS-data-set
names the output data set that contains the sample. If you omit the OUT= option, the data set is named DATA n, where n is the smallest integer that makes the name unique.

The output data set contains the units selected for the sample, as well as design information and selection statistics, depending on the selection method and output options you specify. See the descriptions for the options JTPROBS, OUTHITS, OUTSEED, OUTSIZE, and STATS. For information on the contents of the output data set, see the section “Output Data Set” on page 4456.

By default, the output data set contains only those units selected for the sample. To include all observations from the input data set in the output data set, use the OUTALL option.

OUTALL
includes all observations from the input data set in the output data set. By default, the output data set includes only those observations selected for the sample. When you specify the OUTALL option, the output data set includes all observations from DATA= and also contains a variable to indicate each observation’s selection status. The variable Selected equals 1 for an observation selected for the sample, and equals
0 for an observation not selected. For information on the contents of the output data set, see the section “Output Data Set” on page 4456.

The OUTALL option is available only for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ).

OUTHITS
includes a separate observation in the output data set for each selection when the same unit is selected more than once. By default, the output data set contains only one observation for each selected unit, even if it is selected more than once, and the variable NumberHits contains the number of hits or selections for that unit. The OUTHITS option is available for selection methods that select with replacement or with minimum replacement (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ).

OUTSEED
includes the initial seed for each stratum in the output data set. The variable InitialSeed contains the stratum initial seed. See the section “Sample Selection Methods” on page 4446 for information on initial seeds and random number generation in PROC SURVEYSELECT.

To reproduce the same sample for any stratum in a subsequent execution of PROC SURVEYSELECT, you can specify the same stratum initial seed with the SEED=SAS-data-set option, along with the same sample selection parameters.

OUTSIZE
includes additional design and sampling frame parameters in the output data set. If you specify the OUTSIZE option, PROC SURVEYSELECT includes the sample size or sampling rate in the output data set. When you request the OUTSIZE option and also specify the SIZE statement, the procedure outputs the size measure total for the sampling frame. If you do not specify the SIZE statement, the procedure outputs the total number of sampling units in the frame. Also, PROC SURVEYSELECT includes the minimum size measure if you specify the MINSIZE= option, the maximum size measure if you specify the MAXSIZE= option, and the certainty size measure if you specify the CERTSIZE= option.

If you have a stratified design, the output data set includes the stratum-level values of these parameters. Otherwise, the output data set includes the overall population-level values.

For information on the contents of the output data set, see the section “Output Data Set” on page 4456.

OUTSORT=SAS-data-set
names an output data set that contains the sorted input data set. This option is available when you specify a CONTROL statement for systematic or sequential selection methods (METHOD=SYS, METHOD=PPS_SYS, METHOD=SEQ, and METHOD=PPS_SEQ). PROC SURVEYSELECT sorts the input data set by the CONTROL variables within strata before selecting the sample.

If you specify CONTROL variables but do not name an output data set with the OUTSORT= option, then the sorted data set replaces the input data set.
REP=\textit{nrep}

specifies the number of sample replicates. If you specify the REP= option, PROC SURVEYSELECT selects \textit{nrep} independent samples, each with the same specified sample size or sampling rate and the same sample design.

You can use replicated sampling to provide a simple method of variance estimation for any form of statistic, as well as to evaluate variable nonsampling errors such as interviewer differences. Refer to Lohr (1999), Kish (1965, 1987), and Kalton (1983) for information on replicated sampling.

\textbf{SAMPRATE=}\textit{r}

\textbf{RATE=}\textit{r}

specifies the sampling rate, which is the proportion of units selected for the sample. The sampling rate \textit{r} must be a positive number. You can specify \textit{r} as a number between 0 and 1. Or you can specify \textit{r} in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.

The SAMPRATE= option is available only for equal probability selection methods (\texttt{METHOD=SRS}, \texttt{METHOD=URS}, \texttt{METHOD=SYS}, and \texttt{METHOD=SEQ}). For systematic random sampling (\texttt{METHOD=SYS}), PROC SURVEYSELECT uses the inverse of the sampling rate \textit{r} as the interval. See the section “Systematic Random Sampling” on page 4448 for details. For other selection methods, PROC SURVEYSELECT converts the sampling rate \textit{r} to the sample size before selection, multiplying the rate by the number of units in the stratum or frame and rounding up to the nearest integer.

If you request a stratified sample design with a STRATA statement and specify the SAMPRATE=\textit{r} option, PROC SURVEYSELECT uses the sampling rate \textit{r} for each stratum. If you do not want to use the same sampling rate for each stratum, use the SAMPRATE=(\textit{values}) option or the SAMPRATE=SAS-data-set option to specify a sampling rate for each stratum.

\textbf{SAMPRATE=(values)}

\textbf{RATE=(values)}

specifies sampling rates for the strata. You can separate values with blanks or commas. The number of SAMPRATE= values must equal the number of strata in the input data set.

List the stratum sampling rate values in the order in which the strata appear in the input data set. If you use the SAMPRATE=(\textit{values}) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED options in the STRATA statement.

Each stratum sampling rate value must be a positive number. You can specify each value as a number between 0 and 1. Or you can specify a value in percentage form as a number between 1 and 100, and PROC SURVEYSELECT converts that number to a proportion. The procedure treats the value 1 as 100%, and not the percentage form 1%.
The `SAMP_RATE=` option is available only for equal probability selection meth- 
ods (`METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ`). For 
systematic random sampling (`METHOD=SYS`), PROC SURVEYSELECT uses the 
inverse of the stratum sampling rate as the interval for the stratum. See the section 
“Systematic Random Sampling” on page 4448 for details on systematic sampling. 
For other selection methods, PROC SURVEYSELECT converts the stratum sampling 
rate to a stratum sample size before selection, multiplying the rate by the number of 
units in the stratum and rounding up to the nearest integer.

`SAMP_RATE=SAS-data-set`

`RATE=SAS-data-set`

names a SAS data set that contains sampling rates for the strata. This input data 
set should contain all the STRATA variables, with the same type and length as in 
the `DATA=` data set. The STRATA groups should appear in the same order in the 
`SAMP_SIZE=` data set as in the `DATA=` data set. The `SAMP_RATE=` data set should 
have a variable `RATE` that contains the sampling rate for each stratum.

Each sampling rate value must be a positive number. You can specify each value 
as a number between 0 and 1. Or you can specify a value in percentage form as a 
number between 1 and 100, and PROC SURVEYSELECT converts that number to a 
proportion. The procedure treats the value 1 as 100%, and not the percentage form 
1%.

The `SAMP_RATE=` option is available only for equal probability selection meth- 
ods (`METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ`). For 
systematic random sampling (`METHOD=SYS`), PROC SURVEYSELECT uses the 
inverse of the stratum sampling rate as the interval for the stratum. See the section 
“Systematic Random Sampling” on page 4448 for details. For other selection 
methods, PROC SURVEYSELECT converts the stratum sampling rate to the stra- 
tum sample size before selection, multiplying the rate by the number of units in the 
stratum and rounding up to the nearest integer.

`SAMP_SIZE=n`

`N=n`

specifies the sample size, which is the number of units selected for the sample. The 
(sample size `n` must be a positive integer. For methods that select without replacement, 
the sample size `n` must not exceed the number of units in the input data set.

If you request a stratified sample design with a `STRATA` statement and specify the 
`SAMP_SIZE=n` option, PROC SURVEYSELECT selects `n` units from each stratum. 
For methods that select without replacement, the sample size `n` must not exceed the 
number of units in any stratum. If you do not want to select the same number of units 
from each stratum, use the `SAMP_SIZE=(values)` option or the `SAMP_SIZE=SAS-
data-set` option to specify different sample sizes for the strata.

For without-replacement selection methods, by default, PROC SURVEYSELECT 
does not allow you to specify a stratum sample size that is greater than the total 
number of units in the stratum. However, you can change this default by specifying 
the SELECTALL option. With the SELECTALL option, PROC SURVEYSELECT 
selects all stratum units whenever the stratum sample size exceeds the number of 
units in the stratum.
**PROC SURVEYSELECT Statement**  •  4441

- **SAMPSIZE=(values)**
  - Specifies sample sizes for the strata. You can separate values with blanks or commas. The number of SAMPSIZE= values must equal the number of strata in the input data set.
  - List the stratum sample size values in the order in which the strata appear in the input data set. If you use the SAMPSIZE=(values) option, the input data set must be sorted by the STRATA variables in ascending order. You cannot use the DESCENDING or NOTSORTED options in the STRATA statement.
  - Each stratum sample size value must be a positive integer. For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum. However, you can change this default by specifying the SELECTALL option. With the SELECTALL option, PROC SURVEYSELECT selects all stratum units whenever the stratum sample size exceeds the number of units in the stratum.

- **SAMPSIZE=SAS-data-set**
  - Names a SAS data set that contains the sample sizes for the strata. This input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPSIZE= data set as in the DATA= data set. The SAMPSIZE= data set should have a variable _NSIZE_ that contains the sample size for each stratum.
  - Each stratum sample size value must be a positive integer. For without-replacement selection methods, by default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum. However, you can change this default by specifying the SELECTALL option. With the SELECTALL option, PROC SURVEYSELECT selects all stratum units whenever the stratum sample size exceeds the number of units in the stratum.

- **SEED=number**
  - Specifies the initial seed for random number generation. The value of the SEED= option must be an integer. If you do not specify the SEED= option, or if the SEED= value is negative or zero, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. See the section “Sample Selection Methods” on page 4446 for more information.
  - Whether or not you specify the SEED= option, PROC SURVEYSELECT displays the value of the initial seed in the “Sample Selection Summary” table. If you need to reproduce the same sample in a subsequent execution of PROC SURVEYSELECT, you can specify this same seed value with the SEED= option, along with the same sample selection parameters, and PROC SURVEYSELECT will reproduce the sample.
  - If you request a stratified sample design with a STRATA statement, you can use the SEED=SAS-data-set option to specify an initial seed for each stratum. Otherwise, PROC SURVEYSELECT generates random numbers continuously across strata from
the random number stream initialized by the SEED= value, as described in the section “Sample Selection Methods” on page 4446.

To include the stratum initial seeds in the output data set, use the OUTSEED option.

**SEED=SAS-data-set**

names a SAS data set that contains initial seeds for the strata. This input data set should contain all the STRATA variables, with the same type and length as in the DATA= data set. The STRATA groups should appear in the same order in the SAMPSIZE= data set as in the DATA= data set. The SEED= data set should have a variable _SEED_ that contains the initial seed for each stratum.

Each stratum initial seed value should be an integer. If the initial seed value for the first stratum is not a positive integer, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. If the initial seed value for a subsequent stratum is not a positive integer, PROC SURVEYSELECT continues to use the random number stream already initialized by the seed for the previous stratum. See the section “Sample Selection Methods” on page 4446 for more information.

To include the stratum initial seeds in the output data set, specify the **OUTSEED** option.

If you specified initial seeds by strata with the **SEED=SAS-data-set** option, you can reproduce the same sample in a subsequent execution of PROC SURVEYSELECT by specifying these same stratum initial seeds, along with the same sample selection parameters. If you need to reproduce the same sample for only a subset of the strata, you can use the same initial seeds for those strata in the subset.

**SELECTALL**

requests that PROC SURVEYSELECT select all stratum units whenever the stratum sample size exceeds the total number of units in the stratum, for without-replacement selection methods. By default, PROC SURVEYSELECT does not allow you to specify a stratum sample size that is greater than the total number of units in the stratum, for methods that select without replacement.

The SELECTALL option is available for without-replacement selection methods, which include **METHOD=SRS**, **METHOD=SYS**, **METHOD=SEQ**, **METHOD=PPS**, and **METHOD=PPS-SAMPFORD**. The SELECTALL option is not available for with-replacement selection methods, with-minimum-replacement methods, or for those PPS methods that select two units per stratum.

**SORT=NEST | SERP**

specifies the type of sorting by CONTROL variables. The option **SORT=NEST** requests nested sorting, and **SORT=SERP** requests hierarchic serpentine sorting. The default is **SORT=SERP**. See the section “Sorting by CONTROL Variables” on page 4445 for descriptions of serpentine and nested sorting. Where there is only one CONTROL variable, the two types of sorting are equivalent.

This option is available when you specify a **CONTROL** statement for systematic or sequential selection methods (**METHOD=SYS**, **METHOD=PPS_SYS**, **METHOD=SEQ**, and **METHOD=PPS_SEQ**). When you specify a **CONTROL**
statement, PROC SURVEYSELECT sorts the input data set by the CONTROL variables within strata before selecting the sample.

With sorting by CONTROL variables, you can also use the OUTSORT= option to name an output data set that contains the sorted input data set. Otherwise, if you do not specify the OUTSORT= option, then the sorted data set replaces the input data set.

### STATS
includes selection probabilities and sampling weights in the OUT= output data set for equal probability selection methods when you do not specify a STRATA statement. This option is available for the following equal probability selection methods: METHOD=SRS, METHOD=URS, METHOD=SYS, and METHOD=SEQ. For PPS selection methods and stratified designs, the output data set contains selection probabilities and sampling weights by default. For more information on the contents of the output data set, see the section “Output Data Set” on page 4456.

---

**CONTROL Statement**

```
CONTROL variables;
```

The CONTROL statement names variables for sorting the input data set. The CONTROL variables can be character or numeric.

PROC SURVEYSELECT sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a STRATA statement, PROC SURVEYSELECT sorts by CONTROL variables within strata. Control sorting is available for systematic and sequential selection methods (METHOD=SYS, METHOD=PPS_SYS, METHOD=SEQ, and METHOD=PPS_SEQ).

By default, PROC SURVEYSELECT uses hierarchic serpentine sorting by the CONTROL variables. If you specify the SORT=NEST option, the procedure uses nested sorting. See the description for the SORT= option. For more information on serpentine and nested sorting, see the section “Sorting by CONTROL Variables” on page 4445.

You can use the OUTSORT= option to name an output data set that contains the sorted input data set. If you do not specify the OUTSORT= option when you use the CONTROL statement, then the sorted data set replaces the input data set.

---

**ID Statement**

```
ID variables;
```

The ID statement names variables from the DATA= input data set to be included in the OUT= data set of selected units. If there is no ID statement, PROC SURVEYSELECT includes all variables from the DATA= data set in the OUT= data set. The ID variables can be character or numeric.
SIZE Statement

```
SIZE variable ;
```

The SIZE statement names one and only one size measure variable, which contains the size measures to be used when sampling with probability proportional to size. The SIZE variable must be numeric. When the value of an observation’s SIZE variable is missing or nonpositive, that observation has no chance of being selected for the sample.

The SIZE statement is required for all PPS selection methods, which include `METHOD=PPS`, `METHOD=PPS_BREWER`, `METHOD=PPS_MURTHY`, `METHOD=PPS_SAMPFORD`, `METHOD=PPS_SEQ`, `METHOD=PPS_SYS`, and `METHOD=PPS_WR`. For details on how size measures are used, see the descriptions of PPS methods in the section “Sample Selection Methods” on page 4446.

Note that a unit’s size measure, specified in the SIZE statement and used for PPS selection, is not the same as the sample size. The sample size is the number of units selected for the sample, and you can specify this with the `SAMPLESIZE=` option.

STRATA Statement

```
STRATA variables ;
```

You can specify a STRATA statement with PROC SURVEYSELECT to partition the input data set into nonoverlapping groups defined by the STRATA variables. PROC SURVEYSELECT then selects independent samples from these strata, according to the selection method and design parameters specified in the PROC SURVEYSELECT statement. For information on the use of stratification in sample design, refer to Lohr (1999), Kalton (1983), Kish (1965, 1987), and Cochran (1977).

The `variables` are one or more variables in the input data set. The STRATA variables function much like BY variables, and PROC SURVEYSELECT expects the input data set to be sorted in order of the STRATA variables.

If you specify a CONTROL statement, or if you specify `METHOD=PPS`, the input data set must be sorted in ascending order of the STRATA variables. This means you cannot use the STRATA option NOTSORTED or DESCENDING when you specify a CONTROL statement or `METHOD=PPS`.

If your input data set is not sorted by the STRATA variables in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with the STRATA variables in a BY statement.
- Specify the option NOTSORTED or DESCENDING in the STRATA statement for the SURVEYSELECT procedure (when you do not specify a CONTROL statement or `METHOD=PPS`). The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the STRATA variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the STRATA variables using the DATASETS procedure.
For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

### Details

#### Missing Values

If an observation has a missing or nonpositive value for the `SIZE` variable, PROC `SURVEYSELECT` excludes that observation from the sample selection. The procedure writes a note to the log giving the number of observations omitted due to missing or nonpositive size measures.

PROC `SURVEYSELECT` treats missing `STRA TA` variable values like any other `STRA TA` variable value. The missing values form a separate stratum.

If a value of `_NSIZE_` is missing in the `SAMPLESIZE=` input data set, then PROC `SURVEYSELECT` writes an error message to the log and does not select a sample from that stratum. The procedure treats missing values of `_NRATE_`, `_MINSIZE_`, `_MAXSIZE_`, and `_CERTSIZE_` similarly.

### Sorting by CONTROL Variables

If you specify a `CONTROL` statement, PROC `SURVEYSELECT` sorts the input data set by the CONTROL variables before selecting the sample. If you also specify a `STRA TA` statement, the procedure sorts by CONTROL variables within strata. Sorting by CONTROL variables is available for systematic and sequential selection methods, which include `METHOD=SYS`, `METHOD=PPS_SYS`, `METHOD=SEQ`, and `METHOD=PPS_SEQ`. Sorting provides additional control over the distribution of the sample, giving some benefits of proportionate stratification.

By default, the sorted data set replaces the input data set. Or you can use the `OUTSORT=` option to name an output data set that contains the sorted input data set.

PROC `SURVEYSELECT` provides two types of sorting: nested sorting and hierarchic serpentine sorting. If you specify the `SORT=NEST` option, then the procedure sorts by the CONTROL variables according to nested sorting. If you do not specify the `SORT=NEST` option, the procedure uses serpentine sorting by default. These two types of sorting are equivalent when there is only one CONTROL variable.

If you request nested sorting, PROC `SURVEYSELECT` sorts observations in the same order as PROC `SORT` does for an ascending sort by the CONTROL variables. Refer to the chapter on the `SORT` procedure in the *SAS Procedures Guide*. PROC `SURVEYSELECT` sorts within strata if you also specify a `STRA TA` statement. The procedure first arranges the input observations in ascending order of the first CONTROL variable. Then within each level of the first control variable, the procedure arranges the observations in ascending order of the second CONTROL variable. This continues for all CONTROL variables specified.
In hierarchic serpentine sorting, PROC SURVEYSELECT sorts by the first CONTROL variable in ascending order. Then within the first level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in ascending order. Within the second level of the first CONTROL variable, the procedure sorts by the second CONTROL variable in descending order. Sorting by the second CONTROL variable continues to alternate between ascending and descending sorting throughout all levels of the first CONTROL variable. If there is a third CONTROL variable, the procedure sorts by that variable within levels formed from the first two CONTROL variables, again alternating between ascending and descending sorting. This continues for all CONTROL variables specified. This sorting algorithm minimizes the change from one observation to the next with respect to the CONTROL variable values, thus making nearby observations more similar. For more information on serpentine sorting, refer to Chromy (1979) and Williams and Chromy (1980).

Sample Selection Methods

PROC SURVEYSELECT provides a variety of methods for selecting probability-based random samples. With probability sampling, each unit in the survey population has a known, positive probability of selection. This property of probability sampling avoids selection bias and enables you to use statistical theory to make valid inferences from the sample to the survey population. Refer to Lohr (1999), Kish (1965, 1987), Kalton (1983), and Cochran (1977) for more information on probability sampling.

In equal probability sampling, each unit in the sampling frame, or in a stratum, has the same probability of being selected for the sample. PROC SURVEYSELECT provides the following methods that select units with equal probability: simple random sampling, unrestricted random sampling, systematic random sampling, and sequential random sampling. In simple random sampling, units are selected without replacement, which means that a unit cannot be selected more than once. Both systematic and sequential equal probability sampling are also without replacement. In unrestricted random sampling, units are selected with replacement, which means that a unit can be selected more than once. In with-replacement sampling, the number of hits refers to the number of times a unit is selected.

In probability proportional to size (PPS) sampling, a unit’s selection probability is proportional to its size measure. PROC SURVEYSELECT provides the following methods that select units with probability proportional to size (PPS): PPS sampling without replacement, PPS sampling with replacement, PPS systematic sampling, PPS sequential sampling, Brewer’s method, Murthy’s method, and Sampford’s method. PPS sampling is often used in cluster sampling, where you select clusters (or groups of sampling units) of varying size in the first stage of selection. For example, clusters may be schools, hospitals, or geographical areas, and the final sampling units may be students, patients, or citizens. Cluster sampling can provide efficiencies in frame construction and other survey operations. Refer to Lohr (1999), Kalton (1983), Kish (1965), and the other references cited in the following sections for more information.

All the probability sampling methods provided by PROC SURVEYSELECT use random numbers in their selection algorithms, as described in the following sections.
and in the references cited. PROC SURVEYSELECT uses a uniform random number function to generate streams of pseudo-random numbers from an initial starting point, or seed. You can use the SEED= option to specify the initial seed. If you do not specify the SEED= option, PROC SURVEYSELECT uses the time of day from the computer’s clock to obtain the initial seed. PROC SURVEYSELECT generates uniform random numbers according to the method of Fishman and Moore (1982), using a prime modulus multiplicative generator with modulus $2^{31}$ and multiplier 397204094. PROC SURVEYSELECT uses the same uniform random number generator as the RANUNI function. For more information on the RANUNI function, see the SAS Language Reference: Dictionary.

The following sections give detailed descriptions of the sample selection methods available in PROC SURVEYSELECT. In these sections, $n_h$ denotes the sample size (the number of units in the sample) for stratum $h$, and $N_h$ denotes the population size (number of units in the population) for stratum $h$, for $h = 1, 2, \ldots, H$. When the sample design is not stratified, $n$ denotes the sample size, and $N$ denotes the population size. For PPS sampling, $M_{hi}$ represents the size measure for unit $i$ in stratum $h$, $M_h$ is the total of all size measures for the population of stratum $h$, and $Z_{hi} = M_{hi}/M_h$ is the relative size of unit $i$ in stratum $h$.

**Simple Random Sampling**

The method of simple random sampling (METHOD=SRS) selects units with equal probability and without replacement. Each possible sample of $n$ different units out of $N$ has the same probability of being selected. The selection probability for each individual unit equals $n/N$. When you request stratified sampling with a STRATA statement, PROC SURVEYSELECT selects samples independently within strata. The selection probability for a unit in stratum $h$ equals $n_h/N_h$ for stratified simple random sampling.

By default, PROC SURVEYSELECT uses Floyd’s ordered hash table algorithm for simple random sampling. This algorithm is fast, efficient, and appropriate for large data sets. Refer to Bentley and Floyd (1987) and Bentley and Knuth (1986).

If there is not enough memory available for Floyd’s algorithm, PROC SURVEYSELECT switches to the sequential algorithm of Fann, Muller, and Rezucha (1962), which requires less memory but may require more time to select the sample. When SURVEYSELECT uses the alternative sequential algorithm, it writes a note to the log. To request the sequential algorithm, even if enough memory is available for Floyd’s algorithm, you can specify METHOD=SRS2 in the PROC SURVEYSELECT statement.

**Unrestricted Random Sampling**

The method of unrestricted random sampling (METHOD=URS) selects units with equal probability and with replacement. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of selections or hits for each unit equals $n/N$ when sampling without stratification. For stratified sampling, the expected number of hits for a unit in stratum $h$ equals $n_h/N_h$. Note that the expected number of hits exceeds one when the sample size $n$ is greater than the population size $N$. 
For unrestricted random sampling, by default, the output data set contains one observation for each distinct unit selected for the sample, together with a variable `NumberHits` that gives the number of times the observation was selected. But if you specify the `OUTHITS` option, then the output data set contains a separate observation for each selection, so that a unit selected three times, e.g., is represented by three observations in the output data set. For information on the contents of the output data set, see the section “Output Data Set” on page 4456.

**Systematic Random Sampling**

The method of systematic random sampling (METHOD=SYS) selects units at a fixed interval throughout the sampling frame or stratum after a random start. If you specify the sample size (or the stratum sample sizes) with the `SAMPSize=` option, PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals \( \frac{N}{n} \), or \( \frac{N_h}{n_h} \) for stratified sampling. The selection probability for each unit equals \( \frac{n}{N} \), or \( \frac{n_h}{N_h} \) for stratified sampling. If you specify the sampling rate (or the stratum sampling rates) with the `SAMPRate=` option, PROC SURVEYSELECT uses the inverse of the rate as the interval for systematic selection. The selection probability for each unit equals the specified rate.

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the `CONTROL` statement to order the input data set by the `CONTROL` variables before sample selection. If you also use a `STRAA` statement, PROC SURVEYSELECT sorts by the `CONTROL` variables within strata. If you do not specify a `CONTROL` statement, PROC SURVEYSELECT applies systematic selection to the observations in the order in which they appear in the input data set.

**Sequential Random Sampling**

If you specify the option METHOD=SEQ and do not include a SIZE statement, PROC SURVEYSELECT uses the equal probability version of Chromy’s method for sequential random sampling. This method selects units sequentially with equal probability and without replacement. Refer to Chromy (1979) and Williams and Chromy (1980). See the section “PPS Sequential Sampling” on page 4452 for a description of Chromy’s PPS selection method.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the `CONTROL` statement to sort the input data set by the `CONTROL` variables before sample selection. If you also use a `STRAA` statement, PROC SURVEYSELECT sorts by the `CONTROL` variables within strata. By default, the procedure uses hierarchic serpentine ordering for sorting. If you specify the `SORT=NEST` option, the procedure uses nested sorting. See the section “Sorting by `CONTROL` Variables” on page 4445 for descriptions of serpentine and nested sorting. If you do not specify a `CONTROL` statement, PROC SURVEYSELECT applies sequential selection to the observations in the order in which they appear in the input data set.

Following Chromy’s method of sequential selection, PROC SURVEYSELECT randomly chooses a starting unit from the entire stratum (or frame, if the design is not
stratified). Using this unit as the first one, the procedure treats the stratum units as a closed loop. This is done so that all pairwise (joint) selection probabilities are positive and an unbiased variance estimator can be obtained. The procedure numbers units sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, PROC SURVEYSELECT accumulates the expected number of selections or hits, where the expected number of selections $ES_{hi}$ equals $n_h/N_h$ for all units $i$ in stratum $h$. The procedure computes

$$I_{hi} = \text{Int} \left( \sum_{j=1}^{i} ES_{hj} \right) = \text{Int} \left( i \frac{n_h}{N_h} \right)$$

$$F_{hi} = \text{Frac} \left( \sum_{j=1}^{i} ES_{hj} \right) = \text{Frac} \left( i \frac{n_h}{N_h} \right)$$

where $\text{Int}$ denotes the integer part of the number, and $\text{Frac}$ denotes the fractional part.

Considering each unit sequentially, Chromy’s method determines whether unit $i$ is selected by comparing the total number of selections for the first $i - 1$ units,

$$T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj}$$

with the value of $I_{h(i-1)}$.

If $T_{h(i-1)} = I_{h(i-1)}$, Chromy’s method determines whether or not unit $i$ is selected as follows. If $F_{hi} = 0$ or $F_{h(i-1)} > F_{hi}$, then unit $i$ is selected with certainty. Otherwise, unit $i$ is selected with probability

$$\frac{(F_{hi} - F_{h(i-1)})}{(1 - F_{h(i-1)})}$$

If $T_{h(i-1)} = I_{h(i-1)} + 1$, Chromy’s method determines whether or not unit $i$ is selected as follows. If $F_{hi} = 0$ or $F_{hi} > F_{h(i-1)}$, then the unit is not selected. Otherwise, unit $i$ is selected with probability

$$F_{hi} / F_{h(i-1)}$$

**PPS Sampling without Replacement**

If you specify the option `METHOD=PPS`, PROC SURVEYSELECT selects units with probability proportional to size and without replacement. The selection probability for unit $i$ in stratum $h$ equals $n_h Z_{hi}$. The procedure uses the Hanurav-Vijayan algorithm for PPS selection without replacement. Hanurav (1967) introduced this algorithm for the selection of two units per stratum, and Vijayan (1968) generalized it for the selection of more than two units. The algorithm enables computation of joint
selection probabilities and provides joint selection probability values that usually ensure nonnegativity and stability of the Sen-Yates-Grundy variance estimator. Refer to Fox (1989), Golmant (1990), and Watts (1991) for details.

Notation in the remainder of this section drops the stratum subscript \( h \) for simplicity, but selection is still done independently within strata if you specify a stratified design. For a stratified design, \( n \) now denotes the sample size for the current stratum, \( N \) denotes the stratum population size, and \( M_i \) denotes the size measure for unit \( i \) in the stratum. If the design is not stratified, this notation applies to the entire sampling frame.

According to the Hanurav-Vijayan algorithm, PROC SURVEYSELECT first orders units within the stratum in ascending order by size measure, so that \( M_1 \leq M_2 \leq \ldots \leq M_N \). Then the procedure selects the PPS sample of \( n \) observations as follows:

1. The procedure randomly chooses one of the integers \( 1, 2, \ldots, n \) with probability \( \theta_1, \theta_2, \ldots, \theta_n \), where
   \[
   \theta_i = n \left( Z_{N-n+i+1} - Z_{N-n+i} \right) \frac{T + i Z_{N-n+1}}{T}
   \]
   \[
   Z_j = M_j / M, \quad T = \sum_{j=1}^{N-n} Z_j, \quad \text{and, by definition, } Z_{N+1} = 1/n \text{ to ensure that } \sum_{i=1}^{n} \theta_i = 1.
   \]

2. If \( i \) is the integer selected in step 1, the procedure includes the last \( (n-i) \) units of the stratum in the sample, where the units are ordered by size measure as described previously. The procedure then selects the remaining \( i \) units according to steps 3 through 6 below.

3. The procedure defines new normed size measures for the remaining \( (N-n+i) \) stratum units that were not selected in steps 1 and 2:
   \[
   Z_j^* = \frac{Z_j}{(T + i Z_{N-n+1})} \quad \text{for } j = 1, \ldots, N-n+1
   \]
   \[
   Z_j^* = \frac{Z_{N-n+1}}{(T + i Z_{N-n+1})} \quad \text{for } j = N-n+2, \ldots, N-n+i
   \]

4. The procedure selects the next unit from the first \( (N-n+1) \) stratum units with probability proportional to \( a_j(1) \), where
   \[
   a_1(1) = i Z_1^*
   \]
   \[
   a_j(1) = i Z_j^* \prod_{k=1}^{j-1} \left[ 1 - (i-1) P_k \right] \quad \text{for } j = 2, \ldots, N-n+1
   \]
   and \( P_k = M_k / (M_{k+1} + M_{k+2} + \cdots + M_{N-n+i}) \).

5. If stratum unit \( j_1 \) is the unit selected in step 4, then the procedure selects the next unit from units \( j_1 + 1 \) through \( N-n+2 \) with probability proportional to \( a_j(2,j_1) \), where
   \[
   a_{j_1+1}(2,j_1) = (i-1) Z_{j_1+1}^*
   \]
   \[
   a_j(2,j_1) = (i-1) Z_j^* \prod_{k=j_1+1}^{j-1} \left[ 1 - (i-2) P_k \right] \quad \text{for } j = j_1 + 2, \ldots, N-n+2
   \]

6. The procedure repeats step 5 until all \( n \) sample units are selected.
If you request the JTPROBS option, PROC SURVEYSELECT computes the joint selection probabilities for all pairs of selected units in each stratum. The joint selection probability for units $i$ and $j$ in the stratum equals

$$P_{(ij)} = \sum_{r=1}^{n} \theta_r K_{ij}^{(r)}$$

where

$$K_{ij}^{(r)} = \begin{cases} 1 & N - n + r < i \leq N - 1 \\ r \frac{Z_{N-n+1}}{(T + r Z_{N-n+1})} & N - n < i \leq N - n + r, \ j > N - n + r \\ r \frac{Z_i}{(T + r Z_{N-n+1})} & 1 \leq i \leq N - n, \ j > N - n + r \\ \pi_{ij}^{(r)} & j \leq N - n + r \end{cases}$$

and

$$\pi_{ij}^{(r)} = \frac{r(r - 1)}{2} P_i Z_j \prod_{k=1}^{i-1} (1 - P_k)$$

where $P_k = M_k/(M_{k+1} + M_{k+2} + \cdots + M_{N-n+r})$.

**PPS Sampling with Replacement**

If you specify the option METHOD=PPS_WR, PROC SURVEYSELECT selects units with probability proportional to size and with replacement. The procedure makes $n_h$ independent random selections from the stratum of $N_h$ units, selecting with probability $Z_{hi} = M_{hi}/M_h$. Because units are selected with replacement, a unit can be selected for the sample more than once. The expected number of selections or hits for unit $i$ in stratum $h$ equals $n_h Z_{hi}$. If you request the JTPROBS option, PROC SURVEYSELECT computes the joint expected number of hits for all pairs of selected units in each stratum. The joint expected number of hits for units $i$ and $j$ in stratum $h$ equals

$$P_{h(ij)} = \begin{cases} n_h(n_h - 1) Z_{hi} Z_{hj} & \text{for } j \neq i \\ n_h(n_h - 1) Z_{hi} Z_{hi}/2 & \text{for } j = i \end{cases}$$

**PPS Systematic Sampling**

If you specify the option METHOD=PPS_SYS, PROC SURVEYSELECT selects units by systematic random sampling with probability proportional to size. Systematic sampling selects units at a fixed interval throughout the stratum or sampling frame after a random start. PROC SURVEYSELECT uses a fractional interval to provide exactly the specified sample size. The interval equals $M_h/n_h$ for stratified sampling and $M/n$ for sampling without stratification. Depending on the sample size and the values of the size measures, it may be possible for a unit to be selected more
than once. The expected number of selections or hits for unit $i$ in stratum $h$ equals $n_h M_{hi} / M_h = n_h Z_{hi}$. Refer to Cochran (1977, pp. 265–266) and Madow (1949).

Systematic random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum at equal intervals, thus providing implicit stratification. You can use the `CONTROL` statement to order the input data set by the `CONTROL` variables before sample selection. If you also use a `STRATA` statement, `PROC SURVEYSELECT` sorts by the `CONTROL` variables within strata. If you do not specify a `CONTROL` statement, `PROC SURVEYSELECT` applies systematic selection to the observations in the order in which they appear in the input data set.

**PPS Sequential Sampling**

If you specify the option `METHOD=PPS_SEQ`, `PROC SURVEYSELECT` uses Chromy’s method of sequential random sampling. Refer to Chromy (1979) and Williams and Chromy (1980). Chromy’s method selects units sequentially with probability proportional to size and with minimum replacement. Selection with minimum replacement means that the actual number of hits for a unit can equal the integer part of the expected number of hits for that unit, or the next largest integer. This can be compared to selection without replacement, where each unit can be selected only once, so the number of hits can equal 0 or one. The other alternative is selection with replacement, where there is no restriction on the number of hits for each unit, so the number of hits can equal 0, 1, ..., $n_h$, where $n_h$ is the stratum sample size.

Sequential random sampling controls the distribution of the sample by spreading it throughout the sampling frame or stratum, thus providing implicit stratification according to the order of units in the frame or stratum. You can use the `CONTROL` statement to sort the input data set by the `CONTROL` variables before sample selection. If you also use a `STRATA` statement, `PROC SURVEYSELECT` sorts by the `CONTROL` variables within strata. By default, the procedure uses hierarchic serpentine ordering to sort the sampling frame by the `CONTROL` variables within strata. If you specify the `SORT=NEST` option, the procedure uses nested sorting. See the section “Sorting by `CONTROL` Variables” on page 4445 for descriptions of serpentine and nested sorting. If you do not specify a `CONTROL` statement, `PROC SURVEYSELECT` applies sequential selection to the observations in the order in which they appear in the input data set.

According to Chromy’s method of sequential selection, `PROC SURVEYSELECT` first chooses a starting unit randomly from the entire stratum, with probability proportional to size. The procedure uses this unit as the first one and treats the stratum observations as a closed loop. This is done so that all pairwise (joint) expected number of hits are positive and an unbiased variance estimator can be obtained. The procedure numbers observations sequentially from the random start to the end of the stratum and then continues from the beginning of the stratum until all units are numbered.

Beginning with the randomly chosen starting unit, Chromy’s method partitions the ordered stratum sampling frame into $n_h$ zones of equal size. There is one selection from each zone and a total of $n_h$ selections or hits, although fewer than $n_h$ distinct
Sample Selection Methods

units may be selected. Beginning with the random start, the procedure accumulates the expected number of hits and computes

\[ ES_{hi} = n_h Z_{hi} \]

\[ I_{hi} = \text{Int} \left( \sum_{j=1}^{i} ES_{hj} \right) \]

\[ F_{hi} = \text{Frac} \left( \sum_{j=1}^{i} ES_{hj} \right) \]

where \( ES_{hi} \) represents the expected number of hits for unit \( i \) in stratum \( h \); \( \text{Int} \) denotes the integer part of the number; and \( \text{Frac} \) denotes the fractional part.

Considering each unit sequentially, Chromy’s method determines the actual number of hits for unit \( i \) by comparing the total number of hits for the first \( i - 1 \) units,

\[ T_{h(i-1)} = \sum_{j=1}^{i-1} S_{hj} \]

with the value of \( I_{h(i-1)} \).

If \( T_{h(i-1)} = I_{h(i-1)} \), Chromy’s method determines the total number of hits for the first \( i \) units as follows. If \( F_{hi} = 0 \) or \( F_{h(i-1)} > F_{hi} \), then \( T_{hi} = I_{hi} \). Otherwise, \( T_{hi} = I_{hi} + 1 \) with probability

\[ \frac{(F_{hi} - F_{h(i-1)})}{(1 - F_{h(i-1)})} \]

And the number of hits for unit \( i \) equals \( T_{hi} - T_{h(i-1)} \).

If \( T_{h(i-1)} = I_{h(i-1)} + 1 \), Chromy’s method determines the total number of hits for the first \( i \) units as follows. If \( F_{hi} = 0 \), then \( T_{hi} = I_{hi} \). If \( F_{hi} > F_{h(i-1)} \), then \( T_{hi} = I_{hi} + 1 \). Otherwise, \( T_{hi} = I_{hi} + 1 \) with probability

\[ \frac{F_{hi}}{F_{h(i-1)}} \]

Brewer’s PPS Method

Brewer’s method (METHOD=PPS_BREWER) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit \( i \) in stratum \( h \) equals \( 2M_{hi}/M_h = 2Z_{hi} \).
Brewer’s algorithm first selects a unit with probability
\[
\frac{Z_{hi} (1 - Z_{hi})}{D_h (1 - 2Z_{hi})}
\]
where
\[
D_h = \sum_{i=1}^{N_h} \frac{Z_{hi} (1 - Z_{hi})}{1 - 2Z_{hi}}
\]
Then a second unit is selected from the remaining units with probability
\[
\frac{Z_{hj}}{1 - Z_{hi}}
\]
where unit \(i\) is the first unit selected. The joint selection probability for units \(i\) and \(j\) in stratum \(h\) equals
\[
P_{h(ij)} = \frac{2 Z_{hi} Z_{hj}}{D_h} \left( \frac{1 - Z_{hi} - Z_{hj}}{(1 - 2Z_{hi}) (1 - 2Z_{hj})} \right)
\]
Brewer’s method requires that the relative size \(Z_{hi}\) be less than 0.5 for all units. Refer to Cochran (1977, pp. 261–263) and Brewer (1963). Brewer’s method yields the same selection probabilities and joint selection probabilities as Durbin’s method. Refer to Cochran (1977) and Durbin (1967).

**Murthy’s PPS Method**

Murthy’s method (METHOD=PPS_MURTHY) selects two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit \(i\) in stratum \(h\) equals
\[
P_{hi} = Z_{hi} [1 + K - (Z_{hi}/(1 - Z_{hi})]
\]
where \(Z_{hi} = M_{hi}/M_h\), and
\[
K = \sum_{j=1}^{N} [Z_{hj}/(1 - Z_{hj})]
\]
Murthy’s algorithm first selects a unit with probability \(Z_{hi}\). Then a second unit is selected from the remaining units with probability \(Z_{hj} / (1 - Z_{hi})\), where unit \(i\) is the first unit selected. The joint selection probability for units \(i\) and \(j\) in stratum \(h\) equals
\[
P_{h(ij)} = Z_{hi} Z_{hj} \frac{2 - Z_{hi} - Z_{hj}}{(1 - Z_{hi}) (1 - Z_{hj})}
\]
Refer to Cochran (1977, pp. 263–265) and Murthy (1957).
**Sampford’s PPS Method**

Sampford’s method (METHOD=PPS – SAMPFORD) is an extension of Brewer’s method that selects more than two units from each stratum, with probability proportional to size and without replacement. The selection probability for unit \(i\) in stratum \(h\) equals

\[
P_{hi} = n_h \frac{M_{hi}}{M_h} = n_h Z_{hi}
\]

Sampford’s method first selects a unit from stratum \(h\) with probability \(Z_{hi}\). Then subsequent units are selected with probability proportional to

\[
\frac{Z_{hi}}{1 - n_h Z_{hi}}
\]

and with replacement. If the same unit appears more than once in the sample of size \(n_h\), then Sampford’s algorithm rejects that sample and selects a new sample. The sample is accepted if it contains \(n_h\) distinct units.

The joint selection probability for units \(i\) and \(j\) in stratum \(h\) equals

\[
P_{h(ij)} = K_h \lambda_i \lambda_j \sum_{t=2}^{n_h} \left[ t - n_h (P_{hi} + P_{h(j)}) L_{n_h-t(ij)} \right] / n_h^{t-2}
\]

where

\[
\lambda_i = \frac{Z_{hi}}{1 - n_h Z_{hi}}
\]

\[
L_m = \sum_{S(m)} \lambda_{i_1} \lambda_{i_2} \cdots \lambda_{i_m}
\]

where \(S(m)\) denotes all possible samples of size \(m\), for \(m = 1, 2, \ldots, N_h\). The sum \(L_m(ij)\) is defined similarly to \(L_m\) but sums over all possible samples of size \(m\) that do not include units \(i\) and \(j\), and

\[
K_h = \left( \sum_{t=1}^{n_h} t L_{n_h-t} / n_h^t \right)^{-1}
\]

Sampford’s method requires that the relative size \(Z_{hi}\) be less than \(1/n_h\) for all units. Refer to Cochran (1977, pp. 262–263) and Sampford (1967).
Output Data Set

PROC SURVEYSELECT creates a SAS data set that contains the sample of selected units. You can specify the name of this output data set with the OUT= option in the PROC SURVEYSELECT statement. If you omit the OUT= option, the data set is named DATA_n, where n is the smallest integer that makes the name unique.

By default, the output data set contains one observation for each unit selected for the sample. But if you specify the OUTALL option, the output data set includes all observations from the input data set. With OUTALL, the output data set also contains a variable to indicate each observation’s selection status. The variable Selected equals 1 for an observation selected for the sample, and equals 0 for an observation not selected. The OUTALL option is available only for equal probability selection methods.

If you specify the OUTHITS option for methods that may select the same unit more than once (that is, methods that select with replacement or with minimum replacement), the output data set contains a separate observation for each selection. If you do not specify the OUTHITS option, the output data set contains only one observation for each selected unit, even if the unit is selected more than once, and the variable NumberHits contains the number of hits or selections for that unit.

The output data set contains design information and selection statistics, depending on the selection method and output options you specify. The output data set can include the following variables:

- **Selected**, which indicates whether or not the observation is selected for the sample. This variable is included if you specify the OUTALL option. It equals 1 for an observation selected for the sample, and it equals 0 for an observation not selected.
- **STRATA variables**, which you specify in the STRATA statement
- **Replicate**, which is the sample replicate number. This variable is included when you request replicated sampling with the REP= option.
- **ID variables**, which you name in the ID statement
- **CONTROL variables**, which you specify in the CONTROL statement
- **Zone**, which is the selection zone. This variable is included for METHOD=PPS_SEQ.
- **SIZE variable**, which you specify in the SIZE statement
- **AdjustedSize**, which is the adjusted size measure. This variable is included if you request adjusted sizes with the MINSIZE= option or the MAXSIZE= option.
- **Certain**, which indicates certainty selection. This variable is included if you specify the CERTSIZE= option. It equals 1 for units included with certainty because their size measures exceed the certainty size measure. Otherwise, it equals 0.
- **NumberHits**, which is the number of hits or selections. This variable is included for selection methods that are with replacement or with minimum replacement (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ).

The output data set includes the following variables if you request a PPS selection method or if you specify the STATS option for other methods:

- **ExpectedHits**, which is the expected number of hits or selections. This variable is included for selection methods that are with replacement or with minimum replacement, and so may select the same unit more than once (METHOD=URS, METHOD=PPS_WR, METHOD=PPS_SYS, and METHOD=PPS_SEQ).
- **SelectionProb**, which is the probability of selection. This variable is included for selection methods that are without replacement.
- **SamplingWeight**, which is the sampling weight. This variable equals the inverse of **ExpectedHits** or **SelectionProb**.

For METHOD=PPS_BREWER and METHOD=PPS_MURTHY, which select two units from each stratum with probability proportional to size, the output data set contains the following variable:

- **JtSelectionProb**, which is the joint probability of selection for the two units selected from the stratum

If you request the JTPROBS option to compute joint probabilities of selection for METHOD=PPS or METHOD=PPS_SAMPFORD, then the output data set contains the following variables:

- **Unit**, which is an identification variable that numbers the selected units sequentially within each stratum
- **JtProb_1**, **JtProb_2**, **JtProb_3**, …, where the variable **JtProb_1** contains the joint probability of selection for the current unit and unit 1. Similarly, **JtProb_2** contains the joint probability of selection for the current unit and unit 2, and so on.

If you request the JTPROBS option for METHOD=PPS_WR, then the output data set contains the following variables:

- **Unit**, which is an identification variable that numbers the selected units sequentially within each stratum
- **JtHits_1**, **JtHits_2**, **JtHits_3**, …, where the variable **JtHits_1** contains the joint expected number of hits for the current unit and unit 1. Similarly, **JtHits_2** contains the joint expected number of hits for the current unit and unit 2, and so on.
If you request the OUTSIZE option, the output data set contains the following variables. If you specify a STRATA statement, the output data set includes stratum-level values of these variables. Otherwise, the output data set contains population-level values of these variables.

- **MinimumSize**, which is the minimum size measure specified with the MINSIZE= option. This variable is included if you request the MINSIZE= option.
- **MaximumSize**, which is the maximum size measure specified with the MAXSIZE= option. This variable is included if you request the MAXSIZE= option.
- **CertaintySize**, which is the certainty size measure specified with the CERTSIZE= option. This variable is included if you request the CERTSIZE= option.
- **Total**, which is the total number of sampling units in the stratum. This variable is included if there is no SIZE statement.
- **TotalSize**, which is the total of size measures in the stratum. This variable is included if there is a SIZE statement.
- **TotalAdjSize**, which is the total of adjusted size measures in the stratum. This variable is included if there is a SIZE statement and if you request adjusted sizes with the MAXSIZE= option or the MINSIZE= option.
- **SamplingRate**, which is the sampling rate. This variable is included if you specify the SAMPRATE= option.
- **SampleSize**, which is the sample size. This variable is included if you specify the SAMPSIZE= option, or if you specify METHOD=PPS_BREWER or METHOD=PPS_MURTHY, which select two units from each stratum.

If you request the OUTSEED option, the output data set contains the following variable:

- **InitialSeed**, which is the initial seed for the stratum.

**Displayed Output**

By default, PROC SURVEYSELECT displays two tables that summarize the sample selection. You can suppress display of these tables by using the NOPRINT option.

PROC SURVEYSELECT creates an output data set that contains the units selected for the sample. The procedure does not display this output data set. Use PROC PRINT, PROC REPORT, or any other SAS reporting tool to display the output data set.
PROC SURVEYSELECT displays the following information in the “Sample Selection Method” table:

- Selection Method
- Size Measure variable, if you specify a SIZE statement
- Minimum Size Measure, if you specify the MINSIZE= option
- Maximum Size Measure, if you specify the MAXSIZE= option
- Certainty Size Measure, if you specify the CERTSIZE= option
- Strata Variables, if you specify a STRATA statement
- Control Variables, if you specify a CONTROL statement
- type of Control Sorting, Serpentine or Nested, if you specify a CONTROL statement

PROC SURVEYSELECT displays the following information in the “Sample Selection Summary” table:

- Input Data Set name
- Sorted Data Set name, if you specify the OUTSORT= option
- Random Number Seed
- Sample Size or Stratum Sample Size, if you specify the SAMPSIZE=n option
- Sample Size Data Set, if you specify the SAMPSIZE=SAS-data-set option
- Sampling Rate or Stratum Sampling Rate, if you specify the SAMPRATE=r option
- Sampling Rate Data Set, if you specify the SAMPRATE=SAS-data-set option
- Minimum Sample Size or Stratum Minimum Sample Size, if you specify the NMIN= option with the SAMPRATE= option
- Maximum Sample Size or Stratum Maximum Sample Size, if you specify the NMAX= option with the SAMPRATE= option
- Selection Probability, if you specify METHOD=SRS, METHOD=SYS, or METHOD=SEQ and do not specify a STRATA statement
- Expected Number of Hits, if you specify METHOD=URS and do not specify a STRATA statement
- Sampling Weight for equal probability selection methods (METHOD=SRS, METHOD=URS, METHOD=SYS, METHOD=SEQ) if you do not specify a STRATA statement
- Number of Strata, if you specify a STRATA statement
- Number of Replicates, if you specify the REP= option
- Total Sample Size, if you specify a STRATA statement or the REP= option
- Output Data Set name
**ODS Table Names**

PROC SURVEYSELECT assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

<table>

</tbody>
</table>

**Examples**

**Example 72.1. Replicated Sampling**

This example uses the **Customers** data set from the section “Getting Started” on page 4422. The data set **Customers** contains an Internet service provider’s current subscribers, and the service provider wants to select a sample from this population for a customer satisfaction survey.

This example illustrates replicated sampling, which selects multiple samples from the survey population according to the same design. You can use replicated sampling to provide a simple method of variance estimation, or to evaluate variable nonsampling errors such as interviewer differences. Refer to Lohr (1999), Kish (1965, 1987), and Kalton (1983) for information on replicated sampling.

This design includes four replicates, each with a sample size of 50 customers. The sampling frame is stratified by **State** and sorted by **Type** and **Usage** within strata. Customers are selected by sequential random sampling with equal probability within strata. The following PROC SURVEYSELECT statements select a probability sample of customers from the **Customers** data set using this design.

```plaintext
title1 'Customer Satisfaction Survey';
title2 'Replicated Sampling';
proc surveyselect data=Customers
   method=seq n=(8 12 20 10)
   rep=4
   seed=40070 out=SampleRep;
   strata State;
   control Type Usage;
run;
```

The STRATA statement names the stratification variable **State**. The CONTROL statement names the control variables **Type** and **Usage**. In the PROC SURVEYSELECT statement, the METHOD=SEQ option requests sequential random sampling. The REP=4 option specifies four replicates of this sample. The N=(8 12 20 10) option specifies the stratum sample sizes for each replicate. The
N= option lists the stratum sample sizes in the same order as the strata appear in the Customers data set, which has been sorted by State. The sample size of eight customers corresponds to the first stratum, State = ‘AL’. The sample size 12 corresponds to the next stratum, State = ‘FL’, and so on. The SEED=40070 option specifies ‘40070’ as the initial seed for random number generation.

Output 72.1.1 displays the output from PROC SURVEYSELECT, which summarizes the sample selection. A total of 200 customers is selected in four replicates. PROC SURVEYSELECT selects each replicate using sequential random sampling within strata determined by State. The sampling frame Customers is sorted by control variables Type and Usage within strata, according to hierarchic serpentine sorting. The output data set SampleRep contains the sample.

**Output 72.1.1. Sample Selection Summary**

</table>

Output 72.1.2 displays the 32 sample customers of the first stratum (State = ‘AL’) from the output data set SampleRep, which includes the entire sample of 200 customers. The variable SelectionProb contains the selection probability, and SamplingWeight contains the sampling weight. Since customers are selected with equal probability within strata in this design, all customers in the same stratum have the same selection probability. These selection probabilities and sampling weights apply to a single replicate, and the variable Replicate contains the sample replicate number.
Example 72.2. PPS Selection of Two Units Per Stratum

A state health agency plans to conduct a state-wide survey of a variety of different hospital services. The agency plans to select a probability sample of individual discharge records within hospitals using a two-stage sample design. First stage units are hospitals, and second stage units are patient discharges during the study time period. Hospitals are stratified first according to geographic region and then by rural/urban type and size of hospital. Two hospitals are selected from each stratum with probability proportional to size. This example describes hospital selection for this survey using PROC SURVEYSELECT.

The data set HospitalFrame contains all hospitals in the first geographical region of this state.

```sas
data HospitalFrame;
  input Hospital$ Type$ SizeMeasure @@;
  if (SizeMeasure < 20) then Size='Small ';
    else if (SizeMeasure < 50) then Size='Medium';
    else Size='Large ';
  datalines;
  034 Rural 0.870 107 Rural 1.316
  079 Rural 2.127 223 Rural 3.960
  236 Rural 5.279 165 Rural 5.893
  086 Rural 0.501 141 Rural 11.528
  042 Urban 3.104 124 Urban 4.033
  006 Urban 4.249 261 Urban 4.376
  195 Urban 5.024 190 Urban 10.373
  038 Urban 17.125 083 Urban 40.382
  259 Urban 44.942 129 Urban 46.702
  133 Urban 46.992 218 Urban 48.231
  026 Urban 61.460 058 Urban 65.931
  119 Urban 66.352
;
```

In the SAS data set HospitalFrame, the variable Hospital identifies the hospital. The variable Type equals ‘Urban’ if the hospital is located in an urbanized area, and ‘Rural’ otherwise. The variable SizeMeasure contains the hospital’s size measure, which is constructed from past data on service utilization for the hospital together with the desired sampling rates for each service. This size measure reflects the amount of relevant survey information expected from the hospital. Refer to Drummond et al. (1982) for details on this type of size measure. The variable Size equals ‘Small’, ‘Medium’, or ‘Large’, depending on the value of the hospital’s size measure.

The following PROC PRINT statements display the data set Hospital Frame.

```sas
  title1 'Hospital Utilization Survey';
  title2 'Sampling Frame, Region 1';
  proc print data=HospitalFrame;
  run;
```
Output 72.2.1. Sampling Frame

</table>

The following PROC SURVEYSELECT statements select a probability sample of hospitals from the HospitalFrame data set, using a stratified design with PPS selection of two units from each stratum.

```
title1 'Hospital Utilization Survey';
proc surveyselect data=HospitalFrame
   method=pps_brewer
   seed=48702 out=SampleHospitals;
   size SizeMeasure;
   strata Type Size notsorted;
run;
```

The STRATA statement names the stratification variables Type and Size. The NOTSORTED option specifies that observations with the same STRATA variable values are grouped together but are not necessarily sorted in alphabetical or increasing numerical order. In the HospitalFrame data set, Size = ‘Small’ precedes Size = ‘Medium’.

In the PROC SURVEYSELECT statement, the METHOD=PPS_BREWER option requests sample selection by Brewer’s method, which selects two units per stratum with probability proportional to size. The SEED=48702 option specifies ‘48702’ as the initial seed for random number generation. The SIZE statement specifies the size measure variable. It is not necessary to specify the sample size with the N= option, since Brewer’s method always selects two units from each stratum.
Output 72.2.2 displays the output from PROC SURVEYSELECT. A total of 8 hospitals were selected from the 4 strata. The data set SampleHospitals contains the selected hospitals.

Output 72.2.2. Sample Selection Summary

```
Hospital Utilization Survey

```

The variable SelectionProb contains the selection probability for each hospital in the sample. The variable JtSelectionProb contains the joint probability of selection for the two sample hospitals in the same stratum. The variable SamplingWeight contains the sampling weight component for this first stage of the design. The final-stage weight components, which correspond to patient record selection within hospitals, can be multiplied by the hospital weight components to obtain the overall sampling weights.
Example 72.3. PPS (Dollar-Unit) Sampling

A small company wants to audit employee travel expenses in an effort to improve the expense reporting procedure and possibly reduce expenses. The company does not have resources to examine all expense reports and wants to use statistical sampling to objectively select expense reports for audit.

The data set TravelExpense contains the dollar amount of all employee travel expense transactions during the past month.

data TravelExpense;
  input ID$ Amount @@;
  if (Amount < 500) then Level='1_Low';
  else if (Amount > 1500) then Level='3_High';
  else Level='2_Avg';
datalines;

   506 895.80 239 620.10 011 420.18
   672 979.66 142 810.25 738 670.85
   192 314.58 243 87.50 263 1893.40
   496 753.30 332 540.65 486 2580.35
   614 230.56 654 185.60 308 688.43
   784 505.14 017 205.48 162 650.42
   289 1348.34 691 30.50 545 2214.80
   517 940.35 382 217.85 024 142.90
   478 806.90 107 560.72
;

In the SAS data set TravelExpense, the variable ID identifies the travel expense report. The variable Amount contains the dollar amount of the reported expense. The variable Level equals ‘1_Low’, ‘2_Avg’, or ‘3_High’, depending on the value of Amount.

In the sample design for this audit, expense reports are stratified by Level. This ensures that each of these expense levels is included in the sample and also permits a disproportionate allocation of the sample, selecting proportionately more of the expense reports from the higher levels. Within strata, the sample of expense reports is selected with probability proportional to the amount of the expense, thus giving a greater chance of selection to larger expenses. In auditing terms, this is known as monetary-unit sampling. Refer to Wilburn (1984).

PROC SURVEYSELECT requires that the input data set be sorted by the STRATA variables. The following PROC SORT statements sort the TravelExpense data set by the stratification variable Level.

    proc sort data=TravelExpense;
      by Level;
    run;
The following PROC PRINT statements display the sampling frame data set `TravelExpense`, which contains 41 observations.

```snip
title1 'Travel Expense Audit';
proc print data=TravelExpense;
run;
```

The following PROC SURVEYSELECT statements select a probability sample of expense reports from the TravelExpense data set using the stratified design with PPS selection within strata.

```
title1 'Travel Expense Audit';
proc surveyselect data=TravelExpense
   method=pps n=(6 10 4)
   seed=47279 out=AuditSample;
   size Amount;
   strata Level;
run;
```

The STRATA statement names the stratification variable Level. The SIZE statement specifies the size measure variable Amount. In the PROC SURVEYSELECT statement, the METHOD=PPS option requests sample selection with probability proportional to size and without replacement. The N=(6 10 4) option specifies the stratum sample sizes, listing the sample sizes in the same order that the strata appear in the TravelExpense data set. The sample size of 6 corresponds to the first stratum, Level = ‘1_Low’, the sample size of 10 corresponds to the second stratum, Level = ‘2_Avg’, and 4 corresponds to the last stratum, Level = ‘3_High’. The SEED=47279 option specifies ‘47279’ as the initial seed for random number generation.

Output 72.3.2 displays the output from PROC SURVEYSELECT. A total of 20 expense reports is selected for audit. The data set AuditSample contains the sample of travel expense reports.

References

The TPHREG procedure, experimental in this release, includes most of the functionality of the PHREG procedure (see Chapter 54, “The PHREG Procedure”) with the additional benefits of the CLASS statement. The CLASS statement enables you to specify categorical variables (also known as factors or CLASS variables) to be used in the analysis. Model effects, including covariates, main effects (CLASS variables), crossed effects (interactions), and nested effects, can be specified in the same way as in the GLM procedure. The CLASS statement supports the less-than-full-rank parameterization as in the GLM procedure as well as various full-rank parameterization methods such as reference coding, effect coding, and orthogonal polynomial coding. For some of the full-rank coding schemes, you can designate a specific value (category or level) of the CLASS variable as the reference level. The CLASS statement also enables you to specify the ordering of the categories of CLASS variables, to reverse the ordering of the categories, and to treat categories with missing values as valid categories.

With the TPHREG procedure, you can control how to move model effects in and out of a model with various model-building strategies such as forward selection, backward elimination, or stepwise selection. When there are no interaction terms, a main effect can enter or leave a model in a single step based on the $p$-value of the score or Wald statistic, respectively. When there are crossed or nested effects, the selection process also depends on whether you want to preserve model hierarchy. The HIERARCHY= option in the MODEL statement enables you to specify whether model hierarchy is to be preserved, how model hierarchy is applied, and whether a single effect or multiple effects can be moved in a single step.

The TPHREG procedure also enables you to specify CONTRAST statements for testing customized hypotheses concerning the regression parameters. Each CONTRAST statement also provides estimation of individual rows of contrasts, which is particularly useful in comparing the hazards between the categories of a CLASS variable.
Syntax

The PROC TPHREG statement invokes the TPHREG procedure. All the other statements in the PHREG procedure (with the exception of the experimental ASSESS statement) are available in the TPHREG procedure. The MODEL statement in the TPHREG procedure enables you to specify explanatory effects, not just individual continuous variables, and has additional options specifically for having CLASS variables. In addition, you can specify the CLASS statement and the CONTRAST statement as follows:

```plaintext
CLASS variable (options) <variable (options)> ...;
CONTRAST 'label' effect values <,... effect values>/ options;
```

The PROC TPHREG statement and the MODEL statement are required. The CLASS statement (if used) must precede the MODEL statement, and CONTRAST statements (if used) must follow the MODEL statement. The CLASS statement specifies the categorical variables to be used as explanatory variables. Variables specified in the CLASS statement have to exist in the input data. You cannot use programming statements to modify their values. The CONTRAST statement tests customized hypotheses concerning the regression parameters and estimates the parameters for the corresponding rows of contrasts.

PROC TPHREG Statement

```plaintext
PROC TPHREG < options > ;
```

All PROC PHREG statement options can be used in the PROC TPHREG statement. In addition, you can specify the following option:

```plaintext
NAMELEN=n
```

specifies the length of effect names in tables and output data sets to be \( n \) characters, where \( n \) is a value between 20 and 200. The default length is 20 characters.

MODEL Statement

```plaintext
MODEL time *censor ( list ) = effects < /options > ;
MODEL (t1, t2) *censor(list) = effects < /options > ;
```

The specifications of the time variables, the censoring indicator, and censored values are same as those in the PHREG procedure. The model `effects`, which follow the equal sign, include continuous or CLASS variables as the main effects. Categorical variables, which can be character or numeric, must be declared in the CLASS statement. Crossed and nested effects can be specified in the same fashion as in the GLM procedure (see the section “Specification of Effects” on page 1784 of Chapter 32, “The GLM Procedure,” for more information).
Any MODEL statement options in the PHREG procedure can be used in the TPHREG procedure. To accommodate the broader specification of model effects, the variable-selection options INCLUDE=, START=, and STOP= have been modified.

**INCLUDE=n**
includes the first \( n \) effects in the MODEL statement in every model. By default, INCLUDE=0. The INCLUDE= option has no effect when SELECTION=NONE.

**START=n**
begins the FORWARD, BACKWARD, or STEPWISE selection process with the first \( n \) effects listed in the MODEL statement. The value of \( n \) ranges from 0 to \( s \), where \( s \) is the total number of effects in the MODEL statement. The default value of \( n \) is \( s \) for the BACKWARD method and 0 for the FORWARD and STEPWISE methods. Note that START=\( n \) specifies only that the first \( n \) effects appear in the first model, while INCLUDE=\( n \) requires that the first \( n \) effects be included in every model. For the SCORE method, START=\( n \) specifies that the smallest models contain \( n \) effects, where \( n \) ranges from 1 to \( s \); the default value is 1. The START= option has no effect when SELECTION=NONE.

**STOP=n**
specifies the maximum (FORWARD method) or minimum (BACKWARD method) number of effects to be included in the final model. The effect selection process is stopped when \( n \) effects are found. The value of \( n \) ranges from 0 to \( s \), where \( s \) is the total number of effects in the MODEL statement. The default value of \( n \) is \( s \) for the FORWARD method and 0 for the BACKWARD method. For the SCORE method, STOP=\( n \) specifies that the smallest models contain \( n \) effects, where \( n \) ranges from 1 to \( s \); the default value of \( n \) is \( s \). The STOP= option has no effect when SELECTION=NONE or STEPWISE.

Two new options are added to the MODEL statement in the TPHREG procedure.

**HIERARCHY=keyword**

**HIER=keyword**
specifies whether and how the model hierarchy requirement is applied and whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only CLASS variable effects, or both CLASS and continuous variable effects, be subject to the hierarchy requirement. The HIERARCHY= option is ignored unless you also specify the FORWARD, BACKWARD, or STEPWISE selection method.

Model hierarchy refers to the requirement that, for any term to be in the model, all effects contained in the term must be present in the model. For example, in order for the interaction A*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor B can leave the model while the interaction A*B is in the model.
The keywords you can specify in the HIERARCHY= option are described as follows:

NONE

Model hierarchy is not maintained. Any single effect can enter or leave the model at any given step of the selection process.

SINGLE

Only one effect can enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that you specify the main effects A and B and the interaction of A*B in the model. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already been entered. Also, before A or B can be removed from the model, the A*B interaction must first be removed. All effects (CLASS and continuous variables) are subject to the hierarchy requirement.

SINGLECLASS

This is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

MULTIPLE

More than one effect can enter or leave the model at one time, subject to the model hierarchy requirement. In a forward selection step, a single main effect can enter the model, or an interaction can enter the model together with all the effects that are contained in the interaction. In a backward elimination step, an interaction itself, or the interaction together with all the effects that the interaction contains, can be removed. All effects (CLASS and continuous variable) are subject to the hierarchy requirement.

MULTIPLECLASS

This is the same as HIERARCHY=MULTIPLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=SINGLE, which means that model hierarchy is to be maintained for all effects (that is, both CLASS and continuous variable effects) and that only a single effect can enter or leave the model at each step.

NODUMMYPRINT
NODESIGNPRINT
NODP

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.
CLASS Statement

\texttt{CLASS \ variable <(options)> \ variable <(options)>...> < / options >;}

The CLASS statement names the categorical variables to be used in the analysis. The CLASS statement must precede the MODEL statement. You can specify various options for each variable by enclosing them in parentheses after the variable name. You can also specify global options for the CLASS statement by placing them after a slash (/). Global options are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the global options specified on any one CLASS statement apply to all CLASS statements. However, individual CLASS variable options override the global options.

\textbf{CPREFIX=} \textit{n}

specifies that, at most, the first \textit{n} characters of a CLASS variable name be used in creating names for the corresponding dummy variables. The default is $32 - \min(32, \max(2, f))$, where \textit{f} is the formatted length of the CLASS variable.

\textbf{DESCENDING}

\textbf{DESC}

reverses the sorting order of the categorical variable.

\textbf{LPREFIX=} \textit{n}

specifies that, at most, the first \textit{n} characters of a CLASS variable label be used in creating labels for the corresponding dummy variables.

\textbf{MISSING}

allows missing value (for example, '.' for a numeric variable and blanks for a character variable) as a valid value for the CLASS variable.

\textbf{ORDER=} \textbf{DATA | FORMATTED | FREQ | INTERNAL}

specifies the sorting order for the categories of categorical variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option may be useful when you use the CONTRAST statement. When the default ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. The following table shows how PROC TPHREG interprets values of the ORDER= option.

<table>
<thead>
<tr>
<th>Value of ORDER=</th>
<th>Levels Sorted By</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>order of appearance in the input data set</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value</td>
</tr>
<tr>
<td>FREQ</td>
<td>descending frequency count; levels with the most observations come first in the order</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>unformatted value</td>
</tr>
</tbody>
</table>
By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter on the SORT procedure in the SAS Procedures Guide and the discussion of BY-group processing in SAS Language Reference: Concepts.

PARAM=keyword

specifies the parameterization method for the categorical variable or variables. Design matrix columns are created from CLASS variables according to the following coding schemes. The default is PARAM=REF. If PARAM=ORTHPOLY or PARAM=POLY, and the CLASS levels are numeric, then the ORDER= option in the CLASS statement is ignored, and the internal, unformatted values are used. See the “CLASS Variable Parameterization” section on page 4482 for further details.

EFFECT specifies effect coding
GLM specifies less-than-full-rank, reference-cell coding; this option can only be used as a global option
ORDINAL specifies the cumulative parameterization for an ordinal CLASS variable.
POLYNOMIAL
POLY specifies polynomial coding
REFERENCE
REF specifies reference cell coding
ORTHEFFECT orthogonalizes PARAM=EFFECT
ORTHORDINAL orthogonalizes PARAM=ORDINAL
ORTHPOLY orthogonalizes PARAM=POLYNOMIAL
ORTHREF orthogonalizes PARAM=REFERENCE

The EFFECT, POLYNOMIAL, REFERENCE, ORDINAL, and their orthogonal parameterizations are full rank parameterization. The REF= option in the CLASS statement determines the reference level for the EFFECT, REFERENCE, and their orthogonal parameterizations.

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization.

REF='level' | keyword

specifies the reference level for PARAM=EFFECT or PARAM=REF. For an individual variable, you can specify a specific level of the variable in the REF= option. For a global or individual variable REF= option, you can use one of the following keywords. The default is REF=LAST.

FIRST designates the first ordered level as reference
LAST designates the last ordered level as reference
TRUNCATE

specifies that class levels should be determined using no more than the first 16 characters of the formatted values of CLASS variables. This is a global option, not an individual CLASS variable option.

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC GLM and PROC CATMOD, depending on the coding schemes used with any categorical variables involved.

The CONTRAST statement enables you to specify a matrix, \( L \), for testing the hypothesis \( L \beta = 0 \). You must be familiar with the details of the model parameterization that PROC TPHREG uses (for more information, see the PARAM= option in the “CLASS Statement” section on page 4477). Optionally, the CONTRAST statement enables you to estimate each row, \( l'_i \beta \), of \( L \beta \) and test the hypothesis \( l'_i \beta = 0 \). Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The following parameters are specified in the CONTRAST statement:

- **label** identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.
- **effect** identifies an effect that appears in the MODEL statement. You do not need to include all effects that are included in the MODEL statement.
- **values** are constants that are elements of the \( L \) matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of values to parameters.

The rows of \( L \) are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple row-descriptions. For any of the full-rank parameterizations, if an effect is not specified in the CONTRAST statement, all of its coefficients in the \( L \) matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.
When you use effect coding (by specifying PARAM=EFFECT in the CLASS statement), all parameters are directly estimable (involve no other parameters). For example, suppose an effect coded CLASS variable \( A \) has four levels. Then there are three parameters \((\alpha_1, \alpha_2, \alpha_3)\) representing the first three levels, and the fourth parameter is represented by

\[-\alpha_1 - \alpha_2 - \alpha_3\]

To test the first versus the fourth level of \( A \), you would test

\[\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3\]

or, equivalently,

\[2\alpha_1 + \alpha_2 + \alpha_3 = 0\]

which, in the form \( \mathbf{L}\beta = 0 \), is

\[
\begin{bmatrix}
2 & 1 & 1
\end{bmatrix}
\begin{bmatrix}
\alpha_1 \\
\alpha_2 \\
\alpha_3
\end{bmatrix} = 0
\]

Therefore, you would use the following CONTRAST statement:

\[
\text{contrast '1 vs. 4' A 2 1 1;}
\]

To contrast the third level with the average of the first two levels, you would test

\[\frac{\alpha_1 + \alpha_2}{2} = \alpha_3\]

or, equivalently,

\[\alpha_1 + \alpha_2 - 2\alpha_3 = 0\]

Therefore, you would use the following CONTRAST statement:

\[
\text{contrast '1&2 vs. 3' A 1 1 -2;}
\]

Other CONTRAST statements are constructed similarly. For example,

\[
\begin{align*}
\text{contrast '1 vs. 2 '} & \quad \text{A 1 -1 0;} \\
\text{contrast '1&2 vs. 4 '} & \quad \text{A 3 3 2;} \\
\text{contrast '1&2 vs. 3&4 '} & \quad \text{A 2 2 0;} \\
\text{contrast 'Main Effect'} & \quad \text{A 1 0 0,} \\
& \quad \text{A 0 1 0,} \\
& \quad \text{A 0 0 1;}
\end{align*}
\]
When you use the less-than-full-rank parameterization (by specifying PARAM=GLM in the CLASS statement), each row is checked for estimability. If PROC TPHREG finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. PROC TPHREG handles missing level combinations of categorical variables in the same manner as PROC GLM. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the \( L \) matrix in your CONTRAST statement. If the elements of \( L \) are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the GLM procedure does for its CONTRAST and ESTIMATE statements. For example, suppose that the model contains effects A and B and their interaction A*B. If you specify a CONTRAST statement involving A alone, the \( L \) matrix contains nonzero terms for both A and A*B, since A*B contains A.

The degrees of freedom is the number of linearly independent constraints implied by the CONTRAST statement, that is, the rank of \( L \).

You can specify the following options after a slash (/).

**ALPHA=** \( p \)

specifies the level of significance \( p \) for the \( 100(1 - p)\% \) confidence interval for each contrast when the ESTIMATE option is specified. The value \( p \) must be between 0 and 1. By default, \( p \) is equal to the value of the ALPHA= option in the PROC TPHREG statement, or 0.05 if that option is not specified.

**E**

requests that the \( L \) matrix be displayed.

**ESTIMATE=** *keyword*

requests that each individual contrast (that is, each row, \( l_i' \beta \), of \( L\beta \)) or exponentiated contrast \( (e^{l_i'\beta}) \) be estimated and tested. PROC TPHREG displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast \( (e^{l_i'\beta}) \), or both, by specifying one of the following *keywords*:

- **PARM** specifies that the contrast itself be estimated
- **EXP** specifies that the exponentiated contrast be estimated
- **BOTH** specifies that both the contrast and the exponentiated contrast be estimated

**SINGULAR =** \( \text{number} \)

 tunes the estimability check. This option is ignored when the full-rank parameterization is used. If \( v \) is a vector, define \( \text{ABS}(v) \) to be the largest absolute value of the elements of \( v \). For a row vector \( l' \) of the contrast matrix \( L \), define \( c \) to be equal to \( \text{ABS}(l) \) if \( \text{ABS}(l) \) is greater than 0; otherwise, \( c \) equals 1. If \( \text{ABS}(l' - l'T) \) is greater than \( c \times \text{number} \), then \( l \) is declared nonestimable. The \( T \) matrix is the Hermite form matrix \( I_0^{-1} I_0 \), where \( I_0^{-1} \) represents a generalized inverse of the information matrix \( I_0 \).
of the null model. The value for `number` must be between 0 and 1; the default value is $1E^{-4}$.

## Details

### CLASS Variable Parameterization

Consider a model with one CLASS variable `A` with four levels, 1, 2, 5, and 7. Details of the possible choices for the `PARAM=` option follow.

**EFFECT**

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of $-1$. For instance, if the reference level is 7 (REF=7), the design matrix columns for `A` are as follows.

<table>
<thead>
<tr>
<th>Design Matrix</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A1</td>
</tr>
<tr>
<td></td>
<td>A2</td>
</tr>
<tr>
<td></td>
<td>A5</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>$-1$</td>
</tr>
</tbody>
</table>

Parameter estimates of CLASS main effects using the effect coding scheme estimate the difference in the effect of each nonreference level compared to the average effect over all four levels.

**GLM**

As in PROC GLM, four columns are created to indicate group membership. The design matrix columns for `A` are as follows.

<table>
<thead>
<tr>
<th>Design Matrix</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A1</td>
</tr>
<tr>
<td></td>
<td>A2</td>
</tr>
<tr>
<td></td>
<td>A5</td>
</tr>
<tr>
<td></td>
<td>A7</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
</tr>
</tbody>
</table>

Parameter estimates of CLASS main effects using the GLM coding scheme estimate the difference in the effects of each level compared to the last level.
ORDINAL  Three columns are created to indicate group membership of the higher levels of the effect. For the first level of the effect (which for A is 1), all three dummy variables have a value of 0. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Ordinal Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A2 A5 A7</td>
</tr>
<tr>
<td>1</td>
<td>0 0 0</td>
</tr>
<tr>
<td>2</td>
<td>1 0 0</td>
</tr>
<tr>
<td>5</td>
<td>1 1 0</td>
</tr>
<tr>
<td>7</td>
<td>1 1 1</td>
</tr>
</tbody>
</table>

The first level of the effect is a control or baseline level. Parameter estimates of CLASS main effects using the ORDINAL coding scheme estimate the effect on the response as the ordinal factor is set to each succeeding level. When the parameters for an ordinal main effect have the same sign, the response effect is monotonic across the levels.

POLYNOMIAL

POLY  Three columns are created. The first represents the linear term \(x\), the second represents the quadratic term \(x^2\), and the third represents the cubic term \(x^3\), where \(x\) is the level value. If the CLASS levels are not numeric, they are translated into 1, 2, 3, \ldots according to their sorting order. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Polynomial Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>APOLY1 APOLY2 APOLY3</td>
</tr>
<tr>
<td>1</td>
<td>1 1 1</td>
</tr>
<tr>
<td>2</td>
<td>2 4 8</td>
</tr>
<tr>
<td>5</td>
<td>5 25 125</td>
</tr>
<tr>
<td>7</td>
<td>7 49 343</td>
</tr>
</tbody>
</table>
REFERENCE

REF

Three columns are created to indicate group membership of the nonreference levels. For the reference level, all three dummy variables have a value of 0. For instance, if the reference level is 7 (REF=7), the design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Reference Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
</table>
| A
| A1 | A2 | A5 |
| 1  | 1  | 0  | 0  |
| 2  | 0  | 1  | 0  |
| 5  | 0  | 0  | 1  |
| 7  | 0  | 0  | 0  |

Parameter estimates of CLASS main effects using the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

ORTHEFFECT

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=EFFECT. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Orthogonal Effect Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
</table>
| A
| AOEFF1 | AOEFF2 | AOEFF3 |
| 1  | 1.41421 | -0.81650 | -0.57735 |
| 2  | 0.00000 | 1.63299  | -0.57735 |
| 5  | 0.00000 | 0.00000  | 1.73205  |
| 7  | -1.41421| -0.81649 | -0.57735 |

ORTHORDINAL

The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=ORDINAL. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Orthogonal Ordinal Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
</table>
| A
| AOORD1 | AOORD2 | AOORD3 |
| 1  | -1.73205| 0.00000 | 0.00000 |
| 2  | 0.57735 | -1.63299| 0.00000 |
| 5  | 0.57735 | 0.81650 | -1.41421 |
| 7  | 0.57735 | 0.81650 | 1.41421 |
ORTHPOLY The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=POLY. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Orthogonal Polynomial Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>AOPOLY1</td>
</tr>
<tr>
<td>1</td>
<td>-1.153</td>
</tr>
<tr>
<td>2</td>
<td>-0.734</td>
</tr>
<tr>
<td>5</td>
<td>0.524</td>
</tr>
<tr>
<td>7</td>
<td>1.363</td>
</tr>
</tbody>
</table>

ORTHREF The columns are obtained by applying the Gram-Schmidt orthogonalization to the columns for PARAM=REFERENCE. The design matrix columns for A are as follows.

<table>
<thead>
<tr>
<th>Orthogonal Reference Coding</th>
<th>Design Matrix</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>AOREF1</td>
</tr>
<tr>
<td>1</td>
<td>1.73205</td>
</tr>
<tr>
<td>2</td>
<td>-0.57735</td>
</tr>
<tr>
<td>5</td>
<td>-0.57735</td>
</tr>
<tr>
<td>7</td>
<td>-0.57735</td>
</tr>
</tbody>
</table>

Miscellaneous Changes from PROC PHREG

The default method of computing the survivor function estimate is METHOD=CH which is based on the empirical cumulative hazard function estimate rather than the product-limit estimate (METHOD=PL) as in PROC PHREG. This applies to both the OUTPUT and BASELINE statements.

The OUT= data set in the OUTPUT statement contains the entire input data set along with statistics you request using the keyword=name options. Observations in the OUT= data set follow the same order as the input data set. The ORDER=SORTED option in the OUTPUT statement of PROC PHREG (see the “OUTPUT Statement” section (page 3233) in Chapter 54, “The PHREG Procedure,”) is no longer available.

The BASELINE statement in PROC PHREG enables you to to predict the cumulative mean function (CMF) and the cumulative hazard function (CUMHAZ) for recurrent events models. However, such features are not yet available in the BASELINE statement of PROC TPHREG.
Displayed Output

If you use the NOPRINT option in the PROC TPHREG statement, the procedure does not display any output. Otherwise, the displayed output of the TPHREG procedure includes the following:

- the “Model Information” table, which contains
  - the two-level name of the input data set
  - the name and label of the failure-time variable
  - if you specify the censoring variable,
    - the name and label of the censoring variable
    - the values that the censoring variable assumes to indicate censored times
  - if you use the OFFSET= option in the MODEL statement, the name and label of the offset variable
  - if you specify the FREQ statement, the name and label of the frequency variable
  - if you specify the WEIGHT statement, the name and label of the weight variable
  - the method of handling ties in the failure time
- the “Class Level Information” table, which shows the levels and the corresponding design variables for each CLASS explanatory variable
- the “Summary of the Number of Event and Censored Values” table, which gives, for each stratum, the breakdown of the number of events and censored values. This table is not produced if the NOSUMMARY option is specified.
- if you specify the SIMPLE option in the PROC TPHREG statement, the “Descriptive Statistics for Continuous Explanatory Variables” table for continuous explanatory variables, and the “Frequency Distribution of CLASS Variables” table. The “Descriptive Statistics for Continuous Explanatory Variables” table contains the mean, standard deviation, maximum and minimum of each continuous variable specified in the MODEL statement. If the WEIGHT statement is specified, the “Frequency Distribution of Class Variables” table also contains the weight distributions of the CLASS variables.
- if you specify the ITPRINT option in the MODEL statement, the “Iteration History” table, which displays the iteration number, step size, log likelihood, and parameter estimates at each iteration The last evaluation of the gradient vector is also displayed.
- the “Model Fit Statistics” table, which gives the values of $-2 \log$ likelihood for fitting a model with no explanatory variable and for fitting a model with all the explanatory variables. The AIC and SBC are also given in this table.
- the “Testing Global Null Hypothesis: BETA=0” table, which displays results of the likelihood ratio test, the score test, and the Wald test.
• if the model contains an effect involving a CLASS variable, the “Type 3 Tests” table, which gives the Wald chi-square statistic, the degrees of freedom, and the \( p \)-value for each effect in the model

• the “Analysis of Maximum Likelihood Estimates” table, which contains the following:
  
  – the maximum likelihood estimate of the parameter
  – the estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
  – if you specify the COVS option in the PROC statement, the ratio of the robust standard error estimate to the model-based standard error estimate
  – the Wald Chi-Square statistic, computed as the square of the parameter estimate divided by its standard error estimate
  – the degrees of freedom of the Wald chi-square statistic. It has a value of 1 unless the corresponding parameter is redundant or infinite, in which case the value is 0.
  – the \( p \)-value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
  – the hazards ratio estimate computed by exponentiating the parameter estimate
  – if you specified the RISK Limits option in the MODEL statement, the confidence limits for the hazards ratio

• if you specify SELECTION=SCORE in the MODEL statement, the “Regression Models Selected by Score Criterion” table, which gives the number of explanatory variables in each model, the score chi-square statistic, and the names of the variables included in the model

• if you use the FORWARD or STEPWISE selection method and specify the DETAILS option in the MODEL statement, the “Effects to Enter” table, which gives the score chi-square statistic for testing the significance of each candidate effect for entry (after adjusting for the effects already in the model), the degrees of freedom of the score chi-square statistic, and the corresponding \( p \)-value. This table is produced before an effect is selected for entry.

• if you use the BACKWARD or STEPWISE selection method and specify the DETAILS option in the MODEL statement, the “Effects to Remove” table, which gives the Wald chi-square statistic for testing the significance of each candidate effect for removal, the degrees of freedom of the Wald chi-square, and the corresponding \( p \)-value. This table is produced before an effect is selected for removal.

• if you use the BACKWARD, FORWARD, or STEPWISE selection method, a table summarizing the model-building process, which gives the step number, the effect entered or removed at each step, the chi-square statistic, and the corresponding \( p \)-value on which the selection is based

• if you use the COVB option in the MODEL statement, the estimated covariance matrix of the parameter estimates
• if you use the CORRB option in the MODEL statement, the estimated correlation matrix of the parameter estimates

• if you specify a CONTRAST statement, the “Contrast Test Results” table, which gives the result of the Wald test for each CONTRAST specified. If you specify the E option in the CONTRAST statement, then the contrast matrix is displayed. If you specify the ESTIMATE= option in the CONTRAST statement, the “Contrast Rows Estimation and Testing Results” table is produced, which includes the point estimate and confidence interval for each row of the contrast matrix, and the corresponding Wald test as well.

• if you specify a TEST statement,
  – the “Linear Coefficients” table, which gives the coefficients and constants of the linear hypothesis (if the E option is specified)
  – the printing of the intermediate calculations of the Wald test (if the option PRINT is specified)
  – the “Test Results” table, which gives the Wald chi-square statistic, the degrees of freedom, and the $p$-value
  – the “Average Effect” table, which gives the weighted average of the parameter estimates for the variables in the TEST statement, the estimated standard error, the z-score, and the $p$-value (if the AVERAGE option is specified)

**ODS Table Names**

PROC TPHREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

**Table 73.1.** ODS Tables Produced in PROC TPHREG

<table>

Example 73.1. Analysis of the VA Lung Cancer Data

This example uses the Veteran’s Administration lung cancer data presented in Appendix 1 of Kalbfleisch and Prentice (1980). In this trial, males with advanced inoperable lung cancer were randomized to a standard therapy and a test chemotherapy. The primary end point for the therapy comparison was time to death in days, represented by the variable Time. Negative values of Time are censored values. The data include information on a number of explanatory variables: Therapy (type of therapy: standard or test), Cell (type of tumor cell: adenocarcinoma, large, small, or squamous), Prior (prior therapy: 0=no, 10=yes), Age (age in years), Duration (months from diagnosis to randomization), and Kps (Karnofsky performance scale). A censoring indicator variable Censor is created from the data, with value 1 indicating a censored time and value 0 an event time.

Example 73.1. Analysis of the VA Lung Cancer Data

PROC TPHREG is invoked to fit the Cox proportional hazards model to these data. Variables Prior, Cell, and Therapy, which are categorical variables, are declared in the CLASS statement. By default, PROC TPHREG parameterizes the CLASS variables using the reference coding with the last category as the reference category. However, you can explicitly specify the reference category of your choice. Here, Prior=no is chosen as the reference category for prior therapy, Cell=large is chosen as the reference category for type of tumor cell, and Therapy=standard is chosen as the reference category for the type of therapy. Both the continuous explanatory variables (Kps, Duration, and Age) and the CLASS explanatory variables (Prior, Cell, and Therapy) are specified in the MODEL statement. Knowing how the Cell variable is parameterized, the hazards ratios of all pairs of cell-type groups can be estimated using the ESTIMATE=EXP option in a CONTRAST statement.

```plaintext
proc tphreg data=VALung;
  class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
  model Time*censor(1) = Kps Duration Age Prior Cell Therapy;
  contrast 'Pairwise' cell 1 0 0, /* adeno vs large */
   cell 0 1 0, /* small vs large */
   cell 0 0 1, /* squamous vs large */
   cell 1 -1 0, /* adeno vs small */
   cell 1 0 -1, /* adeno vs squamous */
   cell 0 1 -1 /* small vs squamous */
   / estimate=exp;
run;
```

The output of PROC TPHREG is very similar to that of PROC PHREG, with additional tables for displaying the parameterization of the CLASS variables, the multiparameter tests for the model effects, and the analysis results of the specified contrasts.
Output 73.1.1. Reference Coding of CLASS Variables

<table>
<thead>
<tr>
<th>Class</th>
<th>Value</th>
<th>Design Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prior</td>
<td>no</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>yes</td>
<td>1</td>
</tr>
<tr>
<td>Cell</td>

<tr>
<td></td>
<td>small</td>
<td>0 1 0</td>
</tr>
<tr>
<td></td>
<td>squamous</td>
<td>0 0 1</td>
</tr>
<tr>
<td>Therapy</td>
<td>standard</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>test</td>
<td>1</td>
</tr>
</tbody>
</table>

Coding of the CLASS variables is displayed in Output 73.1.1. There is one dummy variable for Prior and one for Therapy, since both variables are binary. The dummy variable has a value of 0 for the reference category (Prior=no, Therapy=standard). The CLASS variable Cell has four categories and are represented by three dummy variables. Note that the reference category, Cell=large, has a value of 0 for all three dummy variables.

Output 73.1.2. Wald Tests for Individual Model Effects

<table>
<thead>
<tr>
<th>Effect</th>
<th>DF</th>
<th>Wald Chi-Square</th>
<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kps</td>
<td>1</td>
<td>35.1124</td>
<td>&lt;.0001</td>
</tr>
<tr>
<td>Duration</td>
<td>1</td>
<td>0.0001</td>
<td>0.9920</td>
</tr>
<tr>
<td>Age</td>
<td>1</td>
<td>0.8443</td>
<td>0.3582</td>
</tr>
<tr>
<td>Prior</td>
<td>1</td>
<td>0.0971</td>
<td>0.7554</td>
</tr>
<tr>
<td>Cell</td>
<td>3</td>
<td>17.9164</td>
<td>0.0005</td>
</tr>
<tr>
<td>Therapy</td>
<td>1</td>
<td>1.9579</td>
<td>0.1617</td>
</tr>
</tbody>
</table>

The test results of individual model effects are shown in Output 73.1.2. There is a strong prognostic effect of the Karnofsky performance status on patient survival ($p < 0.0001$), and the survival times in the various cell-type groups differ significantly ($p = 0.0005$). However, there is a lack of evidence that the test chemotherapy differs from the standard therapy ($p = 0.1617$) after accounting for the prognostic effects of other variables.
### Output 73.1.3. Inference about the Regression Parameters

</tbody>
</table>

In the Cox proportional hazards model, the effects of the covariates are to act multiplicatively on the hazard of the survival time, and therefore it is a little easier to interpret the corresponding hazards ratios than the regression parameters. For a parameter that corresponds to a continuous variable, the hazard ratio is the ratio of hazard rates for an increase of one unit of the variable. From Output 73.1.3, the hazard ratio estimate for Kps is 0.968, meaning that an increase of 10 units in Karnofsky performance scale will shrink the hazard rate by $1 - (0.968)^{10}=28\%$. For a CLASS variable parameter, the hazard ratio is the ratio of the hazard rates between the given category and the reference category. The hazard rate of Cell=adenocarcinoma is 220\% that of Cell=large, the hazard rate of Cell=small is 158\% that of Cell=large, and the hazard rate of Cell=squamous is only 67\% that of Cell=large.

### Output 73.1.4. Overall Test for All Paired Cell-type Groups

</tr>
</tbody>
</table>

Output 73.1.5 is generated by the ESTIMATE=EXP option in the CONTRAST statement. Values of the Estimate column are the estimated hazard ratios: 2.200 for ‘adeno’ vs ‘large’, 1.579 for ‘small’ versus ‘large’, 0.671 for ‘squamous’ versus ‘large’, 1.394 for ‘adeno’ versus ‘small’, 3.282 for ‘adeno’ versus ‘squamous’, and 2.355 for ‘small’ versus ‘squamous’. Note that the first three hazard ratio estimates are already given in the parameter estimate table (Output 73.1.3), and therefore there is no need to specify those first three rows in the CONTRAST statement.

</table>
The TPSPLINE procedure uses the penalized least squares method to fit a nonparame-
metric regression model. It computes thin-plate smoothing splines to approximate
smooth multivariate functions observed with noise. The TPSPLINE procedure al-
low great flexibility in the possible form of the regression surface. In particular,
PROC TPSPLINE makes no assumptions of a parametric form for the model. The
generalized cross validation (GCV) function may be used to select the amount of
smoothing.

The TPSPLINE procedure complements the methods provided by the standard SAS
regression procedures such as the GLM, REG and NLIN procedures. These proce-
dures can handle most situations in which you specify the regression model and the
model is known up to a fixed number of parameters. However, when you have no
prior knowledge about the model, or when you know that the data cannot be repre-
sented by a model with a fixed number of parameters, you can use the TPSPLINE
procedure to model the data.

The TPSPLINE procedure uses the penalized least squares method to fit the data with
a flexible model in which the number of effective parameters can be as large as the
number of unique design points. Hence, as the sample size increases, the model space
increases as well, enabling the thin-plate smoothing spline to fit more complicated
situations.

The main features of the TPSPLINE procedure are as follows:

- provides penalized least squares estimates
- supports the use of multidimensional data
- supports multiple SCORE statements
- fits both semiparametric models and nonparametric models
- provides options for handling large data sets
- supports multiple dependent variables
- enables you to choose a particular model by specifying the model degrees of
  freedom or smoothing parameter

The Penalized Least Squares Estimate

Penalized least squares estimates provide a way to balance fitting the data closely and
avoiding excessive roughness or rapid variation. A penalized least squares estimate
is a surface that minimizes the penalized least squares over the class of all surfaces satisfying sufficient regularity conditions.

Define \( x_i \) as a \( d \)-dimensional covariate vector, \( z_i \) as a \( p \)-dimensional covariate vector, and \( y_i \) as the observation associated with \((x_i, z_i)\). Assuming that the relation between \( z_i \) and \( y_i \) is linear but the relation between \( x_i \) and \( y_i \) is unknown, you can fit the data using a semiparametric model as follows:

\[
y_i = f(x_i) + z_i \beta + \epsilon_i
\]

where \( f \) is an unknown function that is assumed to be reasonably smooth, \( \epsilon_i, i = 1, \cdots, n \) are independent, zero-mean random errors, and \( \beta \) is a \( p \)-dimensional unknown parametric vector.

This model consists of two parts. The \( z_i \beta \) is the parametric part of the model, and the \( z_i \) are the regression variables. The \( f(x_i) \) is the nonparametric part of the model, and the \( x_i \) are the smoothing variables.

The ordinary least squares method estimates \( f(x_i) \) and \( \beta \) by minimizing the quantity:

\[
\frac{1}{n} \sum_{i=1}^{n} (y_i - f(x_i) - z_i \beta)^2
\]

However, the functional space of \( f(x) \) is so large that you can always find a function \( f \) that interpolates the data points. In order to obtain an estimate that fits the data well and has some degree of smoothness, you can use the penalized least squares method.

The penalized least squares function is defined as

\[
S_\lambda(f) = \frac{1}{n} \sum_{i=1}^{n} (y_i - f(x_i) - z_i \beta)^2 + \lambda J_2(f)
\]

where \( J_2(f) \) is the penalty on the roughness of \( f \) and is defined, in most cases, as the integral of the square of the second derivative of \( f \).

The first term measures the goodness of fit and the second term measures the smoothness associated with \( f \). The \( \lambda \) term is the smoothing parameter, which governs the tradeoff between smoothness and goodness of fit. When \( \lambda \) is large, it more heavily penalizes rougher fits. Conversely, a small value of \( \lambda \) puts more emphasis on the goodness of fit.

The estimate \( f_\lambda \) is selected from a reproducing kernel Hilbert space, and it can be represented as a linear combination of a sequence of basis functions. Hence, the final estimates of \( f \) can be written as

\[
f_\lambda(x_i) = \theta_0 + \sum_{j=1}^{d} \theta_j x_{ij} + \sum_{j=1}^{n} \delta_j B_j(x_i)
\]
where $B_j$ is the basis function, which depends on where the data $x_j$ is located, and $\theta_j$ and $\delta_j$ are the coefficients that need to be estimated.

For a fixed $\lambda$, the coefficients $(\theta, \delta, \beta)$ can be estimated by solving an $n \times n$ system. The smoothing parameter can be chosen by minimizing the generalized cross validation (GCV) function.

If you write

$$\hat{y} = A(\lambda)y$$

then $A(\lambda)$ is referred to as the hat or smoothing matrix, and the GCV function $V(\lambda)$ is defined as

$$V(\lambda) = \frac{(1/n)||I - A(\lambda)||^2}{(1/n)\text{tr}(I - A(\lambda))^2}$$

### PROC TPSPLINE with Large Data Sets

The calculation of the penalized least squares estimate is computationally intensive. The amount of memory and CPU time needed for the analysis depend on the number of unique design points, which corresponds to the number of unknown parameters to be estimated.

You can specify the D=value option in the MODEL statement to reduce the number of unknown parameters. The option groups design points by the specified range (see the D= option on page 4509).

PROC TPSPLINE selects one design point from the group and treats all observations in the group as replicates of that design point. Calculation of the thin-plate smoothing spline estimates are based on the reprocessed data. The way to choose the design point from a group depends on the order of the data. Therefore, different orders of input data may result in different estimates.

This option, by combining several design points into one, reduces the number of unique design points, thereby approximating the original data. The D= value you specify determines the width of the range used to group the data.

### Getting Started

The following example demonstrates how you can use the TPSPLINE procedure to fit a semiparametric model.

Suppose that $y$ is a continuous variable and $x1$ and $x2$ are two explanatory variables of interest. To fit a smoothing spline model, you can use a MODEL statement similar to that used in many regression procedures in the SAS System.

```sas
proc tpspline;
  model y = (x1 x2);
run;
```
The TPSPLINE procedure can fit semiparametric models; the parentheses in the preceding MODEL statement separates the smoothing variables from the regression variables. The following statements illustrates this syntax.

```plaintext
proc tpspline;
  model y = x3 (x1 x2);
run;
```

This model assumes a linear relation with $x_3$ and an unknown functional relation with $x_1$ and $x_2$.

If you want to fit several responses using the same explanatory variables, you can save computation time by using the multiple responses feature in the MODEL statement. For example, if $y_1$ and $y_2$ are two response variables, the following MODEL statement can be used to fit two models. Separate analyses are then performed for each response variable.

```plaintext
proc tpspline;
  model y1 y2 = (x1 x2);
run;
```

The following example illustrates the use of PROC TPSPLINE. The data are from Bates, Lindstrom, Wahba, and Yandell (1987).

;
```
The data set Measure contains three variables $x_1$, $x_2$, and $y$. Suppose that you want to fit a surface by using the variables $x_1$ and $x_2$ to model the response $y$. The variables $x_1$ and $x_2$ are spaced evenly on a $[-1 \times 1] \times [-1 \times 1]$ square, and the response $y$ is generated by adding a random error to a function $f(x_1, x_2)$. The raw data are plotted using the G3D procedure. In order to plot those replicates, the data are jittered a little bit.

```
data Measure1;
  set Measure;
run;

proc sort data=Measure1;
  by x2 x1;
run;

data measure1;
  set measure1; by x1;
  if last.x1 then x1=x1+0.00001;
run;

proc g3d data=Measure1;
  scatter x2*x1=y /size=.5
      zmin=9 zmax=21
      zticknum=4;
  title "Raw Data";
run;
```

Figure 74.1 displays the raw data.

Figure 74.1. Plot of Data Set MEASURE
The following statements invoke the TPSPLINE procedure, using the Measure data set as input. In the MODEL statement, the x1 and x2 variables are listed as smoothing variables. The LOGNLAMBDA= option returns a list of GCV values with \( \log_{10}(n\lambda) \) ranging from \(-4\) to \(-2\). The OUTPUT statement creates the data set estimate to contain the predicted values and the 95% upper and lower confidence limits.

```plaintext
proc tpspline data=Measure;
  model y=(x1 x2) /lognlambda=(-4 to -2 by 0.1);
  output out=estimate pred uclm lclm;
run;

proc print data=estimate;
run;
```

The results of this analysis are displayed in the following figures. Figure 74.2 shows that the data set Measure contains 50 observations with 25 unique design points. The GCV values are listed along with the \( \log_{10}(n\lambda) \). The value of \( \log_{10}(n\lambda) \) that minimizes the GCV function is around \(-3.5\). The final thin-plate smoothing spline estimate is based on LOGNLAMBDA = \(-3.4762\). The residual sum of squares is 0.246110, and the degrees of freedom is 24.593203. The standard deviation, defined as \( \text{RSS}/(\text{Tr}(I-A)) \), is 0.098421. The predictions and 95% confidence limits are displayed in Figure 74.3.

**Figure 74.3.** Data Set ESTIMATE

The fitted surface is plotted with PROC G3D as follows.

```plaintext
proc g3d data=estimate;
plot x2*x1=p_y/grid
    zmin=9 zmax=21 zticknum=4;
    title 'Plot of Fitted Surface';
run;
```
The resulting plot is displayed in Figure 74.4.

![Plot of Fitted Surface](image)

**Figure 74.4.** Plot of TPSPLINE Fit of Data Set Measure

Because the data in data set Measure are very sparse, the fitted surface is not smooth. To produce a smoother surface, the following statements generate the data set Pred in order to obtain a finer grid. The SCORE statement evaluates the fitted surface at those new design points.

```sas
data pred;
  do x1=-1 to 1 by 0.1;
    do x2=-1 to 1 by 0.1;
      output;
    end;
  end;
run;

proc tpspline data=measure;
  model y=(x1 x2)/lognlambda=(-4 to -2 by 0.1);
  score data=pred out=predy;
run;

proc g3d data=predy;
  plot x2*x1=p_y/grid
    zmin=9 zmax=21 zticknum=4;
  title 'Plot of Fitted Surface on a Fine Grid';
run;
```

The surface plot based on the finer grid is displayed in Figure 74.5. The plot shows
that a parametric model with quadratic terms of $x_1$ and $x_2$ provides a reasonable fit to the data.

![Plot of Fitted Surface on a Fine Grid](image)

**Figure 74.5.** Plot of TPSPLINE fit

### Syntax

```
PROC TPSPLINE < option >;
   MODEL dependents = < variables > (variables) < /options >;
   SCORE data=SAS-data-set out=SAS-data-set ;
   OUTPUT < out=SAS-data-set > keyword < · · · keyword > ;
   BY variables ;
   FREQ variable ;
   ID variables ;
```

The syntax in PROC TPSPLINE is similar to that of other regression procedures in the SAS System. The PROC TPSPLINE and MODEL statements are required. The SCORE statement can appear multiple times; all other statements appear only once.

The syntax for PROC TPSPLINE is described in the following sections in alphabetical order after the description of the PROC TPSPLINE statement.
The PROC TPSPLINE statement invokes the procedure. You can specify the following option.

DATA=SAS-data-set  
specifies the SAS data set to be read by PROC TPSPLINE. The default value is the most recently created data set.

You can specify a BY statement with PROC TPSPLINE to obtain separate analysis on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TPSPLINE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

If one variable in your input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC TPSPLINE treats the data as if each observation appears \( n \) times, where \( n \) is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than one, the observation is not used in the analysis. Only the integer portion of the value is used.
ID Statement

ID variables;

The variables in the ID statement are copied from the input data set to the OUT= data set. If you omit the ID statement, only the variables used in the MODEL statement and requested statistics are included in the output data set.

MODEL Statement

MODEL dependents = < regression variables > (smoothing variables) < /options > ;

The MODEL statement specifies the dependent variables, the independent regression variables, which are listed with no parentheses, and the independent smoothing variables, which are listed inside parentheses.

The regression variables are optional. At least one smoothing variable is required, and it must be listed after the regression variables. No variables can be listed in both the regression variable list and the smoothing variable list.

If you specify more than one dependent variable, PROC TPSPLINE calculates a thin-plate smoothing spline estimate for each dependent variable, using the regression variables and smoothing variables specified on the right-hand side.

If you specify regression variables, PROC TPSPLINE fits a semiparametric model using the regression variables as the linear part of the model.

You can specify the following options in the MODEL statement.

ALPHA=number

specifies the significance level $\alpha$ of the confidence limits on the final thin-plate smoothing spline estimate when you request confidence limits to be included in the output data set. Specify number as a value between 0 and 1. The default value is 0.05. See the “OUTPUT Statement” section on page 4510 for more information on the OUTPUT statement.

DF=number

specifies the degrees of freedom of the thin-plate smoothing spline estimate, defined as

$$df = \text{trace}(A(\lambda))$$

where $A(\lambda)$ is the hat matrix. Specify number as a value between zero and the number of unique design points.
MODEL Statement

DISTANCE=number

D=number

defines a range such that if two data points \((x_i, z_i)\) and \((x_j, z_j)\) satisfy

\[ \max_k |x_{ik} - x_{jk}| \leq D/2 \]

then these data points are treated as replicates, where \(x_i\) are the smoothing variables and \(z_i\) are the regression variables.

You can use the DISTANCE= option to reduce the number of unique design points by treating nearby data as replicates. This can be useful when you have a large data set. The default value is 0.

LAMBDA0=number

specifies the smoothing parameter, \(\lambda_0\), to be used in the thin-plate smoothing spline estimate. By default, PROC TPSPLINE uses the \(\lambda\) parameter that minimizes the GCV function for the final fit. The LAMBDA0= value must be positive.

LAMBDA=list-of-values

specifies a set of values for the \(\lambda\) parameter. PROC TPSPLINE returns a GCV value for each \(\lambda\) point that you specify. You can use the LAMBDA= option to study the GCV function curve for a set of values for \(\lambda\). All values listed in the LAMBDA= option must be positive.

LOGNLAMBDA0=number

LOGNL0=number

specifies the smoothing parameter \(\lambda_0\) on the \(\log_{10}(n\lambda)\) scale. If you specify both the LOGNL0= and LAMBDA0= options, only the value provided by the LOGNL0= option is used. By default, PROC TPSPLINE uses the \(\lambda\) parameter that minimizes the GCV function for the estimate.

LOGNLAMBDA=list-of-values

LOGNL=list-of-values

specifies a set of values for the \(\lambda\) parameter on the \(\log_{10}(n\lambda)\) scale. PROC TPSPLINE returns a GCV value for each \(\lambda\) point that you specify. You can use the LOGNLAMBDA= option to study the GCV function curve for a set of \(\lambda\) values. If you specify both the LOGNL= and LAMBDA= options, only the list of values provided by LOGNL= option is used.

In some cases, the LOGNL= option may be preferred over the LAMBDA= option. Because the LAMBDA= value must be positive, a small change in that value can result in a major change in the GCV value. If you instead specify \(\lambda\) on the \(\log_{10}\) scale, the allowable range is enlarged to include negative values. Thus, the GCV function is less sensitive to changes in LOGNLAMBDA.

M=number

specifies the order of the derivative in the penalty term. The M= value must be a positive integer. The default value is the \(\max(2, INT(d/2) + 1)\), where \(d\) is the number of smoothing variables.
**SCORE Statement**

```sas
SCORE DATA=SAS-data-set OUT=SAS-data-set ;
```

The SCORE statement calculates predicted values for a new data set. If you have multiple data sets to predict, you can specify multiple SCORE statements. You must use a SCORE statement for each data set.

The following keywords must be specified in the SCORE statement.

**DATA=SAS-data-set**

specifies the input SAS data set containing the smoothing variables \( x \) and regression variables \( z \). The predicted response (\( y \)) value is computed for each \((x, z)\) pair. The data set must include all independent variables specified in the MODEL statement.

**OUT=SAS-data-set**

specifies the name of the SAS data set to contain the predictions.

**OUTPUT Statement**

```sas
OUTPUT OUT=SAS-data-set < keyword · · · keyword > ;
```

The OUTPUT statement creates a new SAS data set containing diagnostic measures calculated after fitting the model.

You can request a variety of diagnostic measures that are calculated for each observation in the data set. The new data set contains the variables specified in the MODEL statement in addition to the requested variables. If no `keyword` is present, the data set contains only the predicted values.

Details on the specifications in the OUTPUT statement are as follows.

**OUT=SAS-data-set**

specifies the name of the new data set to contain the diagnostic measures. This specification is required.

**keyword**

specifies the statistics to include in the output data set. The names of the new variables that contain the statistics are formed by using a prefix of one or more characters that identify the statistic, followed by an underscore (\_), followed by the dependent variable name.

For example, suppose that you have two dependent variables, say \( y_1 \) and \( y_2 \), and you specify the keywords PRED, ADIAG, and UCLM. The output SAS data set will contain the following variables:
The theoretical foundations for the thin-plate smoothing spline are described in Duchon (1976, 1977) and Meinguet (1979). Further results and applications are given in Wahba and Wendelberger (1980), Hutchinson and Bischof (1983), and Seaman and Hutchinson (1985).

Suppose that \( \mathcal{H}_m \) is a space of functions whose partial derivatives of total order \( m \) are in \( L_2(E^d) \) where \( E^d \) is the domain of \( x \).

Now, consider the data model

\[
y_i = f(x_1(i), \ldots, x_d(i)) + \epsilon_i, \quad i = 1, \ldots, n
\]

where \( f \in \mathcal{H}_m \).

Using the notation from the section “The Penalized Least Squares Estimate” on page 4497, for a fixed \( \lambda \), estimate \( f \) by minimizing the penalized least squares function

\[
\frac{1}{n} \sum_{i=1}^{n} (y_i - f(x_i) - z_i \beta)^2 + \lambda J_m(f)
\]
There are several ways to define $J_m(f)$. For the thin-plate smoothing spline, with $x$ of dimension $d$, define $J_m(f)$ as

$$J_m(f) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \sum_{\alpha_1! \cdots \alpha_d!} \left[ \frac{\partial^m f}{\partial x_{1}^{\alpha_1} \cdots \partial x_{d}^{\alpha_d}} \right]^2 dx_1 \cdots dx_d$$

where $\sum \alpha_i = m$.

When $d = 2$ and $m = 2$, $J_2(f)$ is as follows:

$$J_2(f) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left[ \left( \frac{\partial^2 f}{\partial x_1^2} \right)^2 + 2 \left( \frac{\partial^2 f}{\partial x_1 \partial x_2} \right)^2 + \left( \frac{\partial^2 f}{\partial x_2^2} \right)^2 \right] dx_1 dx_2$$

In general, $m$ and $d$ must satisfy the condition that $2m - d > 0$. For the sake of simplicity, the formulas and equations that follow assume $m = 2$. Refer to Wahba (1990) and Bates et al. (1987) for more details.

Duchon (1976) showed that $f_\lambda$ can be represented as

$$f_\lambda(x_i) = \theta_0 + \sum_{j=1}^{d} \theta_j x_{ij} + \sum_{j=1}^{n} \delta_j E_2(x_i - x_j)$$

where $E_2(s) = \frac{1}{2\pi} ||s||^2 \ln(||s||)$.

If you define $K = (K)_{ij} = E_2(x_i - x_j)$ and $T = (T)_{ij} = (x_{ij})$, the goal is to find coefficients $\beta, \theta$, and $\delta$ that minimize

$$S_\lambda(\beta, \theta, \delta) = \frac{1}{n} ||y - T\theta - K\delta - Z\beta||^2 + \lambda \delta^T K \delta$$

A unique solution is guaranteed if the matrix $T$ is of full rank and $\delta^T K \delta \geq 0$.

If $\alpha = \left( \begin{array}{c} \theta \\ \beta \end{array} \right)$ and $X = (T : Z)$, the expression for $S_\lambda$ becomes

$$\frac{1}{n} ||y - X\alpha - K\delta||^2 + \lambda \delta^T K \delta$$

The coefficients $\alpha$ and $\delta$ can be obtained by solving

$$(K + n\lambda I_n)\delta + X\alpha = y$$

$$X^T \delta = 0$$

To compute $\alpha$ and $\delta$, let the QR decomposition of $X$ be

$$X = (Q_1 : Q_2) \begin{pmatrix} R \\ 0 \end{pmatrix}$$
where \((Q_1 : Q_2)\) is an orthogonal matrix and \(R\) is upper triangular, with \(X^T Q_2 = 0\) (Dongarra et al. 1979).

Since \(X^T \delta = 0\), \(\delta\) must be in the column space of \(Q_2\). Therefore, \(\delta\) can be expressed as \(\delta = Q_2 \gamma\) for a vector \(\gamma\). Substituting \(\delta = Q_2 \gamma\) into the preceding equation and multiplying through by \(Q_2^T\) gives

\[
Q_2^T (K + n \lambda I_n) Q_2 \gamma = Q_2^T y
\]

or

\[
\delta = Q_2 \gamma = Q_2 [Q_2^T (K + n \lambda I_n) Q_2]^{-1} Q_2^T y
\]

The coefficient \(\alpha\) can be obtained by solving

\[
R \alpha = Q_1^T [y - (K + n \lambda I_n) \delta]
\]

The influence matrix \(A(\lambda)\) is defined as

\[
\hat{y} = A(\lambda) y
\]

and has the form

\[
A(\lambda) = I - n \lambda Q_2 [Q_2^T (K + n \lambda I_n) Q_2]^{-1} Q_2^T
\]

Similar to the regression case, and if you consider the trace of \(A(\lambda)\) as the degrees of freedom for the information signal and the trace of \((I_n - A(\lambda))\) as the degrees of freedom for the noise component, the estimate \(\sigma^2\) can be represented as

\[
\hat{\sigma}^2 = \frac{\text{RSS}(\lambda)}{\text{Trace}(I_n - A(\lambda))}
\]

where \(\text{RSS}(\lambda)\) is the residual sum of squares. Theoretical properties of these estimates have not yet been published. However, good numerical results in simulation studies have been described by several authors. For more information, refer to O’Sullivan and Wong (1987), Nychka (1986a, 1986b, and 1988), and Hall and Titterington (1987).

**Confidence Intervals**

Viewing the spline model as a Bayesian model, Wahba (1983) proposed Bayesian confidence intervals for smoothing spline estimates as follows:

\[
\hat{f}_\lambda(x_i) \pm z_{\alpha/2} \sqrt{\hat{\sigma}^2 a_{ii}(\lambda)}
\]
where \( a_{ii}(\lambda) \) is the \( i \)th diagonal element of the \( A(\lambda) \) matrix and \( z_{\alpha/2} \) is the \( \alpha/2 \) point of the normal distribution. The confidence intervals are interpreted as intervals “across the function” as opposed to point-wise intervals.

Suppose that you fit a spline estimate to experimental data that consists of a true function \( f \) and a random error term, \( \epsilon_i \). In repeated experiments, it is likely that about \( 100(1 - \alpha)\% \) of the confidence intervals cover the corresponding true values, although some values are covered every time and other values are not covered by the confidence intervals most of the time. This effect is more pronounced when the true surface or surface has small regions of particularly rapid change.

**Smoothing Parameter**

The quantity \( \lambda \) is called the smoothing parameter, which controls the balance between the goodness of fit and the smoothness of the final estimate.

A large \( \lambda \) heavily penalizes the \( m \)th derivative of the function, thus forcing \( f^{(m)} \) close to 0. A small \( \lambda \) places less of a penalty on rapid change in \( f^{(m)}(x) \), resulting in an estimate that tends to interpolate the data points.

The smoothing parameter greatly affects the analysis, and it should be selected with care. One method is to perform several analyses with different values for \( \lambda \) and compare the resulting final estimates.

A more objective way to select the smoothing parameter \( \lambda \) is to use the “leave-out-one” cross validation function, which is an approximation of the predicted mean squares error. A generalized version of the leave-out-one cross validation function is proposed by Wahba (1990) and is easy to calculate. This Generalized Cross Validation (GCV) function \( V(\lambda) \) is defined as

\[
V(\lambda) = \frac{(1/n)||I - A(\lambda)||^2}{[(1/n)tr(I - A(\lambda))]^2}
\]

The justification for using the GCV function to select \( \lambda \) relies on asymptotic theory. Thus, you cannot expect good results for very small sample sizes or when there is not enough information in the data to separate the information signal from the noise component. Simulation studies suggest that for independent and identically distributed Gaussian noise, you can obtain reliable estimates of \( \lambda \) for \( n \) greater than 25 or 30. Note that, even for large values of \( n \) (say \( n \geq 50 \)), in extreme Monte Carlo simulations there may be a small percentage of unwarranted extreme estimates in which \( \hat{\lambda} = 0 \) or \( \hat{\lambda} = \infty \) (Wahba 1983). Generally, if \( \sigma^2 \) is known to within an order of magnitude, the occasional extreme case can be readily identified. As \( n \) gets larger, the effect becomes weaker.

The GCV function is fairly robust against nonhomogeneity of variances and non-Gaussian errors (Villalobos and Wahba 1987). Andrews (1988) has provided favorable theoretical results when variances are unequal. However, this selection method is likely to give unsatisfactory results when the errors are highly correlated.

The GCV value may be suspect when \( \lambda \) is extremely small because computed values may become indistinguishable from zero. In practice, calculations with \( \lambda = 0 \)
or λ near 0 can cause numerical instabilities resulting in an unsatisfactory solution. Simulation studies have shown that a λ with \( \log_{10}(n\lambda) > -8 \) is small enough that the final estimate based on this λ almost interpolates the data points. A GCV value based on a \( \lambda \leq 10^{-8} \) may not be accurate.

### ODS Tables Produced by PROC TPSPLINE

PROC TPSPLINE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

<table>
<thead>
<tr>
<th>ODS Table Name</th>
<th>Description</th>
<th>Statement</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataSummary</td>
<td>Data summary</td>
<td>PROC</td>
<td>default</td>
</tr>
<tr>
<td>FitSummary</td>
<td>Fit parameters and fit summary</td>
<td>PROC</td>
<td>default</td>
</tr>
<tr>
<td>FitStatistics</td>
<td>Model fit statistics</td>
<td>PROC</td>
<td>default</td>
</tr>
<tr>
<td>GCVFunction</td>
<td>GCV table</td>
<td>MODEL</td>
<td>LOGNLAMBDA, LAMBDA</td>
</tr>
</tbody>
</table>

By referring to the names of such tables, you can use the ODS OUTPUT statement to place one or more of these tables in output data sets.

For example, the following statements create an output data set named FitStats containing the FitStatistics table, an output data set named DataInfo containing the DataSummary table, an output data set named ModelInfo containing the FitSummary and an output data set named GCVFunc containing the GCVFunction.

```plaintext
proc tpspline data=Melanoma;
  model Incidences=Year /LOGNLAMBDA=(-4 to 0 by 0.2);
  ods output FitStatistics = FitStats
    DataSummary = DataInfo
    FitSummary = ModelInfo
    GCVFunction = GCVFunc;
run;
```

### Examples

#### Example 74.1. Partial Spline Model Fit

The following example analyzes the data set Measure that was introduced in the “Getting Started” section on page 4499. That analysis determined that the final estimated surface can be represented by a quadratic function for one or both of the independent variables. This example illustrates how you can use PROC TPSPLINE to fit a partial spline model. The data set Measure is fit using the following model:

\[
f(x_1, x_2) = 1 + x_1 + x_1^2 + h(x_2)
\]
The model has a parametric component (associated with the $x_1$ variable) and a non-parametric component (associated with the $x_2$ variable). The following statements fit a partial spline model.

```sas
data Measure;
  set Measure;
  x1sq = x1*x1;
run;

data pred;
  do x1=-1 to 1 by 0.1;
    do x2=-1 to 1 by 0.1;
      x1sq = x1*x1;
      output;
    end;
  end;
run;

proc tpspline data= measure;
  model y = x1 x1sq (x2);
  score data = pred 
    out = predy;
run;
```

Output 74.1.1 displays the results from these statements.

**Output 74.1.1.** Output from PROC TPSPLINE  

<table>

<tr>
<td>Dependent Variable: y</td>
</tr>
</tbody>
</table>

**Summary of Input Data Set**

- Number of Non-Missing Observations: 50
- Number of Missing Observations: 0
- Unique Smoothing Design Points: 5

**Summary of Final Model**

- Number of Regression Variables: 2
- Number of Smoothing Variables: 1
- Order of Derivative in the Penalty: 2
- Dimension of Polynomial Space: 4

**Summary Statistics of Final Estimation**

- log10(n*Lambda): -2.2374
- Smoothing Penalty: 205.3461
- Residual SS: 8.5821
- Tr(I-A): 43.1534
- Model DF: 6.8466
- Standard Deviation: 0.4460
As displayed in Output 74.1.1, there are five unique design points for the smoothing variable \( x_2 \) and two regression variables in the model \((x_1, x_1^2)\). The dimension of the null space (polynomial space) is 4. The standard deviation of the estimate is much larger than the one based on the model with both \( x_1 \) and \( x_2 \) as smoothing variables (0.445954 compared to 0.098421). One of the many possible explanations may be that the number of unique design points of the smoothing variable is too small to warrant an accurate estimate for \( h(x_2) \).

The following statements produce a surface plot for the partial spline model:

```plaintext
title 'Plot of Fitted Surface on a Fine Grid';
proc g3d data=predy;
    plot x2*x1=p_y/grid
        zmin=9
        zmax=21
        zticknum=4;
run;
```

The surface displayed in Output 74.1.2 is similar to the one estimated by using the full nonparametric model (displayed in Figure 74.5).

**Output 74.1.2.** Plot of TPSPLINE Fit from the Partial Spline Model
Example 74.2. Spline Model With Higher-Order Penalty

The following example continues the analysis of the data set Measure to illustrate how you can use PROC TPSPLINE to fit a spline model with a higher-order penalty term. Spline models with high-order penalty terms move low-order polynomial terms into the null space. Hence, there is no penalty for these terms, and they can vary without constraint.

As shown in the previous analyses, the final model for the data set Measure must include quadratic terms for both \( x_1 \) and \( x_2 \). This example fits the following model:

\[
f(x_1, x_2) = \theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_2 + \theta_4 x_2^2 + \theta_5 x_1 \cdot x_2 + g(x_1, x_2)
\]

The model includes quadratic terms for both variables, although it differs from the usual linear model. The nonparametric term \( g(x_1, x_2) \) explains the variation of the data unaccounted for by a simple quadratic surface.

To modify the order of the derivative in the penalty term, specify the `M=` option. The following statements specify the option `M=3` in order to include the quadratic terms in the null space:

```plaintext
data measure;
  set measure;
  x1sq = x1*x1;
  x2sq = x2*x2;
  x1x2 = x1*x2;
;
proc tpspline data= measure;
  model y = (x1 x2) / m=3;
  score data = pred
    out = predy;
run;
```

The output resulting from these statements is displayed in Output 74.2.1.
Output 74.2.1. Output from PROC TPSPLINE with $M=3$

The TPSPLINE Procedure

Dimension of Polynomial Space 6

Summary Statistics of Final Estimation
\[
\begin{align*}
\log_{10}(n*\lambda) & \quad -3.7831 \\
\text{Smoothing Penalty} & \quad 2092.4495 \\
\text{Residual SS} & \quad 0.2731 \\
\text{Tr}(I-A) & \quad 29.1716 \\
\text{Model DF} & \quad 20.8284 \\
\text{Standard Deviation} & \quad 0.0968
\end{align*}
\]

The model contains six terms in the null space. Compare Output 74.2.1 with Figure 74.2: the LOGNLAMBDA value and the smoothing penalty differ significantly. Note that, in general, these terms are not directly comparable for different models. The final estimate based on this model is close to the estimate based on the model using the default, $M=2$.

In the following statements, the REG procedure fits a quadratic surface model to the data set Measure.

```r
proc reg data= measure;
  model y = x1 x1sq x2 x2sq x1x2;
run;
```

The results are displayed in Output 74.2.2.
Output 74.2.2. Quadratic Surface Model: The REG Procedure

| Variable | DF | Parameter Estimate | Standard Error | t Value | Pr > |t| |
|----------|----|--------------------|----------------|---------|------|--------|
| Intercept| 1  | 14.90834           | 0.12519        | 119.09  | <.0001|
| x1       | 1  | 0.01292            | 0.09015        | 0.14    | 0.8867|
| x1sq     | 1  | -4.85194           | 0.15237        | -31.84  | <.0001|
| x2       | 1  | 0.02618            | 0.09015        | 0.29    | 0.7729|
| x2sq     | 1  | 5.20624            | 0.15237        | 34.17   | <.0001|
| x1x2     | 1  | -0.04814           | 0.12748        | -0.38   | 0.7076|

The REG procedure produces slightly different results. To fit a similar model with PROC TPSPLINE, you can use a MODEL statement specifying the degrees of freedom with the DF= option. You can also use a large value for the LOGNLAMBDA0= option to force a parametric model fit.

Because there is one degree of freedom for each of the following terms, Intercept, x1, x2, x1sq, x2sq, and x1x2, the DF=6 option is used.

```r
proc tpspline data=measure;
  model y=(x1 x2) /m=3 df=6 lognlambda=(-4 to 1 by 0.2);
  score data = pred
             out = predy;
run;
```

The results are displayed in Output 74.2.3. PROC TPSPLINE displays the list of GCV values for comparison.

</table>

Note: * indicates minimum GCV value.
The final estimate is based on 6.000330 degrees of freedom because there are already 6 degrees of freedom in the null space and the search range for lambda is not large enough (in this case, setting DF=6 is equivalent to setting lambda = $\infty$).

The standard deviation and RSS (Output 74.2.3) are close to the sum of squares for the error term and the root MSE from the the linear regression model (Output 74.2.2), respectively.

For this model, the optimal $\text{LOGNLAMBDA}$ is around $-3.8$, which produces a standard deviation estimate of 0.096765 (see Output 74.2.1) and a GCV value of 0.016051, while the model specifying DF=6 results in a $\text{LOGNLAMBDA}$ larger than 1 and a GCV value larger than 0.23074. The nonparametric model, based on the GCV, should provide better prediction, but the linear regression model can be more easily interpreted.

**Example 74.3. Multiple Minima of the GCV Function**

The following data represent the deposition of sulfate ($SO_4$) at 179 sites in 48 contiguous states of the United States in 1990. Each observation records the latitude and longitude of the site as well as the $SO_4$ deposition at the site measured in gram per square meter ($g/m^2$).

You can use PROC TPSPLINE to fit a surface that reflects the general trend and that reveals underlying features of the data.

```sas
data so4;
    input latitude longitude so4 @@;
datalines;
32.45833 87.24222 1.403 34.28778 85.96889 2.103
33.07139 109.86472 0.299 36.07167 112.15500 0.304

43.87333 104.19222 0.306 44.91722 110.42028 0.210
45.07611 72.67556 2.646

data pred;
  do latitude = 25 to 47 by 1;
    do longitude = 68 to 124 by 1;
      output;
    end;
  end;
run;

The preceding statements create the SAS data set so4 and the data set pred in order to make predictions on a regular grid. The following statements fit a surface for SO₄ deposition. The ODS OUTPUT statement creates a data set called GCV to contain the GCV values for LOGNLAMBDA in the range from −6 to 1.

proc tpspline data=so4;
  ods output GCVFunction=gcv;
  model so4 = (latitude longitude) /lognlambda=(-6 to 1 by 0.1);
  score data=pred out=prediction1;
run;

Partial output from these statements is displayed in Output 74.3.1.

Output 74.3.1. Partial Output from PROC TPSPLINE for Data Set SO4

The following statements produce Output 74.3.2:

```
symbol1 interpol=join value=none;
title "GCV Function";

proc gplot data=gcv;
   plot gcv*lognlambda/frame cframe=ligr
       vaxis=axis1 haxis=axis2;
run;
```

Output 74.3.2 displays the plot of the GCV function versus \( n_{\lambda} \) in \( \log_{10} \) scale. The GCV function has two minima. PROC TPSPLINE locates the minimum at 0.277005. The figure also displays a local minimum located around -2.56. Note that the TPSPLINE procedure may not always find the global minimum, although it did in this case.

**Output 74.3.2.** GCV Function of SO4 Data Set

The following analysis specifies the option LOGNLAMBDAA0=-2.56. The output is displayed in Output 74.3.3.

```
proc tpspline data=so4;
   model so4 = (latitude longitude) /lognlambda0=-2.56;
   score data=pred out=prediction2;
run;
```
Output 74.3.3.  Output from PROC TPSPLINE for Data Set SO4 with LOGNLAMBD$= -2.56$

The smoothing penalty is much larger in Output 74.3.3 than that displayed in Output 74.3.1. The estimate in Output 74.3.1 uses a large lambda value and, therefore, the surface is smoother than the estimate using LOGNLAMBD$= -2.56$ (Output 74.3.3).

The estimate based on LOGNLAMBD$= -2.56$ has a larger value for the degrees of freedom, and it has a much smaller standard deviation.

However, a smaller standard deviation in nonparametric regression does not necessarily mean that the estimate is good: a small $\lambda$ value always produces an estimate closer to the data and, therefore, a smaller standard deviation.

The following statements produce two contour plots of the estimates using the GCONTOUR procedure. In the final step, the plots are placed into a single graphic with the GREPLAY procedure.
title "TPSPLINE fit with lognlambda=0.277";
proc gcontour data=prediction1 gout=grafcat;
   plot latitude*longitude = P_so4/
      name="tpscon1" legend=legend1
      vaxis=axis1 haxis=axis2 cframe=ligr hreverse;
run;

title "TPSPLINE fit with lognlambda=-2.56";
proc gcontour data=prediction2 gout=grafcat;
   plot latitude*longitude = P_so4/
      name="tpscon2" legend=legend1
      vaxis=axis1 haxis=axis2 cframe=ligr hreverse;
run;

title;
proc greplay igout=grafcat tc=sashelp.templt template=v2 nofs;
   treplay 1:tpscon1 2:tpscon2;
quit;

Compare the two estimates by examining the contour plots of both estimates (Output 74.3.4).

Output 74.3.4. Contour Plot of TPSPLINE Estimates with Different Lambdas

As the contour plots show, the estimate with LOGNLAMBDAs=0.277 may repre-
sent the underlying trend, while the estimate with the LOGNLAMBDA=-2.56 is very rough and may be modeling the noise component.

Example 74.4. Large Data Set Application

The following example illustrates how you can use the D= option to decrease the computation time needed by the TPSPLINE procedure. Note that, while the D= option can be helpful in decreasing computation time for large data sets, it may produce unexpected results when used with small data sets.

The following statements generate the data set `large`:

```sql
data large;
  do x=-5 to 5 by 0.02;
    y=5*sin(3*x)+1*rannor(57391);
    output;
  end;
run;
```

The data set `large` contains 501 observations with one independent variable `x` and one dependent variable `y`. The following statements invoke PROC TPSPLINE to produce a thin-plate smoothing spline estimate and the associated 99% confidence interval. The output statistics are saved in the data set `fit1`.

```sql
proc tpspline data=large;
  model y = (x) / lambda=(-5 to -1 by 0.2) alpha=0.01;
  output out=fit1 pred lclm uclm;
run;
```

The results from this MODEL statement are displayed in Output 74.4.1.
Output 74.4.1.  Output from PROC TPSPLINE without the D= Option

       UCLM_y*x=4/overlay legend=legend1
       vaxis=axis1 haxis=axis2
       frame cframe=ligr;
run;
```
Example 74.5. Computing a Bootstrap Confidence Interval

The following example illustrates how you can construct a bootstrap confidence interval by using the multiple responses feature in PROC TPSPLINE.

Numerous epidemiological observations have indicated that exposure to solar radiation is an important factor in the etiology of melanoma. The following data present age-adjusted melanoma incidences for 37 years from the Connecticut Tumor Registry (Houghton, Flannery, and Viola 1980). The data are analyzed by Ramsay and Silverman (1997).
data melanoma;
  input year incidences @@;
datalines;
  1936 0.9 1937 0.8 1938 0.8 1939 1.3
  1940 1.4 1941 1.2 1942 1.7 1943 1.8
  1944 1.6 1945 1.5 1946 1.5 1947 2.0
  1948 2.5 1949 2.7 1950 2.9 1951 2.5
  1952 3.1 1953 2.4 1954 2.2 1955 2.9
  1956 2.5 1957 2.6 1958 3.2 1959 3.8
  1960 4.2 1961 3.9 1962 3.7 1963 3.3
  1964 3.7 1965 3.9 1966 4.1 1967 3.8
  1968 4.7 1969 4.4 1970 4.8 1971 4.8
  1972 4.8
; run;

The variable incidences records the number of melanoma cases per 100,000 people for the years 1936 to 1972. The following model fits the data and requests a 90% Bayesian confidence interval along with the estimate.

```sas
proc tpspline data=melanoma;
  model incidences = (year) /alpha = 0.1;
  output out = result pred uclm lclm;
run;
```

The output is displayed in Output 74.5.1

       vaxis=axis1 haxis=axis2  
       frame cframe=ligr;  
run;  
```

The estimated curve is displayed with 90% confidence interval bands in Output 74.5.2. The number of melanoma incidences exhibits a periodic pattern and increases over the years. The periodic pattern is related to sunspot activity and the accompanying fluctuations in solar radiation.
Wang and Wahba (1995) compared several bootstrap confidence intervals to Bayesian confidence intervals for smoothing splines. Both bootstrap and Bayesian confidence intervals are across-the-curve intervals, not point-wise intervals. They concluded that bootstrap confidence intervals work as well as Bayesian intervals concerning average coverage probability. Additionally, bootstrap confidence intervals appear to be better for small sample sizes. Based on their simulation, the “percentile-t interval” bootstrap interval performs better than the other types of bootstrap intervals.

Suppose that \( \hat{f}_\lambda \) and \( \hat{\sigma} \) are the estimates of \( f \) and \( \sigma \) from the data. Assume that \( \hat{f}_\lambda \) is the “true” \( f \), and generate the bootstrap sample as follows:

\[
y_i^* = \hat{f}_\lambda(x_i) + \epsilon_i^*, \quad i = 1, \ldots, n
\]

where \( \epsilon^* = (\epsilon_1^*, \ldots, \epsilon_n^*)^T \approx \mathcal{N}(0, \hat{\sigma} \mathbf{I}_{n \times n}) \). Denote \( f_{\lambda}^*(x_i) \) as the random variable of the bootstrap estimate at \( x_i \). Repeat this process \( K \) times, so that at each point \( x_i \), you have \( K \) bootstrap estimates \( \hat{f}_\lambda(x_i) \) or \( K \) realizations of \( f_{\lambda}^*(x_i) \). For each fixed \( x_i \), consider the following statistic \( D_i^* \), which is similar to a Student’s \( t \) statistic:

\[
D_i^* = (f_{\lambda}^*(x_i) - \hat{f}_\lambda(x_i))/\hat{\sigma}_i^*
\]
where $\hat{\sigma}^*_i$ is the estimate of $\hat{\sigma}$ based on the $i$th bootstrap sample.

Suppose $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ are the lower and upper $\alpha/2$ points of the empirical distribution of $D^*_i$. The $(1 - \alpha)100\%$ bootstrap confidence interval is defined as

$$(\hat{f}_{\hat{\lambda}}(x_i) - \chi_{1-\alpha/2}\hat{\sigma}, \hat{f}_{\hat{\lambda}}(x_i) - \chi_{\alpha/2}\hat{\sigma})$$

Bootstrap confidence intervals are easy to interpret and can be used with any distribution. However, because they require $K$ model fits, their construction is computationally intensive.

The multiple dependent variables feature in PROC TPSPLINE enables you to fit multiple models with the same independent variables. The procedure calculates the matrix decomposition part of the calculations only once regardless of the number of dependent variables in the model. These calculations are responsible for most of the computing time used by the TPSPLINE procedure. This feature is particularly useful when you need to generate a bootstrap confidence interval.

To construct a bootstrap confidence interval, perform the following tasks:

- Fit the data using PROC TPSPLINE and obtain estimates $\hat{f}_{\hat{\lambda}}(x_i)$ and $\hat{\sigma}$.
- Generate $K$ bootstrap samples based on $\hat{f}_{\hat{\lambda}}(x_i)$ and $\hat{\sigma}$.
- Fit the $K$ bootstrap samples with the TPSPLINE procedure to obtain estimates of $\hat{f}^*_\hat{\lambda}(x_i)$ and $\hat{\sigma}^*_i$.
- Compute $D^*_i$ and the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$.

The following statements illustrate this process:

```plaintext
proc tpspline data=melanoma;
  model incidences = (year) /alpha = 0.05;
  output out = result pred uclm lclm;
run;
```

The output from the initial PROC TPSPLINE analysis is displayed in Output 74.5.3. The data set result contains the predicted values and confidence limits from the analysis.

The following statements illustrate how you can obtain a bootstrap confidence interval for the Melanoma data. The following statements create the data set bootstrap. The observations are created with information from the preceding PROC TPSPLINE execution; as displayed in Output 74.5.3, $\hat{\sigma} = 0.232823$. The values of $\hat{f}_\lambda(x_i)$ are stored in the data set result in the variable P_incidence.

```r
data bootstrap;
  set result;
  array y{1070} y1-y1070;
  do i=1 to 1070;
    y{i} = p_incidences + 0.232823*rannor(123456789);
  end;
  keep y1-y1070 p_incidences year;
run;
```

```r
ods listing close;
proc tpspline data=bootstrap;
  ods output FitStatistics=FitResult;
  id p_incidences;
  model y1-y1070 = (year);
  output out=result2;
run;
ods listing;
```

The DATA step generates 1,070 bootstrap samples based on the previous estimate from PROC TPSPLINE. For this data set, some of the bootstrap samples result in $\lambda$s
Example 74.5. Computing a Bootstrap Confidence Interval

(selected by the GCV function) that cause problematic behavior. Thus, an additional 70 bootstrap samples are generated.

The ODS listing destination is closed before PROC TPSPLINE is invoked. The model fits all the $y_1$–$y_{1070}$ variables as dependent variables, and the models are fit for all bootstrap samples simultaneously. The output data set result2 contains the variables year, $y_1$–$y_{1070}$, $p_{-y_1}$–$p_{-y_{1070}}$, and $P_{\text{incidences}}$.

The ODS OUTPUT statement writes the FitStatistics table to the data set FitResult. The data set FitResult contains the two variables. They are Parameter and Value. The FitResult data set is used in subsequent calculations for $D_1^*$. 

In the data set FitResult, there are 63 estimates with a standard deviation of zero, suggesting that the estimates provide perfect fits of the data and are caused by $\hat{\lambda}$s that are approximately equal to zero. For small sample sizes, there is a positive probability that the $\lambda$ chosen by the GCV function will be zero (refer to Wang and Wahba 1995).

In the following steps, these cases are removed from the bootstrap samples as “bad” samples: they represent failure of the GCV function.

The following SAS statements manipulate the data set FitResult, retaining the standard deviations for all bootstrap samples and merging FitResult with the data set result2, which contains the estimates for bootstrap samples. In the final data set boot, the $D_1^*$ statistics are calculated.

```sas
data FitResult; set FitResult;
   if Parameter="Standard Deviation";
       keep Value;
run;

proc transpose data=FitResult out=sd prefix=sd;

data result2;
   if _N_ = 1 then set sd;
   set result2;

data boot;
   set result2;
   array y[1070] p_y1-p_y1070;
   array sd[1070] sd1-sd1070;
   do i=1 to 1070;
      if sd{i} > 0 then do;
         d = (y{i} - P_{\text{incidences}})/sd{i};
         obs = _N_;
         output;
      end;
   end;
   keep d obs P_{\text{incidences}} year;
run;
```

The following SAS statements retain the first 1000 bootstrap samples and calculate the values $\chi_{\alpha/2}$ and $\chi_{1-\alpha/2}$ with $\alpha = 0.1$. 

```sas
```
The data set result contains the variables year, incidences, the TPSPLINE estimate
P_incidences, and the 90% Bayesian and 90% bootstrap confidence intervals.

The following statements produce Output 74.5.4:

```sas
symbol1 v=dot h=1pct;
symbol2 i=join v=none l=1;
symbol3 i=join v=none l=33;
symbol4 i=join v=none l=33;
symbol5 i=join v=none l=43 c=green;
symbol6 i=join v=none l=43 c=green;

title1 'Age-adjusted Melanoma Incidences for 37 years';
proc gplot data=result;
plot incidences * year=1
  p_incidences * year=2
  lclm_incidences * year=3
  uclm_incidences * year=3
  lower * year=4
  upper * year=4
/overlay legend=legend1
  vaxis=axis1 haxis=axis2
  frame cframe=ligr;
run;
```

Output 74.5.4 displays the plot of the variable incidences, the predicted values, and the Bayesian and bootstrap confidence intervals.

The plot shows that the bootstrap confidence interval is similar to the Bayesian confidence interval. However, the Bayesian confidence interval is symmetric around the estimates, while the bootstrap confidence interval is not.
Output 74.5.4. Comparison of Bayesian and Bootstrap Confidence Interval for Melanoma Data

![Graph showing age-adjusted melanoma incidences for 37 years with various confidence intervals.]

Chapter 75
The TRANSREG Procedure

Overview

The TRANSREG (transformation regression) procedure fits linear models, optionally with spline and other nonlinear transformations, and it can be used to code experimental designs prior to their use in other analyses.

The TRANSREG procedure fits many types of linear models, including

- ordinary regression and ANOVA
- metric and nonmetric conjoint analysis (Green and Wind 1975; de Leeuw, Young, and Takane 1976)
- metric and nonmetric vector and ideal point preference mapping (Carroll 1972)
- simple, multiple, and multivariate regression with variable transformations (Young, de Leeuw, and Takane 1976; Winsberg and Ramsay 1980; Breiman and Friedman 1985)
- redundancy analysis (Stewart and Love 1968) with variable transformations (Israels 1984)
- canonical correlation analysis with variable transformations (van der Burg and de Leeuw 1983)
- response surface regression (Meyers 1976; Khuri and Cornell 1987) with variable transformations
- linear models with Box-Cox (1964) transformations of the dependent variables

The data set can contain variables measured on nominal, ordinal, interval, and ratio scales (Siegel 1956). Any mix of these variable types is allowed for the dependent and independent variables. The TRANSREG procedure can transform

- nominal variables by scoring the categories to minimize squared error (Fisher 1938), or they can be expanded into dummy variables
- ordinal variables by monotonically scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and squared error is minimized. Ties can be optimally untied or left tied (Kruskal 1964). Ordinal variables can also be transformed to ranks.
- interval and ratio scale of measurement variables linearly or nonlinearly with spline (de Boor 1978; van Rijckevoorsel 1982) or monotone spline (Winsberg and Ramsay 1980) transformations. In addition, smooth, logarithmic, exponential, power, logit, and inverse trigonometric sine transformations are available.
Transformations produced by the PROC TRANSREG multiple regression algorithm, requesting spline transformations, are often similar to transformations produced by the ACE smooth regression method of Breiman and Friedman (1985). However, ACE does not explicitly optimize a loss function (de Leeuw 1986), while PROC TRANSREG always explicitly optimizes a squared-error loss function.

PROC TRANSREG extends the ordinary general linear model by providing optimal variable transformations that are iteratively derived using the method of alternating least squares (Young 1981). PROC TRANSREG iterates until convergence, alternating

- finding least-squares estimates of the parameters of the model given the current scoring of the data (that is, the current vectors)
- finding least-squares estimates of the scoring parameters given the current set of model parameters

For more background on alternating least-squares optimal scaling methods and transformation regression methods, refer to Young, de Leeuw, and Takane (1976), Winsberg and Ramsay (1980), Young (1981), Gifi (1990), Schiffman, Reynolds, and Young (1981), van der Burg and de Leeuw (1983), Israels (1984), Breiman and Friedman (1985), and Hastie and Tibshirani (1986). (These are just a few of the many relevant sources.)

**Getting Started**

This section provides several examples that illustrate features of the TRANSREG procedure.

**Main-Effects ANOVA**

This example shows how to use the TRANSREG procedure to code and fit a main-effects ANOVA model. The input data set contains the dependent variables \( Y \), factors \( X_1 \) and \( X_2 \), and 11 observations. The following statements perform a main-effects ANOVA:

```plaintext

Figure 75.1. ANOVA Example Output from PROC TRANSREG

The iteration history in Figure 75.1 shows that the final R-Square of 0.88144 is reached on the first iteration.
This is followed by ANOVA, fit statistics, and regression tables. PROC TRANSREG uses an effects (also called deviations from means or 0, 1, -1) coding in this example.

For more information on using PROC TRANSREG for ANOVA and other codings, see the “ANOVA Codings” section on page 4662.

The TRANSREG procedure produces the data set displayed in Figure 75.2.

### Figure 75.2. Output Data Set from PROC TRANSREG

The output data set has three kinds of observations, identified by values of _TYPE_.

- When _TYPE_='SCORE’, the observation contains information on the dependent and independent variables as follows:
  - Y is the original dependent variable.
  - X1 and X2 are the independent classification variables, and the Intercept through X2 a columns contain the main effects design matrix that PROC TRANSREG creates. The variable names are Intercept, X1a, X1b, and X2a. Their labels are shown in the listing.
- When _TYPE_='M COEFFI’, the observation contains coefficients of the final linear model.
- When _TYPE_='MEAN’, the observation contains the marginal means.

The observations with _TYPE_='SCORE’ form the score partition of the data set, and the observations with _TYPE_='M COEFFI’ and _TYPE_='MEAN’ form the coefficient partition of the data set.
Detecting Nonlinear Relationships

The TRANSREG procedure can detect nonlinear relationships among variables. For example, suppose 400 observations are generated from the following function

\[ t = \frac{x}{4} + \sin(x) \]

and data are created as follows

\[ y = t + \epsilon \]

where \( \epsilon \) is random normal error.

The following statements find a cubic spline transformation of \( X \) with four knots. For information on using splines and knots, see the “Smoothing Splines” section on page 4596, the “Solving Standard Least-Squares Problems” section on page 4628, Example 75.1, and Example 75.4.

The following statements produce Figure 75.3 through Figure 75.4:

```plaintext
title 'Curve Fitting Example';

*---Create An Artificial Nonlinear Scatter Plot---;
data Curve;
    Pi=constant('pi');
    Pi4=4*Pi;
    Increment=Pi4/400;
    do X=Increment to Pi4 by Increment;
        T=X/4 + sin(X);
        Y=T + normal(7);
        output;
    end;
run;

*---Request a Spline Transformation of X---;
proc transreg data=Curve dummy;
    model identity(Y)=spline(X / nknots=4);
    output predicted;
    id T;
run;

*---Plot the Results---;
goptions goutmode=replace nodisplay;
%let opts = haxis=axis2 vaxis=axis1 frame=cframe=ligr;
* Depending on your goptions, these plot options may work better:
* %let opts = haxis=axis2 vaxis=axis1 frame;
proc gplot;
    title;
    axis1 minor=none label=(angle=90 rotate=0);
```
axis2 minor=none;
plot T*X=2 / &opts name='tregin1';
plot Y*X=1 / &opts name='tregin2';
plot Y*X=1 T*X=2 PY*X=3 / &opts name='tregin3' overlay ;
symbol1 color=blue  v=star i=none;

symbol2 color=yellow v=none i=join line=1;
symbol3 color=red   v=none i=join line=2;
run; quit;
goptions display;
proc greply nofs tc=sashelp.templt template=l2r2;
  igout gseg;
    treplay 1:tregin1 2:tregin3 3:tregin2;
run; quit;

PROC TRANSREG increases the squared multiple correlation from the original value of 0.19945 to 0.47062. The plot of $T$ by $X$ shows the original function, the plot of $Y$ by $X$ shows the error-perturbed data, and the third plot shows the data, the true function as a solid curve, and the regression function as the dashed curve. The regression function closely approximates the true function.

PROC TRANSREG Statement

The PROC TRANSREG statement starts the TRANSREG procedure. Optionally, this statement identifies an input and an OUTTEST= data set, specifies the algorithm and other computational details, requests displayed output, and controls the contents of the OUT= data set (which is created with the OUTPUT statement). The DATA= and OUTTEST= options can appear only in the PROC TRANSREG statement.

The following table summarizes options available in the PROC TRANSREG statement. All a-options and o-options are described in the sections on either the MODEL or OUTPUT statement, in which these options can also be specified.

DATA= SAS-data-set

specifies the SAS data set to be analyzed. If you do not specify the DATA= option, PROC TRANSREG uses the most recently created SAS data set. The data set must be an ordinary SAS data set; it cannot be a special TYPE= data set.

OUTTEST= SAS-data-set

specifies an output data set to contain hypothesis tests results. When you specify the OUTTEST= option, the data set contains ANOVA results. When you specify the SS2  a-option, regression tables are also output. When you specify the UTILITIES  o-option, conjoint analysis part-worth utilities are also output. For more information on the OUTTEST= data set, see the “OUTTEST= Output Data Set” section on page 4626.

**BY Statement**

```sas
BY  variables ;
```

You can specify a BY statement with PROC TRANSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TRANSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.
FREQ Statement

FREQ variable ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable’s name in a FREQ statement. PROC TRANSREG then treats the data set as if each observation appeared \( n \) times, where \( n \) is the value of the FREQ variable for the observation. Noninteger values of the FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

ID Statement

ID variables ;

The ID statement includes additional character or numeric variables in the OUT= data set. The variables must be contained in the input data set.

MODEL Statement

MODEL < transform(dependents < / t-options >)
    < transform(dependents < / t-options >)...
    transform(independents < / t-options >)
    < transform(independents < / t-options >)...
> = >
</ a-options > ;

The MODEL statement specifies the dependent and independent variables (dependents and independents, respectively) and specifies the transformation (transform) to apply to each variable. Only one MODEL statement can appear in the TRANSREG procedure. The t-options are transformation options, and the a-options are the algorithm options. The t-options provide details for the transformation; these depend on the transform chosen. The t-options are listed after a slash in the parentheses that enclose the variable list (either dependents or independents). The a-options control the algorithm used, details of iteration, details of how the intercept and dummy variables are generated, and displayed output details. The a-options are listed after the entire model specification (the dependents, independents, transformations, and t-options) and after a slash. You can also specify the algorithm options in the PROC TRANSREG statement. When you specify the DESIGN a-option, dependents and an equal sign are not required. The operators “\(*\)”, “\(|\)”, and “@” from the GLM procedure are available for interactions with the CLASS expansion and the IDENTITY transformation.

Class(a * b ...
c | d ...
e | f ... @ n)
Identity(a * b ...
c | d ...
e | f ... @ n)
In addition, transformations and spline expansions can be crossed with classification variables:

\[
\text{transform}(\text{var}) * \text{class}(\text{group}) \\
\text{transform}(\text{var}) \mid \text{class}(\text{group})
\]

See the “Types of Effects” section on page 1784 in Chapter 32, “The GLM Procedure,” for a description of the @, *, and | operators and see the “Model Statement Usage” section on page 4592 for information on how to use these operators in PROC TRANSREG. Note that nesting is not allowed in PROC TRANSREG.

The next three sections discuss the transformations available ([transforms]) (see the “Families of Transformations” section on page 4558), the transformation options ([t-options]) (see the “Transformation Options ([t-options])” section on page 4564), and the algorithm options ([a-options]) (see the “Algorithm Options ([a-options])” section on page 4573).

**Families of Transformations**

In the MODEL statement, *transform* specifies a transformation in one of four families.

- **Variable expansions** preprocess the specified variables, replacing them with more variables.
- **Nonoptimal transformations** preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
- **Optimal transformations** replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable).
- **Other transformations** are the IDENTITY and SSPLINE transformations. These do not fit into the preceding categories.

The following table summarizes the transformations in each family.
You can use any transformation with either dependent or independent variables (except the SMOOTH transformation, which can be used only with independent variables, and BOXCOX, which can be used only with dependent variables). However, the variable expansions are usually more appropriate for independent variables.

The *transform* is followed by a variable (or list of variables) enclosed in parentheses. Optionally, depending on the *transform*, the parentheses can also contain *t-options*, which follow the variables and a slash. For example,

```
model log(y)=class(x);
```

finds a LOG transformation of Y and performs a CLASS expansion of X.

```
model identity(y) = spline(x1 x2 / nknots=3);
```
The preceding statement finds SPLINE transformations of $X_1$ and $X_2$. The NKNOTS= t-option used with the SPLINE transformation specifies three knots. The IDENTITY($Y$) transformation specifies that $Y$ is not to be transformed.

The rest of this section provides syntax details for members of the four families of transformations. The t-options are discussed in the “Transformation Options (t-options)” section on page 4564.

**Variable Expansions**

The TRANSREG procedure performs variable expansions before iteration begins. Variable expansions expand the original variables into a typically larger set of new variables. The original variables are those that are listed in parentheses after transform, and they are sometimes referred to by the name of the transform. For example, in CLASS($X_1$ $X_2$), $X_1$ and $X_2$ are sometimes referred to as CLASS expansion variables, and the expanded variables are referred to as dummy variables. Similarly, in POINT($Dim_1$ $Dim_2$), $Dim_1$ and $Dim_2$ are sometimes referred to as POINT variables.

The resulting variables are not transformed by the iterative algorithms after the initial preprocessing. Observations with missing values for these types of variables are excluded from the analysis.

The POINT, EPOINT, and QPOINT variable expansions are used in preference mapping analyses (also called PREFMAP, external unfolding, ideal point regression) (Carroll 1972) and for response surface regressions. These three expansions create circular, elliptical, and quadratic response or preference surfaces (see the “Point Models” section on page 4605 and Example 75.5). The CLASS variable expansion is used for main effects ANOVA.

The following list provides syntax and details for the variable expansion transforms.

**BSPLINE**

**BSP**

expands each variable to a B-spline basis. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY t-options with the BSPLINE expansion. When DEGREE= $n$ (3 by default) with $k$ knots (0 by default), $n + k + 1$ variables are created. In addition, the original variable appears in the OUT= data set before the ID variables. For example, BSPLINE($X$) expands $X$ into $X_0$ $X_1$ $X_2$ $X_3$ and outputs $X$ as well. The $X_-$: variables contain the B-spline (which are the same basis vectors that the SPLINE and MSPLINE transformations use internally). The columns of the BSPLINE expansion sum to a column of ones, so an implicit intercept model is fit when the BSPLINE expansion is specified. If you specify the BSPLINE expansion for more than one variable, the model is less than full rank. See the section “SPLINE, BSPLINE, and PSPLINE Comparisons” on page 4614. Variables following BSPLINE must be numeric, and they are typically continuous.

**CLASS**

**CLA**

expands the variables to a set of dummy variables. For example, CLASS($X_1$ $X_2$) is used for a simple main-effects model, CLASS($X_1$ | $X_2$) fits a main-effects and interactions model, and CLASS($X_1$|$X_2$|$X_3$|$X_4$@2 $X_1$*$X_2$*$X_3$) creates all main effects,
all two-way interactions, and one three-way interaction. See the “Model Statement Usage” section on page 4592 for information on how to use the operators @, *, and | in PROC TRANSREG. To determine class membership, PROC TRANSREG uses the values of the formatted variables. Variables following CLASS can be either character or numeric; numeric variables should be discrete.

EPOINT

EPO

expands the variables for an elliptical response surface regression or for an elliptical ideal point regression. Specify the COORDINATES o-option to output PREFMAP ideal elliptical point model coordinates to the OUT= data set. Each axis of the ellipse (or ellipsoid) is oriented in the same direction as one of the variables. The EPOINT expansion creates a new variable for each original variable. The value of each new variable is the square of each observed value for the corresponding parenthesized variable. The regression analysis then uses both sets of variables (original and squared). Variables following EPOINT must be numeric, and they are typically continuous.

POINT

POI

expands the variables for a circular response surface regression or for a circular ideal point regression. Specify the COORDINATES o-option to output PREFMAP ideal point model coordinates to the OUT= data set. The POINT expansion creates a new variable having a value for each observation that is the sums of squares of all the POINT variables. This new variable is added to the set of variables and is used in the regression analysis. For more on ideal point regression, refer to Carroll (1972). Variables following POINT must be numeric, and they are typically continuous.

PSPLINE

PSP

expands each variable to a piecewise polynomial basis. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY t-options with PSPLINE. When DEGREE=n (3 by default) with k knots (0 by default), n + k variables are created. In addition, the original variable appears in the OUT= data set before the ID variables. For example, PSPLINE(X / NKNOTS=1) expands X into X_1 X_2 X_3 X_4 and outputs X as well. Unlike BSPLINE, an intercept is not implicit in the columns of PSPLINE. Refer to Smith (1979) for a good introduction to piecewise polynomial splines. Also see the section “SPLINE, BSPLINE, and PSPLINE Comparisons” on page 4614. Variables following PSPLINE must be numeric, and they are typically continuous.

QPOINT

QPO

expands the variables for a quadratic response surface regression or for a quadratic ideal point regression. Specify the COORDINATES o-option to output PREFMAP quadratic ideal point model coordinates to the OUT= data set. For m QPOINT variables, m(m+1)/2 new variables are created containing the squares and crossproducts of the original variables. The regression analysis uses both sets (original and crossed). Variables following QPOINT must be numeric, and they are typically continuous.
Nonoptimal Transformations

Like variable expansions, nonoptimal transformations are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation with missing value estimation).

The following list provides syntax and details for nonoptimal variable transformations.

ARSIN
ARS
finds an inverse trigonometric sine transformation. Variables following ARSIN must be numeric, in the interval \((-1.0 \leq X \leq 1.0)\), and they are typically continuous.

BOXCOX
BOX
finds a Box-Cox transformation of the specified variables (see the “Box-Cox Transformations” section on page 4595 and Example 75.6). The BOXCOX transformation can be used only with dependent variables. The ALPHA=, CLL=, CONVENIENT, GEOMETRICMEAN, LAMBDA=, and PARAMETER= t-options can be used with the BOXCOX transformation. Variables following BOXCOX must be numeric, and they are typically continuous.

EXP
exponentiates variables (the variable \(X\) is transformed to \(a^X\)). To specify the value of \(a\), use the PARAMETER= t-option. By default, \(a\) is the mathematical constant \(e = 2.718...\). Variables following EXP must be numeric, and they are typically continuous.

LOG
transforms variables to logarithms (the variable \(X\) is transformed to \(\log_a(X)\)). To specify the base of the logarithm, use the PARAMETER= t-option. The default is a natural logarithm with base \(e = 2.718...\). Variables following LOG must be numeric and positive, and they are typically continuous.

LOGIT
finds a logit transformation on the variables. The logit of \(X\) is \(\log\left(\frac{X}{1-X}\right)\). Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables following LOGIT must be numeric, in the interval \((0.0 < X < 1.0)\), and they are typically continuous.

POWER
POW
raises variables to a specified power (the variable \(X\) is transformed to \(X^a\)). You must specify the power parameter \(a\) by specifying the PARAMETER= t-option following the variables:

\[
power(variable / parameter=number)
\]
You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=-1), square roots (PARAMETER=0.5), and so on. Variables following POWER must be numeric, and they are typically continuous.

**RANK**

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables following RANK must be numeric.

**SMOOTH**

is a noniterative smoothing spline transformation. You can specify the smoothing parameter with either the SM= or the PARAMETER= t-option. The default smoothing parameter is SM=0. Variables following SMOOTH must be numeric, and they are typically continuous. The SMOOTH transformation can be used only with independent variables. For more information, see the “Smoothing Splines” section on page 4596.

**Optimal Transformations**

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the “Missing Values” section on page 4599).

The following list provides syntax and details for optimal transformations.

**LINEAR**

finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables following LINEAR must be numeric.

**MONOTONE**

finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least-squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables following MONOTONE must be numeric, and they are typically discrete.

**MSPLINE**

finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY t-options with MSPLINE. By default, PROC TRANSREG uses a quadratic spline. Variables following MSPLINE must be numeric, and they are typically continuous.

**OPSCORE**

finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. Fisher’s (1938) optimal scoring method
is used. Variables following OPSCORE can be either character or numeric; numeric variables should be discrete.

**SPLINE**

*SPL* finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC TRANSREG uses a cubic polynomial transformation. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY t-options with SPLINE. Variables following SPLINE must be numeric, and they are typically continuous.

**UNTIE**

*UNT* finds a monotonic transformation of each variable without the restriction that ties are preserved. The TRANSREG procedure uses the Kruskal (1964) primary least-squares monotonic transformation method. This transformation weakly preserves order but not category membership (it may untie some previously tied values). Variables following UNTIE must be numeric, and they are typically discrete.

**Other Transformations**

**IDENTITY**

*IDE* specifies variables that are not changed by the iterations. Typically, the IDENTITY transformation is used with a simple variable list, such as IDENTITY(X1-X5). However, you can also specify interaction terms. For example, IDENTITY(X1 | X2) creates X1, X2, and the product X1*X2; and IDENTITY(X1 | X2 | X3) creates X1, X2, X1*X2, X3, X1*X3, X2*X3, and X1*X2*X3. See the “Model Statement Usage” section on page 4592 for information on how to use the operators @, *, and | in PROC TRANSREG.

The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT t-option, the ADDITIVE a-option, and the TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables. Variables following IDENTITY must be numeric.

**SSPLINE**

*SSP* finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= t-option or the PARAMETER= t-option. The default smoothing parameter is SM=0. Variables following SSPLINE must be numeric, and they are typically continuous.

**Transformation Options (t-options)**

If you use a nonoptimal, optimal, or other transformation, you can use t-options, which specify additional details of the transformation. The t-options are specified within the parentheses that enclose variables and are listed after a slash. You can use t-options with both dependent and independent variables. For example,
proc transreg;
   model identity(y)=spline(x / nknots=3);
   output;
run;

The preceding statements find an optimal variable transformation (SPLINE) of the independent variable, and they use a t-option to specify the number of knots (NKNOTS=). The following is a more complex example:

proc transreg;
   model m spline(y / nknots=3)=class(x1 x2 / effects);
   output;
run;

These statements find a monotone spline transformation (MSPLINE with three knots) of the dependent variable and perform a CLASS expansion with effects coding of the independents.

The following sections discuss the t-options available for nonoptimal, optimal, and other transformations.

The following table summarizes the t-options:

Table 75.2.  t-options Available in the MODEL Statement

Other t-options

| operations occur after the expansion | AFTER |
| centers before the analysis begins | CENTER |
| renames variables | NAME= |
| reflects the variable around the mean | REFLECT |
| specifies transformation standardization | TSTANDARD= |
| standardizes before the analysis begins | Z |

Nonoptimal Transformation t-options

ORIGINAL
ORI

matches the variable’s final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL t-option is available for all of the nonoptimal transformations.

Parameter t-options

PARAMETER=number
PAR=number

specifies the transformation parameter. The PARAMETER= t-option is available for the BOXCOX, EXP, LOG, POWER, SMOOTH, and SSPLINE transformations. For BOXCOX, the parameter is the value to add to each value of the BOXCOX variable before a Box-Cox transformation. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (You can specify a SAS/GRAFHS-style smoothing parameter with the SM= t-option.) The default for the PARAMETER= t-option for the BOXCOX transformation is 0 and for the LOG and EXP transformations is $e = 2.718 \ldots$. The default parameter for SMOOTH and SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= t-option; there is no default.

SM=n

specifies a SAS/GRAFHS-style smoothing parameter in the range 0 to 100. You can specify the SM= t-option only with the SMOOTH and SSPLINE transformations. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.

Spline t-options

The following t-options are available with the SPLINE and MSPLINE optimal transformations and the PSPLINE and BSPLINE expansions.
DEGREE=n

specifies the degree of the spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE, PSPLINE, and BSPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

EVENLY

EVE

is used with the NKNOTS= t-option to space the knots evenly. The differences between adjacent knots are constant.

If you specify NKNOTS=k, k knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k + 1))$$

for $i = 1, \ldots, k$. For example, if you specify

spline(X / knots=2 evenly)

and the variable X has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY t-option, the NKNOTS= t-option places knots at percentiles, so the knots are not evenly spaced.

EXKNOTS=number-list | n TO m BY p

EXK=number-list | n TO m BY p

specifies exterior knots for SPLINE and MSPLINE transformations and BSPLINE expansions. Usually, this option is not needed; PROC TRANSREG automatically picks suitable exterior knots. The only time you need to use this option is when you want to ensure that the exact same basis is used for different splines, for example when applying coefficients from one spline transformation to a variable in a different data set (see “Scoring Spline Variables” at the end of Example 75.1).

Specify one or two values. If the minimum EXKNOTS= value is less than the minimum data value, it is used as the exterior knot. If the maximum EXKNOTS= value is greater than the maximum data value, it is used as the exterior knot. Otherwise these values are ignored. When EXKNOTS= is specified with the CENTER or Z t-options, the knots apply to the original variable, not to the centered or standardized variable.

The B-spline transformations and expansions use a knot list consisting of exterior knots (values just smaller than the minimum), the specified (interior) knots, and exterior knots (values just larger than the minimum). You can use the DETAILS option to see all of these knots. Using different external knots gives different but equivalent B-spline bases. You can specify exterior knots on either the KNOTS= or EXKNOTS= t-options, however for the BSPLINE expansion, the KNOTS= t-option creates extra all-zero basis columns, whereas the EXKNOTS= t-option will give you the correct basis.
KNOTS=number-list | n TO m BY p
KNO=number-list | n TO m BY p

specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the \( n \)th (from DEGREE=\( n \)) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the \((n - 1)\)th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= t-option with the NKNOTS= t-option. You should keep the number of knots small (see the section “Specifying the Number of Knots” on page 4613).

NKNOTS=n
NKN=n
creates \( n \) knots, the first at the \( 100/(n + 1) \) percentile, the second at the \( 200/(n + 1) \) percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the twenty-fifth percentile, the median, and the seventy-fifth percentile. By default, NKNOTS=0. The NKNOTS= t-option must be \( \geq 0 \).

You cannot use the NKNOTS= t-option with the KNOTS= t-option.

You should keep the number of knots small (see the section “Specifying the Number of Knots” on page 4613).

CLASS Variable t-options

CPREFIX=n | number-list
CPR=n | number-list
specifies the number of first characters of a CLASS expansion variable’s name to use in constructing names for dummy variables. When CPREFIX= is specified as an a-option (see the description of the CPREFIX= a-option on page 4575) or an o-option, it specifies the default for all CLASS variables. When you specify CPREFIX= as a t-option, it overrides the default only for selected variables. A different CPREFIX= value can be specified for each CLASS variable by specifying the CPREFIX=number-list t-option, like the ZERO=formatted-value-list t-option.

DEVIATIONS
DEV
EFFECTS
EFF
requests a deviations-from-means coding of CLASS variables. The coded design matrix has values of 0, 1, and \(-1\) for reference levels. This coding is referred to as “deviations-from-means,” “effects,” “center-point,” or “full-rank” coding.

LPREFIX=n | number-list
LPR=n | number-list

specifies the number of first characters of a CLASS expansion variable’s label (or name if no label is specified) to use in constructing labels for dummy variables. When LPREFIX= is specified as an a-option (see the description of the LPREFIX= a-option on page 4575) or an o-option, it specifies the default for all CLASS variables. When you specify LPREFIX= as a t-option, it overrides the default only for selected variables. A different LPREFIX= value can be specified for each CLASS variable by specifying the LPREFIX=number-list t-option, like the ZERO=formatted-value-list t-option.
on page 4576) or an o-option, it specifies the default for all CLASS variables. When you specify LPREFIX= as a t-option, it overrides the default only for selected variables. A different LPREFIX= value can be specified for each CLASS variable by specifying the LPREFIX=number-list t-option, like the ZERO=formatted-value-list t-option.

**MODEL Statement**

**ORDER=DATA | FREQ | FORMATTED | INTERNAL**

ORDER=DAT | FRE | FOR | INT

specifies the order in which the CLASS variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When ORDER= is specified as an a-option (see the description of the ORDER= a-option on page 4578) or as an o-option, it specifies the default ordering for all CLASS variables. When you specify ORDER= as a t-option, it overrides the default ordering only for selected variables. You can specify a different ORDER= value for each CLASS specification.

**SEPARATORS='string-1 '<'string-2' '>'**

SEP='string-1 '<'string-2' >

specifies separators for creating CLASS expansion variable labels. By default, SEPARATORS=' ' ' * ' ("blank" and "blank asterisk blank"). When SEPARATORS= is specified as an a-option (see the description of the SEPARATORS= a-option on page 4579) or as an o-option, it specifies the default separators for all CLASS variables. When you specify SEPARATORS= as a t-option, it overrides the default only for selected variables. You can specify a different SEPARATORS= value for each CLASS specification.

**ZERO=FIRST | LAST | NONE | SUM**

ZER=FIR | LAS | NON | SUM

ZERO= 'formatted-value ' '<'formatted-value' ...'>

is used with CLASS variables. The default is ZERO=LAST.

The specification CLASS(variable / ZERO=FIRST) sets to missing the dummy variable for the first of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO=LAST) sets to missing the dummy variable for the last of the sorted categories, implying a zero coefficient for that category.

The specification CLASS(variable / ZERO='formatted-value') sets to missing the dummy variable for the category with a formatted value that matches 'formatted-value', implying a zero coefficient for that category. With ZERO=formatted-value-list, the first formatted value applies to the first variable in the specification, the second formatted value applies to the next variable that was not previously mentioned and so on. For example, CLASS(A A*B B*C C / ZERO='x' 'y' 'z') specifies that the reference level for A is 'x', for B is 'y', and for C is 'z'. With ZERO='formatted-value', the procedure first looks for exact matches between the formatted values and the specified value. If none are found, leading blanks are stripped from both and the values are compared again. If zero or two or more matches are found, warnings are issued.

The specifications ZERO=FIRST, ZERO=LAST, and ZERO='formatted-value' are used for reference cell models. The Intercept parameter estimate is the marginal
mean for the reference cell, and the other marginal means are obtained by adding the intercept to the dummy variable coefficients.

The specification CLASS(variable / ZERO=NONE) sets to missing none of the dummy variables. The columns of the expansion sum to a column of ones, so an implicit intercept model is fit. If you specify ZERO=NONE for more than one variable, the model is less than full rank. In the model MODEL IDENTITY(Y) = CLASS(X / ZERO=NONE), the coefficients are cell means.

The specification CLASS(variable / ZERO=SUM) sets to missing none of the dummy variables, and the coefficients for the dummy variables created from the variable sum to 0. This creates a less-than-full-rank model, but the coefficients are uniquely determined due to the sum-to-zero constraint.

In the presence of iterative transformations, hypothesis tests for ZERO=NONE and ZERO=SUM levels are not exact; they are liberal because a model with an explicit intercept is fit inside the iterations. There is no provision for adjusting the transformations while setting to 0 a parameter that is redundant given the explicit intercept and the other parameters.

**Box-Cox t-options**

The following t-options are available only with the BOXCOX transformation of the dependent variable (see the “Box-Cox Transformations” section on page 4595 and Example 75.6).

**ALPHA=\(p\)**

specifies the Box-Cox alpha for the confidence interval for the power parameter. By default, ALPHA=0.05.

**CLL=number-list**

specifies the Box-Cox convenient lambda list. When the confidence interval for the power parameter includes one of the values in this list, PROC TRANSREG reports it and can optionally use the convenient power parameter instead of the more optimal power parameter. The default is CLL=1.0 0.0 0.5 -1.0 -0.5 2.0 -2.0 3.0 -3.0. By default, a linear transformation is preferred over log, square root, inverse, inverse square root, quadratic, inverse quadratic, cubic, and inverse cubic. If you specify the CONVENIENT t-option, then PROC TRANSREG uses the first convenient power parameter in the list that is in the confidence interval. For example, if the optimal power parameter is 0.25 and 0.0 is in the confidence interval but not 1.0, then the convenient power parameter is 0.0.

**CONVENIENT CON**

specifies that a power parameter from the CLL= t-option list is to be used for the final transformation instead of the LAMBDA= t-option value if a CLL= value is in the confidence interval. See the CLL= t-option for more information on its usage.
GEOMETRICMEAN
GEO
divides the Box-Cox transformation by \( \hat{y}^{\lambda - 1} \) where \( \hat{y} \) is the geometric mean of the variable to be transformed. This form of the Box-Cox transformation essentially converts the transformation back to original units and hence allows direct comparison of the residual sums of squares for models with different power parameters.

LAMBDA=number-list
LAM=number-list
specifies a list of Box-Cox power parameters. The default is LAMBDA=-3 TO 3 BY 0.25. PROC TRANSREG tries each power parameter in the list and picks the best one. However, when the CONVENIENT t-option value is in the confidence interval. See the CLL= t-option for more information on its usage.

Other t-options
AFTER
requests that certain operations occur after the expansion. This t-option affects the NKnNOTS= t-option when the SPLINE or MSPLINE transformation is crossed with a CLASS specification. For example, if the original spline variable (1 2 3 4 5 6 7 8 9) is expanded into the three variables (1 2 3 0 0 0 0 0 0), (0 0 0 4 5 6 0 0 0), and (0 0 0 0 0 7 8 9), then, by default, NKnNOTS=1 would use the overall median of 5 as the knot for all three variables. When you specify the AFTER t-option, the knots for the three variables are 2, 5, and 8. Note that the structural zeros are ignored when the internal knot list is created, but they are not ignored for the external knots.

You can also specify the AFTER t-option with the RANK and SMOOTH transformations. The following specifications compute ranks and smooth within groups, after crossing, ignoring the structural zeros.

\[
\begin{align*}
\text{class}(x & / \text{zero}=\text{none}) & \mid \text{rank}(z / \text{after}) \\
\text{class}(x & / \text{zero}=\text{none}) & \mid \text{smooth}(z / \text{after})
\end{align*}
\]

CENTER
CEN
centers the variables before the analysis begins (in contrast to the TSTANDARD=CENTER option which centers after the analysis ends). The CENTER t-option can be used instead of running PROC STANDARD before PROC TRANSREG (see the “Centering” section on page 4675). When the KNKnOTS= t-option is specified with CENTER, the knots apply to the original variable, not to the centered variable. PROC TRANSREG will center the knots.

NAME=(variable-list)
NAM=(variable-list)
renames variables as they are used in the MODEL statement. This t-option allows a variable to be used more than once.

For example, if \( X \) is a character variable, then the following step stores both the original character variable \( X \) and a numeric variable \( XC \) that contains category numbers in the OUT= data set.
proc transreg data=a;
  model identity(y) = opscore(x / name=(xc));
  output;
  id x;
run;

With the CLASS and IDENTITY transformations, which allow interaction effects, the first name applies to the first variable in the specification, the second name applies to the next variable that was not previously mentioned, and so on. For example, IDENTITY(A A* B B* C C / NAME=(G H I)) specifies that the new name for A is G, for B is H, and for C is I. The same assignment is used for the (not useful) specification IDENTITY(A A B B C C / NAME=(G H I)). For all transforms other than CLASS and IDENTITY (all those in which interactions are not supported), repeated variables are not handled specially. For example, SPLINE(A A B B C C / NAME=(A G B H C I)) creates six variables, a copy of A named A, another copy of A named G, a copy of B named B, another copy of B named H, a copy of C named C, and another copy of C named I.

**REFLECT**

reflects the transformation

$$y = -(y - \bar{y}) + \bar{y}$$

after the iterations are completed and before the final standardization and results calculations. This _t-option_ is particularly useful with the dependent variable in a conjoint analysis. When the dependent variable consists of ranks with the most preferred combination assigned 1.0, the REFLECT _t-option_ reflects the transformation so that positive utilities mean high preference. (See Example 75.2.)

**TSTANDARD=CENTER | NOMISS | ORIGINAL | Z**

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set (see the “Centering” section on page 4675). By default, TSTANDARD=ORIGINAL. When TSTANDARD= is specified as an _a-option_ (see the description of the TSTANDARD= _a-option_ on page 4580) or an _o-option_, it determines the default standardization for all variables. When you specify TSTANDARD= as a _t-option_, it overrides the default standardization only for selected variables. You can specify a different TSTANDARD= value for each transformation. For example, to perform a redundancy analysis with standardized dependent variables, specify

```sas
model identity(y1-y4 / tstandard=z) = identity(x1-x10);
```

**Z**

centers and standardizes the variables to variance one before the analysis begins (in contrast to the TSTANDARD=Z option, which standardizes after the analysis ends). The Z _t-option_ can be used instead of running PROC STANDARD before PROC
TRANSREG (see the “Centering” section on page 4675). When the KNOTS= t-option is specified with Z, the knots apply to the original variable, not to the centered variable. PROC TRANSREG will standardize the knots.

Algorithm Options (a-options)

This section discusses the options that can appear in the PROC TRANSREG or MODEL statements as a-options. They are listed after the entire model specification and after a slash.

For example,

```plaintext
proc transreg;
  model spline(y / nknots=3)=log(x1 x2 / parameter=2)
    / nomiss maxiter=50;
  output;
run;
```

In the preceding statements, NOMISS and MAXITER= are a-options. (SPLINE and LOG are transforms, and NKNOTS= and PARAMETER= are t-options.) The statements find a spline transformation with 3 knots on Y and a base 2 logarithmic transformation on X1 and X2. The NOMISS a-option excludes all observations with missing values, and the MAXITER= a-option specifies the maximum number of iterations.

</tbody>
</table>

The following list provides details on these *a-options*.

**ADDITIVE**

**ADD**

creates an additive model by multiplying the values of each independent variable (after the TSTANDARD= standardization) by that variable’s corresponding multiple regression coefficient. This process scales the independent variables so that the predicted-values variable for the final dependent variable is simply the sum of the final independent variables. An additive model is a univariate multiple regression model. As a result, the ADDITIVE *a-option* is not valid if METHOD=CANALS, or if METHOD=REDUNDANCY or METHOD=UNIVARIATE with more than one dependent variable.

**ALPHA=** *number*

**ALP=** *number*

specifies the level of significance for all of the confidence limits. By default, ALPHA=0.05.

**CCONVERGE=** *n*

**CCO=** *n*

specifies the minimum change in the criterion being optimized (squared multiple correlation for METHOD=MORALS and METHOD=UNIVARIATE, average squared multiple correlation for METHOD=REDUNDANCY, average squared canonical correlation for METHOD=CANALS) that is required to continue iterating. By default, CCONVERGE=0.0.
CL
requests confidence limits on the parameter estimates in the displayed output.

CONVERGE=\(n\)
CON=\(n\)
specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations; that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values.

CPREFIX=\(n\)
CPR=\(n\)
specifies the number of first characters of a CLASS expansion variable’s name to use in constructing names for dummy variables. Dummy variable names are constructed from the first \(n\) characters of the CLASS expansion variable’s name and the first \(32-n\) characters of the formatted CLASS expansion variable’s value. For example, if the variable \texttt{ClassVariable} has values 1, 2, and 3, then, by default, the dummy variables are named \texttt{ClassVariable1}, \texttt{ClassVariable2}, and \texttt{ClassVariable3}. However, with CPREFIX=5, the dummy variables are named \texttt{Class1}, \texttt{Class2}, and \texttt{Class3}. When CPREFIX=0, dummy variable names are created entirely from the CLASS expansion variable’s formatted values. Valid values range from -1 to 31, where -1 indicates the default calculation and 0 to 31 are the number of prefix characters to use. The default, -1, sets \(n\) to \(32 - \min(32, \max(2, f_l))\), where \(f_l\) is the format length. When CPREFIX= is specified as an \textit{a-option} or an \textit{o-option}, it specifies the default for all CLASS variables. When you specify CPREFIX= as a \textit{t-option}, it overrides the default only for selected variables.

DETAIL
DET
reports on details of the model specification. For example, it reports the knots and coefficients for splines, reference levels for CLASS variables, Box-Cox results, and so on.

DUMMY
DUM
provides a canonical dummy variable initialization. When there are no monotonicity constraints and there is only one canonical variable in each set, PROC TRANSREG (with the DUMMY \textit{a-option}) can usually find the optimal solution in only one iteration. The initialization iteration is number 0, which is slower and uses more memory than other iterations. However, when there are no monotonicity constraints, when there is only one canonical variable in each set, and when there is enough available memory, specifying the DUMMY \textit{a-option} can greatly decrease the amount of time required to find the optimal transformations. Furthermore, by solving for the transformations directly instead of iteratively, PROC TRANSREG avoids certain nonoptimal solutions.
HISTORY
HIS

displays the iteration histories even when the NOPRINT a-option is specified.

INDIVIDUAL
IND
fits each model for each dependent variable individually. This means, for example, that when INDIVIDUAL is specified, missing values in one dependent variable will not cause that observation to be deleted for the other models with the other dependent variables. In contrast, by default, missing values in any variable in any model can cause the observation to be deleted for all models. The INDIVIDUAL option can only be specified with METHOD=MORALS.

This option also affects the order of the output. By default, the number of observations table is printed once at the beginning of the output. With INDIVIDUAL, a number of observations table appears for each model.

LPREFIX=n
LPR=n
specifies the number of first characters of a CLASS expansion variable’s label (or name if no label is specified) to use in constructing labels for dummy variables. Dummy variable labels are constructed from the first \( n \) characters of the CLASS expansion variable’s name and the first \( 127 - n \) characters of the formatted CLASS expansion variable’s value. Valid values range from -1 to 127. Values of 0 to 127 specify the number of name or label characters to use. The default is -1, which specifies that PROC TRANSREG should pick a value depending on the length of the prefix and the formatted class value. When LPREFIX= is specified as an a-option or an o-option, it determines the default for all CLASS variables. When you specify LPREFIX= as a t-option, it overrides the default only for selected variables.

MAXITER=n
MAX=n
specifies the maximum number of iterations (see the “Controlling the Number of Iterations” section on page 4601). By default, MAXITER=30. A specification of MAXITER=0 is allowed to save time when no transformations are requested.

METHOD=CANALS | MORALS | REDUNDANCY | UNIVARIATE
MET=CAN | MOR | RED | UNI
specifies the iterative algorithm. By default, METHOD=UNIVARIATE, unless you specify options that cannot be handled by the UNIVARIATE algorithm. Specifically, the default is METHOD=MORALS for the following situations:

- if you specify LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, or SSPLINE transformations for the independent variables
- if you specify the ADDITIVE a-option with more than one dependent variable
- if you specify the IAPPROXIMATIONS o-option
CANALS specifies canonical correlation with alternating least squares. This jointly transforms all dependent and independent variables to maximize the average of the first $n$ squared canonical correlations, where $n$ is the value of the NCAN= a-option.

MORALS specifies multiple optimal regression with alternating least squares. This transforms each dependent variable, along with the set of independent variables, to maximize the squared multiple correlation.

REDUNDANCY jointly transforms all dependent and independent variables to maximize the average of the squared multiple correlations (see the “Redundancy Analysis” section on page 4606).

UNIVARIATE transforms each dependent variable to maximize the squared multiple correlation, while the independent variables are not transformed.

MONOTONE=two-letters

MON=two-letters specifies the first and last special missing value in the list of those special missing values to be estimated using within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The two-letters value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of .-, .A through .C, and .G through .Z. For details, see the “Missing Values” section on page 4599.

NCAN=n

NCA=n specifies the number of canonical variables to use in the METHOD=CANALS algorithm. By default, NCAN=1. The value of the NCAN= a-option must be $\geq 1$.

When canonical coefficients and coordinates are included in the OUT= data set, the NCAN= a-option also controls the number of rows of the canonical coefficient matrices in the data set. If you specify an NCAN= value larger than the minimum of the number of dependent variables and the number of independent variables, PROC TRANSREG displays a warning and sets the NCAN= a-option to the maximum allowable value.

NOINT

NOI omits the intercept from the OUT= data set and suppresses centering of data. The NOINT a-option is not allowed with iterative transformations since there is no provision for optimal scaling without an intercept. The NOINT a-option is allowed only when there is no implicit intercept and when all of the data in a BY group absolutely will not change during the iterations.
NOMISS
NOM
excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS a-option, PROC TRANSREG simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error. For details, see the “Missing Values” section on page 4599.

Casewise deletion of observations with missing values occurs when the NOMISS a-option is specified, when there are missing values in expansions, when there are missing values in METHOD=UNIVARIATE independent variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as supplementary or passive observations.

See the “Passive Observations” section on page 4605 for more information on excluded observations.

NOPRINT
NOP
suppresses the display of all output unless you specify the HISTORY a-option. The NOPRINT a-option without the HISTORY a-option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

NOZEROCONSTANT
NOZERO
NOZ
specifies that constant variables are expected and should not be zeroed. By default, constant variables are zeroed. This option is useful when PROC TRANSREG is used to code experimental designs for discrete choice models (see the “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” section on page 4660). When these designs are very large, it may be more efficient to use the DESIGN=n option. It may be that attributes are constant within a block of n observations, so you need to specify the NOZEROCONSTANT option to get the correct results. You can specify this option in the PROC TRANSREG, MODEL, and OUTPUT statements.

ORDER=DATA | FREQ | FORMATTED | INTERNAL
ORD=DAT | FRE | FOR | INT
specifies the order in which the CLASS variable levels are to be reported. The default is ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When ORDER= is specified as an a-option or an o-option, it determines the default ordering for all CLASS variables. When you specify ORDER= as a t-option, it overrides the default ordering only for selected variables.

DATA sorts by order of appearance in the input data set.
FORMATTED sorts by formatted value.
FREQ sorts by descending frequency count; levels with the most observations appear first.

INTERNAL sorts by unformatted value.

**REFERENCE=NONE | MISSING | ZERO**

**REF=NON | MIS | ZER**
specifies how reference levels of CLASS variables are to be treated. The options are REFERENCE=NONE, the default, in which reference levels are suppressed; REFERENCE=MISSING, in which reference levels are displayed and output with missing values; and REFERENCE=ZERO, in which reference levels are displayed and output with zeros. The REFERENCE= option can be specified in the PROC TRANSREG, MODEL, or OUTPUT statement, and it can be independently specified for the OUT= data set and the displayed output. When you specify it in only one statement, it sets the option for both the displayed output and the OUT= data set.

**REITERATE**

**REI**
enables the TRANSREG procedure to use previous transformations as starting points. The REITERATE a-option affects only variables that are iteratively transformed (specified as LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE). For iterative transformations, the REITERATE a-option requests a search in the input data set for a variable that consists of the value of the TDPREFIX= or TIPREFIX= o-option followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the section “Using the REITERATE Algorithm Option” on page 4602.

**SEPARATORS=’string-1’<’string-2’**

**SEP=’string-1’<’string-2’**
specifies separators for creating CLASS expansion variable labels. By default, SEPARATORS=’ ’ ‘ * ’ (“blank” and “blank asterisk blank”). The first value is used to separate variable names and values in interactions. The second value is used to separate interaction components. For example, the label for the dummy variable for the A=1 and B=2 cell is, by default, ’A 1 B 2’. If SEPARATORS=’= ’ ’x’ is specified, then the label is ’A=1xB=2’. When SEPARATORS= is specified as an a-option or an o-option, it determines the default separators for all CLASS variables. When you specify SEPARATORS= as a t-option, it overrides the default only for selected variables.

**SHORT**

**SHO**
suppresses the iteration histories.

**SINGULAR=n**

**SIN=n**
specifies the largest value within rounding error of zero. By default, SINGULAR=1E−12. The TRANSREG procedure uses the value of the SINGULAR a-option for checking $1 - R^2$ when constructing full-rank ma-
trices of predictor variables, checking denominators before dividing, and so on. PROC TRANSREG computes the regression coefficients by sweeping with rational pivoting.

**SS2**

produces a regression table based on Type II sums of squares. Tests of the contribution of each transformation to the overall model are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the SS2 a-option, the TEST a-option is implied. See the section “Hypothesis Tests” on page 4615. You can suppress the variable labels in the regression tables by specifying the NOLABEL option in the OPTIONS statement.

**TEST**

generates an ANOVA table. PROC TRANSREG tests the null hypothesis that the vector of scoring coefficients for all of the transformations is zero. See the section “Hypothesis Tests” on page 4615.

**TSTANDARD=** CENTER | NOMISS | ORIGINAL | Z

specifies the standardization of the transformed variables for the hypothesis tests and in the OUT= data set. By default, TSTANDARD=ORIGINAL. When TSTANDARD= is specified as an a-option or an o-option, it determines the default standardization for all variables. When you specify TSTANDARD= as a t-option, it overrides the default standardization only for selected variables.

CENTER centers the output variables to mean zero, but the variances are the same as the variances of the input variables.

NOMISS sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.

ORIGINAL sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.

Z standardizes the variables to mean zero, variance one.

The final standardization is affected by other options. If you also specify the ADDITIVE a-option, the TSTANDARD= option specifies an intermediate step in computing the final means and variances. The final independent variables, along with their means and standard deviations, are scaled by the regression coefficients, creating an additive model with all coefficients equal to one.
For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the ORIGINAL nonoptimal t-option in the MODEL statement. For example, if a variable \( X \) with no missing values is specified as LOG, then, by default, the final transformation of \( X \) is simply \( \log(X) \), not \( \log(X) \) standardized to the mean of \( X \) and variance of \( X \).

**TYPE='text'|name**

**TYP='text'|name**

specifies the valid value for the _TYPE_ variable in the input data set. If PROC TRANSREG finds an input _TYPE_ variable, it uses only observations with a _TYPE_ value that matches the TYPE= value. This enables a PROC TRANSREG OUT= data set containing coefficients to be used as input to PROC TRANSREG without requiring a WHERE statement to exclude the coefficients. If a _TYPE_ variable is not in the data set, all observations are used. The default is TYPE='SCORE', so if you do not specify the TYPE= a-option, only observations with _TYPE_='SCORE' are used. Do not confuse this option with the data set TYPE= option. The DATA= data set must be an ordinary SAS data set.

PROC TRANSREG displays a note when it reads observations with blank values of _TYPE_, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank _TYPE_ values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their _TYPE_ value is blank.

**UNTIE=two-letters**

**UNT=two-letters**

specifies the first and last special missing value in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The two-letters value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the “Missing Values” section on page 4599 and the “Optimal Scaling” section on page 4609.

**UTILITIES**

**UTI**

produces a table of the part-worth utilities from a conjoint analysis. Utilities, their standard errors, and the relative importance of each factor are displayed and output to the OUTTEST= data set when you specify the OUTTEST= option. When you specify the UTILITIES a-option, the TEST a-option is implied. Refer to SAS Technical Report R-109, Conjoint Analysis Examples, for more information on conjoint analysis.
The OUTPUT statement creates a new SAS data set that contains coefficients, marginal means, and information on original and transformed variables. The information on original and transformed variables composes the score partition of the data set; observations have _TYPE_='SCORE'. The coefficients and marginal means compose the coefficient partition of the data set; observations have _TYPE_='M COEFFI' or _TYPE_='MEAN'. Other values of _TYPE_ are possible; for details, see “_TYPE_ and _NAME_ Variables” later in this chapter. For details on data set structure, see the “Output Data Set” section on page 4617.

To specify the data set, use the OUT= specification.

OUT=SAS-data-set specifies the output data set for the data, transformed data, predicted values, residuals, scores, coefficients, and so on. When you use an OUTPUT statement but do not use the OUT= specification, PROC TRANSREG creates a data set and uses the DATA step convention. If you want to create a permanent SAS data set, you must specify a two-level name (refer to “SAS Files” in SAS Language Reference: Concepts and “Introduction to DATA Step Processing” in the SAS Procedures Guide for details).

To control the contents of the data set and variable names, use one or more of the o-options. You can also specify these options in the PROC TRANSREG statement.

Output Options (o-options)

The following table provides a summary of options in the OUTPUT statement. These options include the OUT= option and all of the o-options.

<table>
<thead>

</table>
For the coefficients partition, the COEFFICIENTS, COORDINATES, and MEANS o-options provide the coefficients that are appropriate for your model. For more explicit control of the coefficient partition, use the options that control details and prefixes.

The following list provides details on these options.

**ADPREFIX=**name
**ADP=**name
specifies a prefix for naming the dependent variable predicted values. The default is ADPREFIX=P when you specify the PREDICTED o-option; otherwise, it is ADPREFIX=A. Specifying the ADPREFIX= o-option also implies the PREDICTED o-option, and the ADPREFIX= o-option is the same as the PPREFIX= o-option.

**AIPREFIX=**name
**AIP=**name
specifies a prefix for naming the independent variable approximations. The default is AIPREFIX=A. Specifying the AIPREFIX= o-option also implies the IAPPROXIMATIONS o-option.

**APPROXIMATIONS**
**AP**
**APP**
is equivalent to specifying both the DAPPROXIMATIONS and the IAPPROXIMATIONS o-options. If METHOD=UNIVARIATE, then the APPROXIMATIONS o-option implies only the DAPPROXIMATIONS o-option.

**CANONICAL**
**CAN**
outputs canonical variables to the OUT= data set. When METHOD=CANALS, the CANONICAL o-option is implied. The CDPREFIX= o-option specifies a prefix for naming the dependent canonical variables (default Cand), and the CIPREFIX= o-option specifies a prefix for naming the independent canonical variables (default Cani).

**CCC**
outputs canonical correlation coefficients to the OUT= data set.

**CDPREFIX=**name
**CDP=**name
provides a prefix for naming the canonical dependent variables. The default is CDPREFIX=Cand. Specifying the CDPREFIX= o-option also implies the CANONICAL o-option.

**CEC**
outputs canonical elliptical point model coordinates to the OUT= data set.

**CILPREFIX=**name
**CIL=**name
specifies a prefix for naming the conservative-individual-lower confidence limits. The default prefix is CIL. Specifying the CILPREFIX= o-option also implies the CLI o-option.
CIPREFIX=\textit{name}
\textbf{CIP=} \textit{name}

provides a prefix for naming the canonical independent variables. The default is \text{CIPREFIX=} \text{Cani}. Specifying the \text{CIPREFIX=} \textit{o-option} also implies the \text{CANONICAL} \textit{o-option}.

CIUPREFIX=\textit{name}
\textbf{CIU=} \textit{name}

specifies a prefix for naming the conservative-individual-upper confidence limits. The default prefix is \text{CIU}. Specifying the \text{CIUPREFIX=} \textit{o-option} also implies the \text{CLI} \textit{o-option}.

\textbf{CLI}

outputs individual confidence limits to the \text{OUT=} data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following \textit{o-options}: \text{LILPREFIX=} (default \text{LIL} for liberal individual lower), \text{CILPREFIX=} (default \text{CIL} for conservative individual lower), \text{LIUPREFIX=} (default \text{LIU} for liberal individual upper), and \text{CIUPREFIX=} (default \text{CIU} for conservative individual upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

\textbf{CLM}

outputs mean confidence limits to the \text{OUT=} data set. The names of the confidence limits variables are constructed from the original dependent variable names and the prefixes specified in the following \textit{o-options}: \text{LMLPREFIX=} (default \text{LML} for liberal mean lower), \text{CMLPREFIX=} (default \text{CML} for conservative mean lower), \text{LMUPREFIX=} (default \text{LMU} for liberal mean upper), and \text{CMUPREFIX=} (default \text{CMU} for conservative mean upper). When there are no monotonicity constraints, the liberal and conservative limits are the same.

CMLPREFIX=\textit{name}
\textbf{CML=} \textit{name}

specifies a prefix for naming the conservative-mean-lower confidence limits. The default prefix is \text{CML}. Specifying the \text{CMLPREFIX=} \textit{o-option} also implies the \text{CLM} \textit{o-option}.

CMUPREFIX=\textit{name}
\textbf{CMU=} \textit{name}

specifies a prefix for naming the conservative-mean-upper confidence limits. The default prefix is \text{CMU}. Specifying the \text{CMUPREFIX=} \textit{o-option} also implies the \text{CLM} \textit{o-option}.

\textbf{COEFFICIENTS}

\textbf{COE}

outputs either multiple regression coefficients or raw canonical coefficients to the \text{OUT=} data set. If you specify \text{METHOD=} \text{CANALS} (in the \text{MODEL} or \text{PROC TRANSREG} statement), then the \text{COEFFICIENTS} \textit{o-option} outputs the first \(n\) canonical variables, where \(n\) is the value of the \text{NCAN=} \textit{a-option} (specified in the \text{MODEL} or \text{PROC TRANSREG} statement). Otherwise, the \text{COEFFICIENTS} \textit{o-option} includes multiple regression coefficients in the \text{OUT=} data set. In ad-
dition, when you specify the CLASS expansion for any independent variable, the COEFFICIENTS o-option also outputs marginal means.

COORDINATES
COO
outputs either ideal point or vector model coordinates for preference mapping to the OUT= data set. When METHOD=CANALS, these coordinates are computed from canonical coefficients; otherwise, the coordinates are computed from multiple regression coefficients. For details, see the “Point Models” section on page 4605.

CPC
outputs canonical point model coordinates to the OUT= data set.

CQC
outputs canonical quadratic point model coordinates to the OUT= data set.

DAPPROXIMATIONS
DAP
outputs the approximations of the transformed dependent variables to the OUT= data set. These are the target values for the optimal transformations. With METHOD=UNIVARIATE and METHOD=MORALS, the dependent variable approximations are the ordinary predicted values from the linear model. The names of the approximation variables are constructed from the ADPREFIX= o-option (default A) and the original dependent variable names. For ordinary predicted values, use the PREDICTED o-option instead of the DAPPROXIMATIONS o-option, since the PREDICTED o-option uses a more relevant prefix (“P” instead of “A”) and a more relevant variable label suffix (“Predicted Values” instead of “Approximations”).

DESIGN<<=n>
DES<<=n>
specifies that your primary goal is design matrix coding, not analysis. Specifying the DESIGN o-option makes the procedure run faster. The DESIGN o-option sets the default method to UNIVARIATE and the default MAXITER= value to zero. It suppresses computing the regression coefficients, unless they are needed for some other option. Furthermore, when the DESIGN o-option is specified, the MODEL statement is not required to have an equal sign. When no MODEL statement equal sign is specified, all variables are considered independent variables, all options that require dependent variables are ignored, and the IREPLACE o-option is implied.

You can use DESIGN=n for coding very large data sets, where n is the number of observations to code at one time. For example, to code a data set with a large number of observations, you can specify DESIGN=100 or DESIGN=1000 to process the data set in blocks of 100 or 1000 observations. If you specify the DESIGN o-option rather than DESIGN=n, PROC TRANSREG tries to process all observations at once, which will not work with very large data sets. Specify the NOZEROCONSTANT a-option with DESIGN=n to ensure that constant variables within blocks are not zeroed. See the section “Using the DESIGN Output Option” on page 4654 and the section “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 4660.
DEPENDENT=name
DEP=name
specifies the untransformed dependent variable for OUT= data sets with METHOD=MORALS when there is more than one dependent variable. The default is DEPENDENT=_DEPEND_.

DREPLACE
DRE
replaces the original dependent variables with the transformed dependent variables in the OUT= data set. The names of the transformed variables in the OUT= data set correspond to the names of the original dependent variables in the input data set. By default, both the original dependent variables and transformed dependent variables (with names constructed from the TDPREFIX= (default T) o-option and the original dependent variable names) are included in the OUT= data set.

IAPPROXIMATIONS
IAP
outputs the approximations of the transformed independent variables to the OUT= data set. These are the target values for the optimal transformations. The names of the approximation variables are constructed from the AIPREFIX= o-option (default A) and the original independent variable names. Specifying the AIPREFIX= o-option also implies the IAPPROXIMATIONS o-option. The IAPPROXIMATIONS o-option is not valid when METHOD=UNIVARIATE.

IREPLACE
IRE
replaces the original independent variables with the transformed independent variables in the OUT= data set. The names of the transformed variables in the OUT= data set correspond to the names of the original independent variables in the input data set. By default, both the original independent variables and transformed independent variables (with names constructed from the TIPREFIX= (default T) and the original independent variable names) are included in the OUT= data set.

LEVERAGE<=name>
LEV<=name>
creates a variable with the specified name in the OUT= data set that contains leverages. Specifying the LEVERAGE o-option is equivalent to specifying LEVERAGE=Leverage.

LILPREFIX=name
LIL=name
specifies a prefix for naming the liberal-individual-lower confidence limits. The default prefix is LIL. Specifying the LILPREFIX= o-option also implies the CLI o-option.

LIUPREFIX=name
LIU=name
specifies a prefix for naming the liberal-individual-upper confidence limits. The default prefix is LIU. Specifying the LIUPREFIX= o-option also implies the CLI o-option.
Chapter 75. The TRANSREG Procedure

**LMLPREFIX=** name
**LML=** name
specifies a prefix for naming the liberal-mean-lower confidence limits. The default prefix is LML. Specifying the LMLPREFIX= o-option also implies the CLM o-option.

**LMUPREFIX=** name
**LMU=** name
specifies a prefix for naming the liberal-mean-upper confidence limits. The default prefix is LMU. Specifying the LMUPREFIX= o-option also implies the CLM o-option.

**MACRO**(keyword=name...) **MAC**(keyword=name...)
creates macro variables. Most of the options available within the MACRO o-option are rarely needed. By default, the TRANSREG procedure creates a macro variable named _TRGIND with a complete list of independent variables created by the procedure. When the TRANSREG procedure is being used for design matrix creation prior to running a procedure without a CLASS statement, this macro provides a convenient way to use the results from PROC TRANSREG. For example, a PROC LOGISTIC step that uses a design matrix coded by PROC TRANSREG could use the following MODEL statement:

```plaintext
model y=&_trgind;
```

The TRANSREG procedure, also by default, creates a macro variable named _TRGINDN, which contains the number of variables in the _TRGIND list. This macro variable could be used in an ARRAY statement as follows:

```plaintext
array indvars[&_trgindn] &_trgind;
```

See the section “Using the DESIGN Output Option” on page 4654 and the section “Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO” on page 4660 for examples of using the default macro variables.

The available keywords are as follows.

**DN=** name specifies the name of a macro variable that contains the number of dependent variables. By default, a macro variable named _TRGDEPN is created. This is the number of variables in the DL= list and the number of macro variables created by the DV= and DE= specifications.

**IN=** name specifies the name of a macro variable that contains the number of independent variables. By default, a macro variable named _TRGINDN is created. This is the number of variables in the IL= list and the number of macro variables created by the IV= and IE= specifications.
DL= name specifies the name of a macro variable that contains the list of the dependent variables. By default, a macro variable named _TRGDEP is created. These are the variable names of the final transformed variables in the OUT= data set. For example, if there are three dependent variables, Y1–Y3, then _TRGDEP contains, by default, TY1 TY2 TY3 (or Y1 Y2 Y3 if you specify the REPLACE o-option).

IL= name specifies the name of a macro variable that contains the list of the independent variables. By default, a macro variable named _TRGIND is created. These are the variable names of the final transformed variables in the OUT= data set. For example, if there are three independent variables, X1–X3, then _TRGIND contains, by default, TX1 TX2 TX3 (or X1 X2 X3 if you specify the REPLACE o-option).

DV= prefix specifies a prefix for creating a list of macro variables, each of which contains one dependent variable name. For example, if there are three dependent variables, Y1–Y3, and you specify MACRO(DV=DEP), then three macro variables, DEP1, DEP2, and DEP3, are created, containing TY1, TY2, and TY3, respectively (or Y1, Y2, and Y3 if you specify the REPLACE o-option). By default, no list is created.

IV= prefix specifies a prefix for creating a list of macro variables, each of which contains one independent variable name. For example, if there are three independent variables, X1–X3, and you specify MACRO(IV=IND), then three macro variables, IND1, IND2, and IND3, are created, containing TX1, TX2, and TX3, respectively (or X1, X2, and X3 if you specify the REPLACE o-option). By default, no list is created.

DE= prefix specifies a prefix for creating a list of macro variables, each of which contains one dependent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify MACRO(DE=D), then a macro variable D1 is created for IDENTITY(Y). The D1 macro variable is shown next, wrapped onto two lines.

```
4          TY
IDENTITY   Y
```

The first part is the number of parts (4), the second part is the transformed variable name, the third part is the transformation, and the last part is the input variable name. By default, no list is created.

IE= prefix specifies a prefix for creating a list of macro variables, each of which contains one independent variable effect. This list shows the origin of each model term. Each effect consists of two or more parts, and each part consists of a value in 32 columns followed by a blank. For example, if you specify MACRO(IE=I), then three
macro variables, \( I_1, I_2, \) and \( I_3 \), are created for \( \text{CLASS}(X_1 \mid X_2) \) when both \( X_1 \) and \( X_2 \) have values of 1 and 2. These macro variables are shown next, but with extra white space removed.

\[
\begin{align*}
5 & \quad Tx11 \quad \text{CLASS} \quad x_1 \quad 1 \\
5 & \quad Tx21 \quad \text{CLASS} \quad x_2 \quad 1 \\
8 & \quad Tx11x21 \quad \text{CLASS} \quad x_1 \quad 1 \quad \text{CLASS} \quad x_2 \quad 1
\end{align*}
\]

For \( \text{CLASS} \) variables, the formatted level appears after the variable name. The first two effects are the main effects, and the last is the interaction term. By default, no list is created.

**MEANS**
**MEA**

outputs marginal means for \( \text{CLASS} \) variable expansions to the OUT= data set.

**MEC**

outputs multiple regression elliptical point model coordinates to the OUT= data set.

**MPC**

outputs multiple regression point model coordinates to the OUT= data set.

**MQC**

outputs multiple regression quadratic point model coordinates to the OUT= data set.

**MRC**

outputs multiple regression coefficients to the OUT= data set.

**MREDUNDANCY**
**MRE**

outputs multiple redundancy analysis coefficients to the OUT= data set.

**NORESTOREMISSING**
**NORESTORE**
**NOR**

specifies that missing values should not be restored when the OUT= data set is created. By default, the coded \( \text{CLASS} \) variable contains a row of missing values for observations in which the \( \text{CLASS} \) variable is missing. When you specify the NORESTOREMISSING o-option, these observations contain a row of zeros instead. This is useful when the TRANSREG procedure is used to code experimental designs for discrete choice models and there is a constant alternative indicated by a missing value.

**NOSCORES**
**NOS**

excludes original variables, transformed variables, predicted values, residuals, and scores from the OUT= data set. You can use the NOSCORES o-option with various other options to create an OUT= data set that contains only a coefficient partition (for example, a data set consisting entirely of coefficients and coordinates).
OUTPUT Statement ♦ 4591

PREDICTED
PRE
P
outputs predicted values, which for METHOD=UNIVARIATE and
METHOD=MORALS are the ordinary predicted values from the linear model, to
the OUT= data set. The names of the predicted values’ variables are constructed
from the PPREFIX= o-option (default P) and the original dependent variable names.
Specifying the PPREFIX= o-option also implies the PREDICTED o-option.

PPREFIX= name
PDPREFIX= name
PDP= name
specifies a prefix for naming the dependent variable predicted values. The de-
default is PPREFIX=P when you specify the PREDICTED o-option; otherwise, it is
PPREFIX=A. Specifying the PPREFIX= o-option also implies the PREDICTED o-
option, and the PPREFIX= o-option is the same as the ADPREFIX= o-option.

RDPREFIX= name
RDP= name
specifies a prefix for naming the residual (dependent) variables to the OUT= data set.
The default is RDPREFIX=R. Specifying the RDPREFIX= o-option also implies the
RESIDUALS o-option.

REDUNDANCY <=STANDARDIZE | UNSTANDARDIZE>
RED<=STA | UN>
outputs redundancy variables to the OUT= data set, either standardized or un-
standardized. Specifying the REDUNDANCY o-option is the same as specifying
REDUNDANCY=STANDARDIZE. The results of the REDUNDANCY o-option
depends on the TSTANDARD= option. You must specify TSTANDARD=Z to get results based on standardized data. The TSTANDARD= option con-
trols how the data that go into the redundancy analysis are scaled, and
REDUNDANCY=STANDARDIZE|UNSTANDARDIZE controls how the re-
dundancy variables are scaled. The REDUNDANCY o-option is implied by
METHOD=REDUNDANCY. The RPREFIX= o-option specifies a prefix (default Red) for naming the redundancy variables.

REFERENCE=NONE | MISSING | ZERO
REF=NON | MIS | ZER
specifies how reference levels of CLASS variables are to be treated. The options
are REFERENCE=NONE, the default, in which reference levels are suppressed;
REFERENCE=MISSING, in which reference levels are displayed and output with
missing values; and REFERENCE=ZERO, in which reference levels are displayed
and output with zeros. The REFERENCE= option can be specified in the PROC
TRANSREG, MODEL, or OUTPUT statement, and it can be independently speci-
fied for the OUT= data set and the displayed output. When you specify it in only one
statement, it sets the option for both the displayed output and the OUT= data set.
REPLACE
REP
is equivalent to specifying both the DREPLACE and the IREPLACE o-options.

RESIDUALS
RES
R
outputs the differences between the transformed dependent variables and their predicted values. The names of the residual variables are constructed from the RDPREFIX= o-option (default $R$) and the original dependent variable names.

RPREFIX=name
RPR=name
provides a prefix for naming the redundancy variables. The default is RPREFIX=Red. Specifying the RPREFIX= o-option also implies the REDUNDANCY o-option.

TDPREFIX=name
TDP=name
specifies a prefix for naming the transformed dependent variables. By default, TDPREFIX=T. The TDPREFIX= o-option is ignored when you specify the DREPLACE o-option.

TIPREFIX=name
TIP=name
specifies a prefix for naming the transformed independent variables. By default, TIPREFIX=T. The TIPREFIX= o-option is ignored when you specify the IREPLACE o-option.

WEIGHT Statement

WEIGHT variable ;

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.

Details

Model Statement Usage

MODEL < transform(dependents < / t-options >)  
    < transform(dependents < / t-options >)... = >  
    transform(independents < / t-options >)  
    < transform(independents < / t-options >)... > < / a-options > ;

Here are some examples of model statements:

- linear regression
model identity(y) = identity(x);
• a linear model with a nonlinear regression function
  model identity(y) = spline(x / nknots=5);
• multiple regression
  model identity(y) = identity(x1-x5);
• multiple regression with nonlinear transformations
  model spline(y / nknots=3) = spline(x1-x5 / nknots=3);
• multiple regression with nonlinear but monotone transformations
  model mspline(y / nknots=3) = mspline(x1-x5 / nknots=3);
• multivariate multiple regression
  model identity(y1-y4) = identity(x1-x5);
• canonical correlation
  model identity(y1-y4) = identity(x1-x5) / method=canals;
• redundancy analysis
  model identity(y1-y4) = identity(x1-x5) / method=redundancy;
• preference mapping, vector model (Carroll 1972)
  model identity(Attrib1-Attrib3) = identity(Dim1-Dim2);
• preference mapping, ideal point model (Carroll 1972)
  model identity(Attrib1-Attrib3) = point(Dim1-Dim2);
• preference mapping, ideal point model, elliptical (Carroll 1972)
  model identity(Attrib1-Attrib3) = epoint(Dim1-Dim2);
• preference mapping, ideal point model, quadratic (Carroll 1972)
  model identity(Attrib1-Attrib3) = qpoint(Dim1-Dim2);
• metric conjoint analysis
  model identity(Subj1-Subj50) = class(a b c d e f / zero=sum);
• nonmetric conjoint analysis
  model monotone(Subj1-Subj50) = class(a b c d e f / zero=sum);
• main effects, two-way interaction
  model identity(y) = class(a|b);
• less-than-full-rank model—main effects and two-way interaction are constrained to sum to zero
  model identity(y) = class(a|b / zero=sum);
• main effects and all two-way interactions
  model identity(y) = class(a|b|c@2);
• main effects and all two- and three-way interactions
  model identity(y) = class(a|b|c);
• main effects and just B*C two-way interaction
  model identity(y) = class(a b c b*c);
• seven main effects, three two-way interactions
  model identity(y) = class(a b c d e f g a*b a*c a*d);
• deviations-from-means (effects or (1, 0, □ 1)) coding, with an A reference level of ’1’ and a B reference level of ’2’
  model identity(y) = class(a|b / deviations zero=’1’ ‘2’);
• cell-means coding (implicit intercept)
  model identity(y) = class(a*b / zero=none);
• reference cell model
  model identity(y) = class(a|b / zero=’1’ ‘1’);
• reference line with change in line parameters
  model identity(y) = class(a) | identity(x);
• reference curve with change in curve parameters
  model identity(y) = class(a) | spline(x);
• separate curves and intercepts
  model identity(y) = class(a / zero=none) | spline(x);
• quantitative effects with interaction
  model identity(y) = identity(x1 | x2);
• separate quantitative effects with interaction within each cell
  model identity(y) = class(a * b / zero=none) | identity(x1 | x2);
The Box-Cox (1964) transformation has the form

\[
\frac{(y^\lambda - 1)}{\lambda} \quad \lambda \neq 0 \\
\log(y) \quad \lambda = 0
\]

This family of transformations of the positive dependent variable \( y \) is controlled by the parameter \( \lambda \). Transformations linearly related to square root, inverse, quadratic, cubic, and so on are all special cases. The limit as \( \lambda \) approaches 0 is the log transformation. More generally, Box-Cox transformations of the following form can be fit:

\[
\frac{((y + c)^\lambda - 1)}{(\lambda g)} \quad \lambda \neq 0 \\
\log(y + c)/g \quad \lambda = 0
\]

By default, \( c = 0 \). The parameter \( c \) can be used to rescale \( y \) so that it is strictly positive. By default, \( g = 1 \). Alternatively, \( g \) can be \( \hat{y}^{\lambda - 1} \) where \( \hat{y} \) is the geometric mean of \( y \).

The BOXCOX transformation in PROC TRANSREG can be used to perform a Box-Cox transformation of the dependent variable. You can specify a list of power parameters using the LAMBDA= transformation option. By default, LAMBDA=-3 TO 3 BY 0.25. The procedure chooses the optimal power parameter using a maximum likelihood criterion (Draper and Smith 1981, pp. 225-226). You can specify the PARAMETER=c transformation option when you want to shift the values of \( y \), usually to avoid negatives. To divide by \( \hat{y}^{\lambda - 1} \), specify the GEOMETRICMEAN transformation option.

Here are some examples of usage of the LAMBDA= option:

```plaintext
model BoxCox(y / lambda=0) = identity(x1-x5);
model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);
model BoxCox(y) = identity(x1-x5);
```

In the first example

```plaintext
model BoxCox(y / lambda=0) = identity(x1-x5);
```

LAMBDA=0 specifies a Box-Cox transformation with a power parameter of 0. Since a single value of 0 was specified for LAMBDA=, there is no difference between the following models:

```plaintext
model BoxCox(y / lambda=0) = identity(x1-x5);
model log(y) = identity(x1-x5);
```

In the second example
Chapter 75. The TRANSREG Procedure

model BoxCox(y / lambda=-2 to 2 by 0.1) = identity(x1-x5);

there is a list of power parameters specified. This tells PROC TRANSREG to find a Box-Cox transformation before the usual iterations begin. PROC TRANSREG tries each power parameter in the list and picks the best transformation. A maximum likelihood approach (Draper and Smith 1981, pp. 225-226) is used. Note that this is quite different from TRANSREG’s usual approach of iteratively finding optimal transformations. It is analogous to SMOOTH, RANK, and the other nonoptimal transformations that are performed before the iterations begin.

In the third example

model BoxCox(y) = identity(x1-x5);

the default list of -3 TO 3 BY 0.25 is used.

The procedure prints the optimal power parameter, a confidence interval on the power parameter (using the ALPHA= transformation option), a “convenient” power parameter (selected from the CLL= option list), and the log likelihood for each power parameter tried (see Example 75.6).

Smoothing Splines

You can use PROC TRANSREG to output to a SAS data set the same smoothing splines that the GPLOT procedure creates. The SMOOTH transformation is a noniterative transformation for smoothing splines. The smoothing parameter can be specified with either the SM= or the PARAMETER=o-option. The independent variable transformation (Tx in this case) contains the results. The GPLOT request y*x=2 with I=SM50 creates the same curve as Tx*x.

title 'Smoothing Splines';

data x;
    do x = 1 to 100 by 2;
        do rep = 1 to 3;
            y = log(x) + sin(x / 10) + normal(7);
            output;
        end;
    end;
run;

proc transreg;
    model identity(y) = smooth(x / sm=50);
    output;
run;

%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
proc gplot;
    axis1 minor=none label=(angle=90 rotate=0);
    axis2 minor=none;
When you cross a SMOOTH variable with a CLASS variable, specify ZERO=NONE with the CLASS expansion and the AFTER t-option with the SMOOTH transformation so that separate functions are found within each group.

```
data x;
   do x = 1 to 100;
      group = 1;
      do rep = 1 to 3;
         y = log(x) + sin(x / 10) + normal(7);
         output;
      end;
      group = 2;
      do rep = 1 to 3;
         y = -log(x) + cos(x / 10) + normal(7);
         output;
      end;
   end;
run;
```
proc transreg;
  model identity(y) = class(group / zero=none) |
  smooth(x / after sm=50);
  output out=curves;
run;

data curves2;
  set curves;
  if group1 = 0 then tgroup1x = .;
  if group2 = 0 then tgroup2x = .;
run;

%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
proc gplot;
  axis1 minor=none label=(angle=90 rotate=0);
  axis2 minor=none;
  plot y*x=1 tgroup1x*x=2 tgroup2x*x=2 / &opts overlay;
  symbol1 color=blue v=star i=none;
  symbol2 color=yellow v=none i=join;
run; quit;

Figure 75.6. Smoothing Spline Example 2

The SMOOTH transformation is valid only with independent variables; typically, it is used in models with a single independent and a single dependent variable. When there are multiple independent variables designated as SMOOTH, the TRANSREG procedure tries to smooth the $i$th independent variable using the $i$th dependent variable as a target. When there are more independent variables than dependent variables, the last dependent variable is reused as often as is necessary. For example, for the model
model identity(y1-y3) = smooth(x1-x5);

smoothing is based on the pairs (y1, x1), (y2, x2), (y3, x3), (y3, x4), and (y3, x5).
The SMOOTH transformation is a noniterative transformation; smoothing occurs once per variable before the iterations begin. In contrast, SSPLINE provides an iterative smoothing spline transformation. It does not generally minimize squared error; hence, divergence is possible with SSPLINE.

**Missing Values**

PROC TRANSREG can estimate missing values, with or without category or monotonicity constraints, so that the regression model fit is optimized. Several approaches to missing data handling are provided. All observations with missing values in IDENTITY, CLASS, POINT, EPOINT, QPOINT, SMOOTH, PSPLINE, and BSPLINE variables are excluded from the analysis. When METHOD=UNIVARIATE (specified in the PROC TRANSREG or MODEL statement), observations with missing values in any of the independent variables are excluded from the analysis. When you specify the NOMISS a-option, observations with missing values in the other analysis variables are excluded. Otherwise, missing data are estimated, using variable means as initial estimates.

You can specify the LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, SSPLINE, LOG, LOGIT, POWER, ARSIN, BOXCOX, RANK, and EXP transformations in any combination with nonmissing values, ordinary missing values, and special missing values, as long as the nonmissing values in each variable have positive variance. No category or order restrictions are placed on the estimates of ordinary missing values. You can force missing value estimates within a variable to be identical by using special missing values (refer to “DATA Step Processing” in SAS Language Reference: Concepts). You can specify up to 27 categories of missing values, in which within-category estimates must be the same, by coding the missing values using _, and .A through .Z.

You can also specify an ordering of some missing value estimates. You can use the MONOTONE= a-option in the PROC TRANSREG or MODEL statement to indicate a range of special missing values (a subset of the list from .A to .Z) with estimates that must be weakly ordered within each variable in which they appear. For example, if MONOTONE=AI, the nine classes, .A, .B, . . . , .I, are monotonically scored and optimally scaled just as MONOTONE transformation values are scored. In this case, category but not order restrictions are placed on the missing values _, and .J through .Z. You can also use the UNTIE= a-option (in the PROC TRANSREG or MODEL statement) to indicate a range of special missing values with estimates that must be weakly ordered within each variable in which they appear but can be untied.

The missing value estimation facilities allow for partitioned or mixed-type variables. For example, a variable can be considered part nominal and part ordinal. Nominal classes of otherwise ordinal variables are coded with special missing values. This feature can be useful with survey research. The class “unfamiliar with the product” in the variable “Rate your preference for ’Brand X’ on a 1 to 9 scale, or if you are unfamiliar with the product, check ’unfamiliar with the product’” is an example. You
can code “unfamiliar with the product” as a special missing value, such as .A. The 1s to 9s can be monotonically transformed, while no monotonic restrictions are placed on the quantification of the “unfamiliar with the product” class.

A variable specified for a LINEAR transformation, with special missing values and ordered categorical missing values, can be part interval, part ordinal, and part nominal. A variable specified for a MONOTONE transformation can have two independent ordinal parts. A variable specified for an UNTIE transformation can have an ordered categorical part and an ordered part without category restrictions. Many other mixes are possible.

**Missing Values, UNTIE, and Hypothesis Tests**

The TRANSREG procedure has the ability to estimate missing data and monotonically transform variables while untying tied values. Estimates of ordinary missing values (.) may all be different. Analyses with UNTIE transformations, the UNTIE=a-option, and ordinary missing data estimation are all prone to degeneracy problems.

Consider the following example. A perfect fit is found by collapsing all observations except the one with two missing values into a single value in Y and X1.

```
data x;
  input y x1 x2 @@;
datalines;
  1 3 7 8 3 9 1 8 6 . . 9 3 9
  8 5 1 6 7 3 2 7 2 1 8 2 . 9 1;
;
proc transreg dummy;
  model linear(y) = linear(x1 x2);
  output;
run;

proc print;
run;
```

**Figure 75.7.** Missing Values Example
Generally, the use of ordinary missing data estimation, the UNTIE transformation, and the UNTIE= a-option should be avoided, particularly with hypothesis tests. With these options, parameters are estimated based on only a single observation, and they can exert tremendous influence over the results. Each of these parameters has one model degree of freedom associated with it, so small or zero error degrees of freedom can also be a problem.

Controlling the Number of Iterations

Several a-options in the PROC TRANSREG or MODEL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the MAXITER= a-option.
- The average absolute change in variable scores from one iteration to the next is less than the value of the CONVERGE= a-option.
- The criterion change is less than the value of the CCONVERGE= a-option.

You can specify negative values for either convergence option if you wish to define convergence only in terms of the other option. The criterion change can become negative when the data have converged so that it is numerically impossible, within machine precision, to increase the criterion. Usually, a negative criterion change is the result of very small amounts of rounding error since the algorithms are (usually) convergent. However, there are other cases where a negative criterion change is a sign of divergence, which is not necessarily an error. When you specify an SSPLINE transformation or the REITERATE or DUMMY a-option, divergence may be perfectly normal.

When there are no monotonicity constraints and there is only one canonical variable in each set, PROC TRANSREG (with the DUMMY a-option) can usually find the optimal solution in only one iteration. (There are no monotonicity constraints when the MONOTONE, MSPLINE, or UNTIE transformations and the UNTIE= and MONOTONE= a-options are not specified. There is only one canonical variable in each set when METHOD=MORALS or METHOD=UNIVARIATE, or when METHOD=REDUNDANCY with only one dependent variable, or when METHOD=CANALS and NCAN=1.)

The initialization iteration is number 0. When there are no monotonicity constraints and there is only one canonical variable in each set, the next iteration shows no change and iteration stops. At least two iterations (0 and 1) are performed with the DUMMY a-option even if nothing changes in iteration 0. The MONOTONE, MSPLINE, and UNTIE variables are not transformed by the dummy variable initialization. Note that divergence with the DUMMY a-option, particularly in the second iteration, is not an error. The initialization iteration is slower and uses more memory than other iterations. However, for many models, specifying the DUMMY a-option can greatly decrease the amount of time required to find the optimal transformations. Furthermore, by solving for the transformations directly instead of iteratively, PROC TRANSREG avoids certain nonoptimal solutions.
You can increase the number of iterations to ensure convergence by increasing the value of the MAXITER= a-option and decreasing the value of the CONVERGE= a-option. Since the average absolute change in standardized variable scores seldom decreases below 1E−11, you should not specify a value for the CONVERGE= a-option less than 1E−8 or 1E−10. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the CONVERGE= and MAXITER= a-options to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, try CONVERGE=1E−8 and MAXITER=50, or CONVERGE=1E−10 and MAXITER=200. Note that you can specify the REITERATE a-option to start iterating where the previous analysis stopped.

**Using the REITERATE Algorithm Option**

You can use the REITERATE a-option to perform additional iterations when PROC TRANSREG stops before the data have adequately converged. For example, suppose that you execute the following code:

```plaintext
proc transreg data=a;
  model mspline(y) = mspline(x1-x5);
  output out=b coefficients;
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations.

```plaintext
proc transreg data=b reiterate;
  model mspline(y) = mspline(x1-x5);
  output out=b coefficients;
run;
```

Note that a WHERE statement is not necessary to exclude the coefficient observations. They are automatically excluded because their _TYPE_ value is not SCORE.

You can also use the REITERATE a-option to specify starting values other than the original values for the transformations. Providing alternate starting points may avoid local optima. Here are two examples.

```plaintext
proc transreg data=a;
  model rank(y) = rank(x1-x5);
  output out=b;
run;

proc transreg data=b reiterate;
  /* Use ranks as the starting point. */
  model mspline(y) = mspline(x1-x5);
  output out=c coefficients;
run;
```
data b;
  set a;
  array tx[6] ty tx1-tx5;
  do j = 1 to 6;
    tx[j] = normal(7);
  end;
run;

proc transreg data=b reiterate;
  /* Use a random starting point. */
  model mspline(y) = mspline(x1-x5);
  output out=c coefficients;
run;

Note that divergence with the REITERATE a-option, particularly in the second it-
eration, is not an error since the initial transformation is not required to be a valid
member of the transformation family. When you specify the REITERATE a-option,
the iteration does not terminate when the criterion change is negative during the first
10 iterations.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable.
This can happen with the MONOTONE, UNTIE, and MSPLINE transformations
when the target is negatively correlated with the original input variable. It can hap-
pen with all transformations when the target is uncorrelated with the original input
variable. When this happens, the procedure modifies the target to avoid a constant
transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the
procedure multiplies the target by $-1$ and tries the optimal scaling again. If the trans-
formation is not monotonic or if the multiplication by $-1$ did not help, the procedure
tries using a random target. If the transformation is still constant, the previous non-
constant transformation is retained. When a constant transformation is avoided by
any strategy, a message is displayed: “A constant transformation was avoided for
name.”

With extreme collinearity, small amounts of rounding error might interact with the
instability of the coefficients to produce target vectors that are not positively corre-
lated with the original scaling. If a regression coefficient for a variable is zero, the
formula for the target for that variable contains a zero divide. In a multiple regression
model, after many iterations, one independent variable can be scaled the same way as
the current scaling of the dependent variable, so the other independent variables have
coefficients of zero. When the constant transformation warning appears, you should
interpret your results with extreme caution, and recheck your model.
Constant Variables

Constant and almost constant variables are zeroed and ignored. As long as the dependent variable is not constant, PROC TRANSREG produces an iteration history table for all models, not just models in which the variables can change. When constant variables are expected and should not be zeroed, specify the NOZEROCONSTANT option.

Character OPSCORE Variables

Character OPSCORE variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered when determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable on the ID statement (ID x;).

Convergence and Degeneracies

When you specify the SSPLINE transformation, divergence is normal. The rest of this section assumes that you did not specify SSPLINE. For all the methods available in PROC TRANSREG, the algorithms are convergent, both in terms of the criterion being optimized and the parameters being estimated. The value of the criterion being maximized (squared multiple correlation, average squared multiple correlation, or average squared canonical correlation) can, theoretically, never decrease from one iteration to the next. The values of the parameters being solved for (the scores and weights of the transformed variables) become stable after sufficient iteration.

In practice, the criterion being maximized can decrease with overiteration. When the statistic has very nearly reached its maximum, further iterations might report a decrease in the criterion in the last few decimal places. This is a normal result of very small amounts of rounding error. By default, iteration terminates when this occurs because, by default, CCONVERGE=0.0. Specifying CCONVERGE=−1, an impossible change, turns off this check for convergence.

Even though the algorithms are convergent, they might not converge to a global optimum. Also, under extreme circumstances, the solution might degenerate. Because two points always form a straight line, the algorithms sometimes try to reach this degenerate optimum. This sometimes occurs when one observation is an ordinal outlier (when one observation has the extreme rank on all variables). The algorithm can reach an optimal solution that ties all other categories producing two points. Similar results can occur when there are many missing values. More generally, whenever there are very few constraints on the scoring of one or more points, degeneracies can be a problem. In a well-behaved analysis, the maximum data change, average data change, and criterion change all decrease at a rapid rate with each iteration. When the rate of change increases for several iterations, the solution might be degenerating.
Implicit and Explicit Intercepts

Depending on several options, the model intercept is nonzero, zero, or implicit, or there is no intercept. Ordinarily, the model contains an explicit nonzero intercept, and the Intercept variable in the OUT= data set contains ones. When TSTANDARD=CENTER or TSTANDARD=Z is specified, the model contains an explicit, zero intercept and the Intercept variable contains zeros. When METHOD=CANALS, the model is fit with centered variables and the Intercept variable is set to missing.

If you specify CLASS with ZERO=NONE or BSPLINE for one or more independent variables, and TSTANDARD=NOMISS or TSTANDARD=ORIGINAL (the default), an implicit intercept model is fit. The intercept is implicit in a set of the independent variables since there exists a set of independent variables the sum of which is a column of ones. All statistics are mean corrected. The implicit intercept is not an option; it is implied by the model.

With METHOD=CANALS, the Intercept variable contains the canonical intercept for canonical coefficients observations: $\hat{\beta}_0 = \hat{y}'\hat{\alpha} - \hat{x}'\hat{\beta}$ where $\hat{Y}\hat{\alpha} \approx X\hat{\beta}$.

Passive Observations

Observations may be excluded from the analysis for several reasons; these include zero weight; zero frequency; missing values in variables designated IDENTITY, CLASS, POINT, EPOINT, QPOINT, SMOOTH, PSPLINE, or BSPLINE; and missing values with the NOMISS $a$-option specified. These observations are passive in that they do not contribute to determining transformations, $R^2$, sums of squares, degrees of freedom, and so on. However, some information can be computed for them. For example, if no independent variable values are missing, predicted values and redundancy variable values can both be computed. Residuals can be computed for observations with a nonmissing dependent and nonmissing predicted value. Canonical variables for dependent variables can be computed when no dependent variables are missing; canonical variables for independent variables can be computed when no independent variables are missing, and so on. Passive observations in the OUT= data set have a blank value for TYPE.

Point Models

The expanded set of independent variables generated from the POINT, EPOINT, and QPOINT expansions can be used to perform ideal point regressions (Carroll 1972) and compute ideal point coordinates for plotting in a biplot (Gabriel 1981). The three types of ideal point coordinates can all be described as transformed coefficients. Assume that $m$ independent variables are specified in one of the three point expansions. Let $b'$ be a $1 \times m$ row vector of coefficients for these variables and one of the dependent variables. Let $R$ be a matrix created from the coefficients of the extra variables. When coordinates are requested with the MPC, MEC, or MQC $o$-options, $b'$ and $R$ are created from multiple regression coefficients. When coordinates are requested with the CPC, CEC, or CQC $o$-options, $b'$ and $R$ are created from canonical coefficients.
If you specify the POINT expansion in the MODEL statement, \( R \) is an \( m \times m \) identity matrix times the coefficient for the sums of squares (_ISSQ_) variable. If you specify the EPOINT expansion, \( R \) is an \( m \times m \) diagonal matrix of coefficients from the squared variables. If you specify the QPOINT expansion, \( R \) is an \( m \times m \) symmetric matrix of coefficients from the squared variables on the diagonal and crossproduct variables off the diagonal. The MPC, MEC, MQC, CPC, CEC, and CQC ideal point coordinates are defined as \(-0.5b^TR^{-1}\). When \( R \) is singular, the ideal point coordinates are infinitely far away and are set to missing, so you should try a simpler version of the model. The version that is simpler than the POINT model is the vector model where no extra variables are created. In the vector model, designate all independent variables as IDENTITY. Then draw vectors from the origin to the COEFFICIENTS points.

Typically, when you request ideal point coordinates, the MODEL statement should consist of a single transformation for the dependent variables (usually IDENTITY, MONOTONE, or MSPLINE) and a single expansion for the independent variables (one of POINT, EPOINT, or QPOINT).

**Redundancy Analysis**

Redundancy analysis (Stewart and Love 1968) is a principal component analysis of multivariate regression predicted values. These first steps show the redundancy analysis results produced by PROC TRANSREG. The specification TSTANDARD=Z standardizes all variables to mean zero and variance one. METHOD=REDUNDANCY specifies redundancy analysis and outputs the redundancy variables to the OUT= data set. The MREDUNDANCY o-option outputs two sets of redundancy analysis coefficients to the OUT= data set.

```plaintext

**Figure 75.8.** Redundancy Analysis Example

The _TYPE_='SCORE' observations of the Red1–Red3 variables contain the redundancy variables. The nonmissing “M REDUND” values are coefficients for predicting the redundancy variables from the independent variables. The nonmissing “R REDUND” values are coefficients for predicting the independent variables from the redundancy variables.

These following steps show how to generate the same results manually. The data set is standardized, predicted values are computed, and principal components of the predicted values are computed. The following statements produce the redundancy variables, shown in **Figure 75.9:**

```plaintext
proc standard data=x out=std m=0 s=1;
title2 'Manually Generate Redundancy Variables';
run;

proc reg noprint data=std;
   model y1-y3 = x1-x4;
   output out=p p=ay1-ay3;
run; quit;

proc princomp data=p cov noprint std out=p;
   var ay1-ay3;
run;

proc print data=p(keep=Prin:);
   format _numeric_ 4.1;
run;
```

Optimal Scaling

An alternating least-squares optimal scaling algorithm can be divided into two major stages. The first stage estimates the parameters of the linear model. These parameters are used to create the predicted values or target for each variable that can be transformed. Each target minimizes squared error (as explained in the discussion of the algorithms in SAS Technical Report R-108. The definition of the target depends on many factors, such as whether a variable is independent or dependent, which algorithm is used (for example, regression, redundancy, CANALS, principal components), and so on. The definition of the target is independent of the transformation family you specify for the variable. However, the target values for a variable typically do not fit the prescribed transformation family for the variable. They might not have the right category structure; they might not have the right order; they might not be a linear combination of the columns of a B-spline basis; and so on.

The second major stage is optimal scaling. Optimal scaling can be defined as a possibly constrained, least-squares regression problem. When you specify an optimal transformation, or when missing data are estimated for any variable, the full representation of the variable is not simply a vector; it is a matrix with more than one column. The optimal scaling phase finds the vector that is a linear combination of the columns of this matrix, that is closest to the target (in terms of minimum squared error), among those that do not violate any of the constraints imposed by the transformation family. Optimal scaling methods are independent of the data analysis method that generated the target. In all cases, optimal scaling can be accomplished by creating a design matrix based on the original scaling of the variable and the transformation family specified for that variable. The optimally scaled variable is a linear combination of the columns of the design matrix. The coefficients of the linear combination are found using (possibly constrained) least squares. Many optimal scaling problems are solved without actually constructing design and projection matrices. The following two sections describe the algorithms used by PROC TRANSREG for optimal scaling. The first section discusses optimal scaling for OPSCORE, MONOTONE, UNTIE, and LINEAR transformations, including how missing values are handled. The second section addresses SPLINE and MSPLINE transformations.
OPSCORE, MONOTONE, UNTIE, and LINEAR Transformations

Two vectors of information are needed to produce the optimally scaled variable: the initial variable scaling vector \( x \) and the target vector \( y \). For convenience, both vectors are first sorted on the values of the initial scaling vector. If you request an UNTIE transformation, the target vector is sorted within ties in the initial scaling vector. The normal SAS System collating sequence for missing and nonmissing values is used. Sorting simply allows constraints to be specified in terms of relations among adjoining coefficients. The sorting process partitions \( x \) and \( y \) into missing and nonmissing parts \( (x'_m, x'_n)' \) and \( (y'_m, y'_n)' \).

Next, PROC TRANSREG determines category membership. Every ordinary missing value (.) forms a separate category. (Three ordinary missing values form three categories.) Every special missing value within the range specified in the UNTIE= \( a \)-option forms a separate category. (If UNTIE= BC and there are three .B and two .C missing values, five categories are formed from them.) For all other special missing values, a separate category is formed for each different value. (If there are four .A missing values, one category is formed from them.)

Each distinct nonmissing value forms a separate category for OPSCORE and MONOTONE transformations (1 1 1 2 2 3 form three categories). Each nonmissing datum forms a separate category for all other transformations (1 1 1 2 2 3 form six categories). Once category membership is determined, category means are computed. Here is an example:

\[
\begin{align*}
  x: & \quad (., ., A, A, B, 1, 1, 1, 2, 2, 3, 3, 3, 4)' \\
  y: & \quad (5, 6, 2, 4, 2, 1, 2, 3, 4, 6, 4, 5, 6, 7)' \\
\end{align*}
\]

OPSCORE and MONOTONE means: 
\[
\begin{align*}
  & (5, 6, 3, 2, 2, 5, 5, 7)' \\
  \text{other means:} & \quad (5, 6, 3, 2, 1, 2, 3, 4, 6, 4, 5, 6, 7)' \\
\end{align*}
\]

The category means are the coefficients of a category indicator design matrix. The category means are the Fisher (1938) optimal scores. For MONOTONE and UNTIE transformations, order constraints are imposed on the category means for the nonmissing partition by merging categories that are out of order. The algorithm checks upward until an order violation is found, then averages downward until the order violation is averaged away. (The average of \( \bar{x}_1 \) computed from \( n_1 \) observations and \( \bar{x}_2 \) computed from \( n_2 \) observations is \( (n_1 \bar{x}_1 + n_2 \bar{x}_2)/(n_1 + n_2) \).) The MONOTONE algorithm (Kruskal 1964, secondary approach to ties) for this example with means for the nonmissing values \( (2, 5, 5, 7)' \) would do the following checks: \( 2 < 5: \text{OK}, 5 = 5: \text{OK}, 5 < 7: \text{OK} \). The means are in the proper order, so no work is needed.

The UNTIE transformation (Kruskal 1964, primary approach to ties) uses the same algorithm on the means of the nonmissing values \( (1, 2, 3, 4, 6, 4, 5, 6, 7)' \) but with different results for this example: \( 1 < 2: \text{OK}, 2 < 3: \text{OK}, 3 < 4: \text{OK}, 4 < 6: \text{OK}, 6 > 4: \text{average} \).
6 and 4 and replace 6 and 4 by the average. The new means of the nonmissing values are \((1 \ 2 \ 3 \ 4 \ 5 \ 5 \ 5 \ 6 \ 7)\). The check resumes: \(4 < 5:\) OK, \(5 = 5:\) OK, \(5 = 5:\) OK, \(5 < 6:\) OK, \(6 < 7:\) OK. If some of the special missing values are ordered, the upward checking, downward averaging method is applied to them also, independently of the other missing and nonmissing partitions. Once the means conform to any required category or order constraints, an optimally scaled vector is produced from the means. The following example results from a MONOTONE transformation.

\[
x: \quad (\ldots.A \ \ldots.A \ .B \ 1 \ 1 \ 1 \ 2 \ 2 \ 3 \ 3 \ 3 \ 4)^
\]

\[
y: \quad (5 \ 6 \ 2 \ 4 \ 2 \ 1 \ 2 \ 3 \ 4 \ 6 \ 4 \ 5 \ 6 \ 7)^
\]

result: \((5 \ 6 \ 3 \ 3 \ 2 \ 2 \ 2 \ 2 \ 5 \ 5 \ 5 \ 5 \ 5 \ 7)\)

The upward checking, downward averaging algorithm is equivalent to creating a category indicator design matrix, solving for least-squares coefficients with order constraints, then computing the linear combination of design matrix columns.

For the optimal transformation LINEAR and for nonoptimal transformations, missing values are handled as just described. The nonmissing target values are regressed onto the matrix defined by the nonmissing initial scaling values and an intercept. In this example, the target vector \(y_n = (1 \ 2 \ 3 \ 4 \ 6 \ 4 \ 5 \ 6 \ 7)\) is regressed onto the design matrix

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 2 & 2 & 3 & 3 & 4
\end{bmatrix}^
\]

Although only a linear transformation is performed, the effect of a linear regression optimal scaling is not eliminated by the later standardization step (unless the variable has no missing values). In the presence of missing values, the linear regression is necessary to minimize squared error.

**SPLINE and MSPLINE Transformations**

The missing portions of variables subjected to SPLINE or MSPLINE transformations are handled the same way as for OPSCORE, MONOTONE, UNTIE, and LINEAR transformations (see the previous section). The nonmissing partition is handled by first creating a B-spline basis of the specified degree with the specified knots for the nonmissing partition of the initial scaling vector and then regressing the target onto the basis. The optimally scaled vector is a linear combination of the B-spline basis vectors using least-squares regression coefficients. An algorithm for generating the B-spline basis is given in de Boor (1978, pp. 134–135). B-splines are both a computationally accurate and efficient way of constructing a basis for piecewise polynomials; however, they are not the most natural method of describing splines.

Consider an initial scaling vector \(x = (1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8 \ 9)\) and a degree three spline with interior knots at 3.5 and 6.5. The B-spline basis for the transformation is the left matrix in Table 75.5, and the natural piecewise polynomial spline basis is the
right matrix. The two matrices span the same column space. The natural basis has an intercept, a linear term, a quadratic term, a cubic term, and two more terms since there are two interior knots. These terms are generated (for knot \(k\) and \(x\) element \(x\)) by the formula \((x - k)^3 \times I(x > k)\). The indicator variable \(I(x > k)\) evaluates to 1.0 if \(x\) is greater than \(k\) and to 0.0 otherwise. If knot \(k\) had been repeated, there would be a \((x - k)^2 \times I(x > k)\) term also. Notice that the fifth column makes no contribution to the curve before 3.5, makes zero contribution at 3.5 (the transformation is continuous), and makes an increasing contribution beyond 3.5. The same pattern of results holds for the last term with knot 6.5. The coefficient of the fifth column represents the change in the cubic portion of the curve after 3.5. The coefficient of the sixth column represents the change in the cubic portion of the curve after 6.5.

</tbody>
</table>

The numbers in the B-spline basis do not have a simple interpretation like the numbers in the natural piecewise polynomial basis. The B-spline basis has a diagonally banded structure. The band shifts one column to the right after every knot. The number of entries in each row that may potentially be nonzero is one greater than the degree. The elements within a row always sum to one. The B-spline basis is accurate because of the smallness of the numbers and the lack of extreme collinearity inherent in the natural polynomials. B-splines are efficient because PROC TRANSREG can take advantage of the sparseness of the B-spline basis when it accumulates crossproducts. The number of required multiplications and additions to accumulate the crossproduct matrix does not increase with the number of knots but does increase with the degree of the spline, so it is much more computationally efficient to increase the number of knots than to increase the degree of the polynomial.

MSPLINE transformations are handled like SPLINE transformations except that constraints are placed on the coefficients to ensure monotonicity. When the coefficients of the B-spline basis are monotonically increasing, the transformation is monotonically increasing. When the polynomial degree is two or less, monotone coefficient splines, integrated splines (Winsberg and Ramsay 1980), and the general class of all monotone splines are equivalent.
Specifying the Number of Knots

Keep the number of knots small (usually less than ten, although you can specify more). A degree three spline with nine knots, one at each decile, can closely follow a large variety of curves. Each spline transformation of degree \( p \) with \( q \) knots fits a model with \( p + q \) parameters. The total number of parameters should be much less than the number of observations. Usually in regression analyses, it is recommended that there be at least five or ten observations for each parameter in order to get stable results. For example, when spline transformations of degree three with nine knots are requested for six variables, the number of observations in the data set should be at least five or ten times 72 (since \( 6 \times (3 + 9) \) is the total number of parameters). The overall model can also have a parameter for the intercept and one or more parameters for each nonspline variable in the model.

Increasing the number of knots gives the spline more freedom to bend and follow the data. Increasing the degree also gives the spline more freedom, but to a lesser extent. Specifying a large number of knots is much better than increasing the degree beyond three.

When you specify NKNOTS=q for a variable with \( n \) observations, then each of the \( q + 1 \) segments of the spline contains \( n/(q + 1) \) observations on the average. When you specify KNOTS=number-list, make sure that there is a reasonable number of observations in each interval.

The following statements find a cubic polynomial transformation of \( X \) and no transformation of \( Y \):

```plaintext
proc transreg;
   model identity(Y)=spline(X);
   output;
run;
```

The following statements find a cubic spline transformation curve for \( X \) that consists of the weighted sum of a single constant, a single straight line, a quadratic curve for the portion of the variable less than 3.0, a different quadratic curve for the portion greater than 3.0 (since the 3.0 knot is repeated), and a different cubic curve for each of the intervals: (minimum to 1.5), (1.5 to 2.4), (2.4 to 3.0), (3.0 to 4.0), and (4.0 to maximum). The transformation is continuous everywhere, its first derivative is continuous everywhere, its second derivative is continuous everywhere except at 3.0, and its third derivative is continuous everywhere except at 1.5, 2.4, 3.0, and 4.0.

```plaintext
proc transreg;
   model identity(Y)=spline(X / knots=1.5 2.4 3.0 3.0 4.0);
   output;
run;
```

The following statements find a quadratic spline transformation that consists of a polynomial \( X \leq t = b_0 + b_1X + b_2X^2 \) for the range \( X < 3.0 \) and a completely different polynomial \( X \geq t = b_3 + b_4X + b_5X^2 \) for the range \( X > 3.0 \). The two curves are not required to be continuous at 3.0.

```plaintext
proc transreg;
   model identity(Y)=spline(X / knots=1.5 2.4 3.0 3.0 4.0);
   output;
run;
```
The following statements categorize $Y$ into 10 intervals and find a step-function transformation. One aspect of this transformation family is unlike all other optimal transformation families. The initial scaling of the data does not fit the restrictions imposed by the transformation family. This is because the initial variable can be continuous, but a discrete step function transformation is sought. Zero degree spline variables are categorized before the first iteration.

```
proc transreg;
  model identity(Y)=spline(X / degree=0 nknots=9);
  output;
run;
```

The following statements find a continuous, piecewise linear transformation of $X$:

```
proc transreg;
  model identity(Y)=spline(X / degree=1 nknots=8);
  output;
run;
```

### SPLINE, BSPLINE, and PSPLINE Comparisons

SPLINE is a transformation. It takes a variable as input and produces a transformed variable as output. Internally, with SPLINE, a B-spline basis is used to find the transformation, which is a linear combination of the columns of the B-spline basis. However, with SPLINE, the basis is not made available in any output.

BSPLINE is an expansion. It takes a variable as input and produces more than one variable as output. The output variables comprise the B-spline basis that is used internally by SPLINE.

PSPLINE is an expansion. It takes a variable as input and produces more than one variable as output. The difference between PSPLINE and BSPLINE is that PSPLINE produces a piecewise polynomial, whereas BSPLINE produces a B-spline. A matrix consisting of a piecewise polynomial basis and an intercept spans the same space as the B-spline matrix, but the basis vectors are quite different. The numbers in the piecewise polynomials can get quite large; the numbers in the B-spline basis range between 0 and 1. There are many more zeros in the B-spline basis.

Interchanging SPLINE, BSPLINE, and PSPLINE should have no effect on the fit of the overall model except for the fact that PSPLINE is much more prone to numerical problems. Similarly, interchanging a CLASS expansion and an OPSCORE transformation should have no effect on the fit of the overall model.
Hypothesis Tests

The TRANSREG procedure has a set of options for testing hypotheses in models with a single dependent variable. The TEST a-option produces an ANOVA table. It tests the null hypothesis that the vector of coefficients for all of the transformations is zero. The SS2 a-option produces a regression table with Type II tests of the contribution of each transformation to the overall model. In some cases, exact tests are provided; in other cases, the tests are approximate, liberal, or conservative.

For two reasons it is typically not appropriate to test hypotheses by using the output from PROC TRANSREG as input to other procedures such as the REG procedure. First, PROC REG has no way of determining how many degrees of freedom were used for each transformation. Second, the Type II sums of squares for the tests of the individual regression coefficients are not correct for the transformation regression model since PROC REG, as it evaluates the effect of each variable, cannot change the transformations of the other variables. PROC TRANSREG uses the correct degrees of freedom and sums of squares.

In an ordinary univariate linear model, there is one parameter for each independent variable, including the intercept. In the transformation regression model, many of the “variables” are used internally in the bases for the transformations. Each basis column has one parameter or scoring coefficient, and each linearly independent column has one model degree of freedom associated with it. Coefficients applied to transformed variables, model coefficients, do not enter into the degrees of freedom calculations. They are by-products of the standardizations and can be absorbed into the transformations by specifying the ADDITIVE a-option. The word parameter is reserved for model and scoring coefficients that have a degree of freedom associated with them.

For expansions, there is one model parameter for each variable created by the expansion (except for all missing CLASS columns and expansions that have an implicit intercept). Each IDENTITY variable has one model parameter. If there are \( m \) POINT variables, they expand to \( m + 1 \) variables and, hence, have \( m + 1 \) model parameters. For \( m \) EPOINT variables, there are \( 2m \) model parameters. For \( m \) QPOINT variables, there are \( m(m + 3)/2 \) model parameters. If a variable with \( m \) categories is designated CLASS, there are \( m - 1 \) parameters. For BSPLINE and PSPLINE variables of DEGREE=\( n \) with NKNOTS=\( k \), there are \( n + k \) parameters. Note that one of the \( n + k + 1 \) BSPLINE columns and one of the \( m \) CLASS(variable / ZERO=NONE) columns are not counted due to the implicit intercept.

There are scoring parameters for missing values in nonexcluded observations. Each ordinary missing value (\( . \)) has one scoring parameter. Each different special missing value (\( . - \) and \( .A \) through \( .Z \)) within each variable has one scoring parameter. Missing values specified in the UNTIE= and MONOTONE= options follow the rules for UNTIE and MONOTONE transformations, which are described later in this chapter.

For all nonoptimal transformations (LOG, LOGIT, ARSIN, POWER, EXP, RANK, BOXCOX), there is one parameter per variable in addition to any missing value scoring parameters.
For SPLINE, OPSCORE, and LINEAR transformations, the number of scoring parameters is the number of basis columns that are used internally to find the transformations minus 1 for the intercept. The number of scoring parameters for SPLINE variables is the same as the number of model parameters for BSPLINE and PSPLINE variables. If DEGREE=\( n \) and NKNOTS=\( k \), there are \( n + k \) scoring parameters. The number of scoring parameters for OPSCORE, SMOOTH, and SSPLINE variables is the same as the number of model parameters for CLASS variables. If there are \( m \) categories, there are \( m - 1 \) scoring parameters. There is one parameter for each LINEAR variable. For SPLINE, OPSCORE, LINEAR, MONOTONE, UNTIE, and MSPLINE transformations, missing value scoring parameters are computed as described previously with the nonoptimal transformations.

The number of scoring parameters for MONOTONE, UNTIE, and MSPLINE transformations is less precise than for SPLINE, OPSCORE, and LINEAR transformations. One way of handling a MONOTONE transformation is to treat it as if it were the same as an OPSCORE transformation. If there are \( m \) categories, there are \( m - 1 \) potential scoring parameters. However, there are typically fewer than \( m - 1 \) unique parameter estimates since some of those \( m - 1 \) scoring parameter estimates may be tied during the optimal scaling to impose the order constraints. Imposing ties on the scoring parameter estimates is equivalent to fitting a model with fewer parameters. So there are two available scoring parameter counts: \( m - 1 \) and a smaller number that is determined during the analysis. Using \( m - 1 \) as the model degrees of freedom for MONOTONE variables (treating OPSCORE and MONOTONE transformations the same way) is conservative, since the MONOTONE scoring parameter estimates are more restricted than the OPSCORE scoring parameter estimates. Using the smaller count (the number of scoring parameter estimates that are different minus 1 for the intercept) in the model degrees of freedom is liberal, since the data and the model together are being used to determine the number of parameters. PROC TRANSREG reports tests using both liberal and conservative degrees of freedom to provide lower and upper bounds on the “true” \( p \)-values.

For the UNTIE transformation, the conservative scoring parameter count is the number of distinct observations, whereas the liberal scoring parameter count is the number of scoring parameter estimates that are different minus 1 for the intercept. Hence, when you specify UNTIE, conservative tests have zero error degrees of freedom unless there are replicated observations.

For MSPLINE variables of DEGREE=\( n \) and NKNOTS=\( k \), the conservative scoring parameter count is \( n + k \), whereas the liberal parameter count is the number of scoring parameter estimates that are different, minus 1 for the intercept. A liberal degrees of freedom of 1 does not necessarily imply a linear transformation. It just implies that \( n + k \) minus the number of ties imposed equals 1. An example of a one degree-of-freedom nonlinear transformation is a two-piece linear transformation in which the slope of one piece is 0.

The number of scoring parameters is determined during each iteration. After the last iteration, enough information is available for the TEST a-option to produce an ANOVA table that reports the overall fit of the model. If you specify the SS2 a-option, further iterations are necessary to test the contribution of each transformation.
to the overall model.

The liberal tests do not compensate for over-parameterization. For example, requesting a spline transformation with \( k \) knots when a linear transformation will suffice results in “liberal” tests that are actually conservative because too many degrees of freedom are being used for the transformations. Use as few knots as possible to avoid this problem.

In ordinary multiple regression, an \( F \) test of the null hypothesis that the coefficient for variable \( x_j \) is zero can be constructed by comparing two linear models. One model is the full model with all parameters, and the other is a reduced model that has all parameters except the parameter for variable \( x_j \). The difference between the model sum of squares for the full model and the model sum of squares for the reduced model is the Type II sum of squares for the test of the null hypothesis that the coefficient for variable \( x_j \) is 0. The numerator of the \( F \) test has one degree of freedom. The mean square error for the full model is the denominator of the \( F \) test of variable \( x_j \). Note that the estimates of the coefficients for the two models are not usually the same. When variable \( x_j \) is removed, the coefficients for the other variables change to compensate for the removal of \( x_j \). In a transformation regression model, the transformations of the other variables must be allowed to change and the numerator degrees of freedom are not always ones. It is not correct to simply let the model coefficients for the transformed variables change and apply the new model coefficients to the old transformations computed with the old scoring parameter estimates. In a transformation regression model, further iteration is needed to test each transformation because all the scoring parameter estimates for other variables must be allowed to change to test the effect of variable \( x_j \). This can be quite time consuming for a large model if the DUMMY a-option cannot be used to solve directly for the transformations.

### Output Data Set

The OUT= output data set can contain a great deal of information; however, in most cases, the output data set contains a small portion of the entire range of available information and is organized for direct input into the %PLOTIT macro or graphical or analysis procedures. For information on the %PLOTIT macro, see Appendix B, “Using the %PLOTIT Macro.”

### Output Data Set Examples

The next section provides a complete list of the contents of the OUT= data set. However, before presenting complete details, this section provides three brief examples, illustrating some typical output data sets.

The first example shows the output data set from a two-way ANOVA model. The following statements produce Figure 75.12:

```plaintext
title 'ANOVA Output Data Set Example';
data ReferenceCell;
   input Y X1 $ X2 $;
datalines;
```
*---Fit Reference Cell Two-Way ANOVA Model---;
proc transreg data=ReferenceCell;
   model identity(Y) = class(X1 | X2);
   output coefficients replace predicted residuals;

Figure 75.12. ANOVA Example Output Data Set Contents

The _TYPE_ variable indicates observation type: score, multiple regression coefficient (parameter estimates), and marginal means. The _NAME_ variable contains the default observation labels, “ROW1”, “ROW2”, and so on, and contains the dependent variable name (Y) for the remaining observations. If you specify an ID statement, _NAME_ contains the values of the first ID variable for score observations. The Y variable is the dependent variable, PY contains the predicted values, RY contains the residuals, and the variables Intercept through X1aX2a contain the design matrix. The X1 and X2 variables are the original CLASS variables.

The next example shows the contents of the output data set from fitting a curve through a scatter plot.

**Figure 75.13.** Predicted Values Example Output Data Set Contents

The OUT= data set contains _TYPE_ and _NAME_ variables. Since no coefficients or coordinates are requested, all observations are _TYPE_='SCORE'. The Y variable is the original dependent variable, TY is the transformed dependent variable, PY contains the predicted values, X is the original independent variable, and TX is the transformed independent variable. The data set also contains an Intercept and transformed intercept TIntercept variable. (In this case, the transformed intercept is the same as the intercept. However, if you specify the TSTANDARD= and ADDITIVE options, these are not always the same.)
The next example shows the results from specifying METHOD=MORALS when there is more than one dependent variable.

**Figure 75.14.** METHOD=MORALS Rolled Output Data Set
If you specify METHOD=MORALS with multiple dependent variables, PROC TRANSREG performs separate univariate analyses and stacks the results in the OUT= data set. For this example, the results of the first analysis are in the partition designated by _DEPVAR_='Spline(Y1)' and the results of the first analysis are in the partition designated by _DEPVAR_='Spline(Y2)', which are the transformation and dependent variable names. Each partition has _TYPE_='SCORE' observations for the variables and a _TYPE_='M COEFFI' observation for the coefficients. In this example, an ID variable is specified, so the _NAME_ variable contains the formatted values of the first ID variable. Since both dependent variables have to go into the same column, the dependent variable is given a new name, _DEPEND_. The dependent variable transformation is named T_DEPEND_, the predicted values variable is named P_DEPEND_, and the residuals variable is named R_DEPEND_.

The independent variables are character OPSCORE variables. By default, PROC TRANSREG replaces character OPSCORE variables with category numbers and discards the original character variables. To avoid this, the input variables are renamed from X1 and X2 to N1 and N2 and the original X1 and X2 are added to the data set as ID variables. The N1 and N2 variables contain the initial values for the OPSCORE transformations, and the TN1 and TN2 variables contain optimal scores. The data set also contains an Intercept and transformed intercept TIntercept variable. The regression coefficients are in the transformation columns, which also contain the variables to which they apply.

Output Data Set Contents

This section presents the various matrices that can result from PROC TRANSREG processing and that appear in the OUT= data set. The exact contents of an OUT= data set depends on many options.

</tbody>
</table>

The independent and dependent variables are created from the original input data. Several potential differences exist between these variables and the actual input data. An intercept variable can be added, new variables can be added for POINT, EPOINT, QPOINT, CLASS, IDENTITY, PSPLINE, and BSPLINE variables, and category numbers are substituted for character OPSCORE variables. These matrices are not always what is input to the first iteration. After the expanded data set is stored for inclusion in the output data set, several things happen to the data before they are input to the first iteration: column means are substituted for missing values; zero degree SPLINE and MSPLINE variables are transformed so that the iterative algorithms get...
step function data as input, which conform to the zero degree transformation family restrictions; and the nonoptimal transformations are performed.

**Details for the UNIVARIATE Method**

When you specify METHOD=UNIVARIATE (in the MODEL or PROC TRANSREG statement), PROC TRANSREG can perform several analyses, one for each dependent variable. While each dependent variable can be transformed, their independent variables are not transformed. The OUT= data set optionally contains all of the _TYPE_=`SCORE` observations, optionally followed by coefficients or coordinates.

**Details for the MORALS Method**

When you specify METHOD=MORALS (in the MODEL or PROC TRANSREG statement), successive analyses are performed, one for each dependent variable. Each analysis transforms one dependent variable and the entire set of the independent variables. All information for the first dependent variable (scores then, optionally, coefficients) appear first. Then all information for the second dependent variable (scores then, optionally, coefficients) appear next. This arrangement is repeated for all dependent variables.

**Details for the CANALS and REDUNDANCY Methods**

For METHOD=CANALS and METHOD=REDUNDANCY (specified in either the MODEL or PROC TRANSREG statement), one analysis is performed that simultaneously transforms all dependent and independent variables. The OUT= data set optionally contains all of the _TYPE_=`SCORE` observations, optionally followed by coefficients or coordinates.

**Variable Names**

As shown in the preceding examples, some variables in the output data set directly correspond to input variables and some are created. All original optimal and nonoptimal transformation variable names are unchanged.

The names of the POINT, QPOINT, and EPOINT expansion variables are also left unchanged, but new variables are created. When independent POINT variables are present, the sum-of-squares variable _ISSQ_ is added to the output data set. For each EPOINT and QPOINT variable, a new squared variable is created by appending `_2`. For example, Dim1 and Dim2 are expanded into Dim1, Dim2, Dim1_2, and Dim2_2. In addition, for each pair of QPOINT variables, a new crossproduct variable is created by combining the two names, for example, Dim1Dim2.

The names of the CLASS variables are constructed from original variable names and levels. Lengths are controlled by the CPREFIX= a-option. For example, when X1 and X2 both have values of ‘a’ and ‘b’, CLASS(X1 | X2 / ZERO=NONE) creates X1 main effect variable names X1a X1b, X2 main effect variable names X2a X2b, and interaction variable names X1aX2a X1aX2b X1bX2a X1bX2b.

PROC TRANSREG then uses these variable names when creating the transformed, predicted, and residual variable names by affixing the relevant prefix and possibly dropping extra characters.
Chapter 75. The TRANSREG Procedure

METHOD=MORALS Variable Names

When you specify METHOD=MORALS and only one dependent variable is present, the output data set is structured exactly as if METHOD=REDUNDANCY (see the section “Details for the CANALS and REDUNDANCY Methods” on page 4625). When more than one dependent variable is present, the dependent variables are output in the variable _DEPEND_, transformed dependent variables are output in the variable T_DEPEND_, predicted values are output in the variable P_DEPEND_, and residuals are output in the variable R_DEPEND_. You can partition the data set into BY groups, one per dependent variable, by referring to the character variable _DEPVAR_, which contains the original dependent variable names and transformations.

Duplicate Variable Names

When the same name is generated from multiple variables in the OUT= data set, new names are created by appending '2', '3', or '4', and so on, until a unique name is created. For 32-character names, the last character is replaced with a numeric suffix until a unique name is created. For example, if there are two output variables that otherwise would be named X, then X and X2 are created instead. If there are two output variables that otherwise would be named ThisIsAThirtyTwoCharacterVarName, then ThisIsAThirtyTwoCharacterVarName and ThisIsAThirtyTwoCharacterVarNam2 are created instead.

OUTTEST= Output Data Set

The OUTTEST= data set contains hypothesis test results. The OUTTEST= data set always contains ANOVA results. When you specify the SS2 a-option, regression tables are also output. When you specify the UTILITIES a-option, conjoint analysis part-worth utilities are also output. The OUTTEST= data set has the following variables:

_DEPVAR_ is a 42-character variable that contains the dependent variable transformation and name.

_TYPE_ is an 8-character variable that contains the table type. The first character is “U” for univariate or “M” for multivariate. The second character is blank. The third character is “A” for ANOVA, “2” for Type II sum of squares, or “U” for UTILITIES. The fourth character is blank. The fifth character is “L” for liberal tests, “C” for conservative tests, or “U” for the usual tests.

Title is an 80-character variable that contains the table title.

Variable is a 42-character variable that contains the independent variable transformations and names for regression tables and blanks for ANOVA tables.

Coefficient contains the multiple regression coefficients for regression tables and underscore special missing values for ANOVA tables.

Statistic is a 24-character variable that contains the names for statistics in other variables, such as Value.
Value contains multivariate test statistics and all other information that does not fit in one of the other columns including R-Square, Dependent Mean, Adj R-Sq, and Coeff Var. Whenever Value is not an underscore special missing value, Statistic describes the contents of Value.

NumDF contains numerator degrees of freedom for $F$ tests.

DenDF contains denominator degrees of freedom for $F$ tests.

SSq contains sums of squares.

MeanSquare contains mean squares.

F contains $F$ statistics.

NumericP contains the $p$-value for the $F$ statistic, stored in a numeric variable.

P is a 9-character variable that contains the formatted $p$-value for the $F$ statistic, including the appropriate $\sim$, $<=$, $>$=, or blank symbols.

LowerLimit contains lower confidence limits on the parameter estimates.

UpperLimit contains upper confidence limits on the parameter estimates.

StdError contains standard errors. For SS2 and UTILITIES tables, standard errors are output for each coefficient with one degree of freedom.

Importance contains the relative importance of each factor for UTILITIES tables.

Label is a 256-character variable that contains variable labels.

There are several possible tables in the OUTTEST= data set corresponding to combinations of univariate and multivariate tests; ANOVA and regression results; and liberal, conservative, and the usual tests. Each table is composed of only a subset of the variables. Numeric variables contain underscore special missing values when they are not a column in a table. Ordinary missing values (.) appear in variables that are part of a table when a nonmissing value cannot be produced. For example, the $F$ is missing for a test with zero degrees of freedom.

---

**Computational Resources**

This section provides information on the computational resources required to use PROC TRANSREG.

Let

\[
\begin{align*}
  n &= \text{number of observations} \\
  q &= \text{number of expanded independent variables} \\
  r &= \text{number of expanded dependent variables} \\
  k &= \text{maximum spline degree} \\
  p &= \text{maximum number of knots}
\end{align*}
\]
• More than 56\((q + r)\) plus the maximum of the data matrix size, the optimal scaling work space, and the covariance matrix size bytes of array space are required. The data matrix size is 8n\((q + r)\) bytes. The optimal scaling work space requires less than 8\((6n + (p + k + 2)(p + k + 11))\) bytes. The covariance matrix size is 4\((q + r)(q + r + 1)\) bytes.

• PROC TRANSREG tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas is an underestimate of the amount of memory needed to handle most problems. These formulas give the absolute minimum amount of memory required. If a utility data set is used, and if memory can be used with perfect efficiency, then roughly the amount of memory stated previously is needed. In reality, most problems require at least two or three times the minimum.

• PROC TRANSREG sorts the data once. The sort time is roughly proportional to \((q + r)n^{3/2}\).

• One regression analysis per iteration is required to compute model parameters (or two canonical correlation analyses per iteration for METHOD=CANALS). The time required for accumulating the crossproducts matrix is roughly proportional to \(n(q + r)^2\). The time required to compute the regression coefficients is roughly proportional to \(q^3\).

• Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special-case algorithms. The number of regressors for the optimal scaling problems depends on the original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each SPLINE and MSPLINE transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to \(nk^2\).

Solving Standard Least-Squares Problems

This section illustrates how to solve some ordinary least-squares problems and generalizations of those problems by formulating them as transformation regression problems. One problem involves finding linear and nonlinear regression functions in a scatter plot. The next problem involves simultaneously fitting two lines or curves through a scatter plot. The last problem involves finding the overall fit of a multi-way main-effects and interactions analysis-of-variance model.

Nonlinear Regression Functions

This example uses PROC TRANSREG in simple regression to find the optimal regression line, a nonlinear but monotone regression function, and a nonlinear non-monotone regression function. A regression line can be found by specifying

```
proc transreg;
  model identity(y) = identity(x);
  output predicted;
run;
```
A monotone regression function (in this case, a monotonically decreasing regression function, since the correlation coefficient is negative) can be found by requesting an MSPLINE transformation of the independent variable, as follows.

```plaintext
proc transreg;
    model identity(y) = mspline(x / nknots=9); 
    output predicted;
run;
```

The monotonicity restriction can be relaxed by requesting a SPLINE transformation of the independent variable, as shown next.

```plaintext
proc transreg;
    model identity(y) = spline(x / nknots=9); 
    output predicted;
run;
```

In this example, it is not useful to plot the transformation $TX$, since $TX$ is just an intermediate result used in finding a regression function through the original $X$ and $Y$ scatter plot.

The following statements provide a specific example of using the TRANSREG procedure for fitting nonlinear regression functions. These statements produce Figure 75.15 through Figure 75.18.

```plaintext

Figure 75.17. A Nonmonotone Regression Function
The squared correlation is only 0.15 for the linear regression, showing that a simple linear regression model is not appropriate for these data. By relaxing the constraints placed on the regression line, the proportion of variance accounted for increases from 0.15 (linear) to 0.61 (monotone) to 0.90 (nonmonotone). Relaxing the linearity constraint allows the regression function to bend and more closely follow the right portion of the scatter plot. Relaxing the monotonicity constraint allows the regression function to bend and more closely follow the right portion of the scatter plot. 

Figure 75.18.  Linear, Monotone, and Nonmonotone Regression Functions
function to follow the periodic portion of the left side of the plot more closely. The nonlinear MSPLINE transformation is a quadratic spline with knots at the deciles. The nonlinear nonmonotonic SPLINE transformation is a cubic spline with knots at the deciles.

Different knots and different degrees would produce slightly different results. The two nonlinear regression functions could be closely approximated by simpler piecewise linear regression functions. The monotone function could be approximated by a two-piece line with a single knot at the elbow. The nonmonotone function could be approximated by a six-piece function with knots at the five elbows.

With this type of problem (one dependent variable with no missing values that is not transformed and one independent variable that is nonlinearly transformed), PROC TRANSREG always iterates exactly twice (although only one iteration is necessary). The first iteration reports the $R^2$ for the linear regression line and finds the optimal transformation of $X$. Since the data change in the first iteration, a second iteration is performed, which reports the $R^2$ for the final nonlinear regression function, and zero data change. The predicted values, which are a linear function of the optimal transformation of $X$, contain the $y$-coordinates for the nonlinear regression function. The variance of the predicted values divided by the variance of $Y$ is the $R^2$ for the fit of the nonlinear regression function. When $X$ is monotonically transformed, the transformation of $X$ is always monotonically increasing, but the predicted values increase if the correlation is positive and decrease for negative correlations.

### Simultaneously Fitting Two Regression Functions

One application of ordinary multiple regression is fitting two or more regression lines through a single scatter plot. With PROC TRANSREG, this application can easily be generalized to fit separate or parallel curves. To illustrate, consider a data set with two groups. The data set has a continuous independent variable $X$, a continuous dependent variable $Y$, and a group membership variable $G$ that has the value 1 for one group and 2 for the other group. The following code shows how PROC TRANSREG can be used to fit two lines, curves, and monotone curves simultaneously through a scatter plot. You can use this code with an appropriate number-list for the KNOTS= t-option.

```plaintext
proc transreg data=A dummy;
   title 'Parallel Lines, Separate Intercepts';
   model identity(Y)=class(G) identity(X);
   output predicted;
run;
proc transreg data=A;
   title 'Parallel Monotone Curves, Separate Intercepts';
   model identity(Y)=class(G) mspline(X / knots=-1.5 to 2.5 by 0.5);
   output predicted;
run;
proc transreg data=A dummy;
   title 'Parallel Curves, Separate Intercepts';
   model identity(Y)=class(G) spline(X / knots=-1.5 to 2.5 by 0.5);
```
output predicted;
run;

proc transreg data=A;
  title 'Separate Slopes, Same Intercept';
  model identity(Y)=class(G / zero=none) * identity(X);
  output predicted;
run;

proc transreg data=A;
  title 'Separate Monotone Curves, Same Intercept';
  model identity(Y) = class(G / zero=none) *
    mspline(X / knots=-1.5 to 2.5 by 0.5);
  output predicted;
run;

proc transreg data=A dummy;
  title 'Separate Curves, Same Intercept';
  model identity(Y) = class(G / zero=none) *
    spline(X / knots=-1.5 to 2.5 by 0.5);
  output predicted;
run;

proc transreg data=A;
  title 'Separate Slopes, Separate Intercepts';
  model identity(Y) = class(G / zero=none) | identity(X);
  output predicted;
run;

proc transreg data=A;
  title 'Separate Monotone Curves, Separate Intercepts';
  model identity(Y) = class(G / zero=none) |
    mspline(X / knots=-1.5 to 2.5 by 0.5);
  output predicted;
run;

proc transreg data=A dummy;
  title 'Separate Curves, Separate Intercepts';
  model identity(Y) = class(G / zero=none) |
    spline(X / knots=-1.5 to 2.5 by 0.5);
  output predicted;
run;

Since the variables X1 and X2 both have a large partition of zeros, the KNOTS= t-option is specified instead of the NKNOTS= t-option. The following example generates an artificial data set with two curves. In the interest of space, only the preceding separate curves, separate intercepts example is run.
title 'Separate Curves, Separate Intercepts';
data A;
do X = -2 to 3 by 0.025;
   G = 1;
   Y = 8*(X*X + 2*cos(X*6)) + 15*normal(7654321);
   output;
   G = 2;
   Y = 4*(-X*X + 4*sin(X*4)) - 40 + 15*normal(7654321);
   output;
end;
run;

proc transreg data=A dummy;
   model identity(Y) = class(G / zero=none) |
                       spline(X / knots=-1.5 to 2.5 by 0.5);
   output predicted;
run;

proc gplot;
   axis1 minor=none;
   axis2 minor=none label=(angle=90 rotate=0);
   symbol1 color=blue v=star i=none;
   symbol2 color=yellow v=dot i=none;
   plot Y*X=1 PY*X=2 /overlay frame cframe=ligr haxis=axis1
      vaxis=axis2 href=0 vref=0;
run; quit;

The previous statements produce Figure 75.19 through Figure 75.20.

Figure 75.19. Fitting Models: Separate Curves, Separate Intercepts
Unbalanced ANOVA without Dummy Variables

This example illustrates that an analysis of variance model can be formulated as a simple regression model with optimal scoring. The purpose of the example is to explain one aspect of how PROC TRANSREG works, not to propose an alternative way of performing an analysis of variance.

Finding the overall fit of a large, unbalanced analysis of variance model can be handled as an optimal scoring problem without creating large, sparse design matrices. For example, consider an unbalanced full main-effects and interactions ANOVA model with six factors. Assume that a SAS data set is created with factor level indicator variables \( C1 \) through \( C6 \) and dependent variable \( Y \). If each factor level consists of nonblank single characters, you can create a cell indicator in a DATA step with the statement

\[
x = \text{compress}(c1 || c2 || c3 || c4 || c5 || c6);
\]

The following statements optimally score \( X \) (using the OPSCORE transformation) and do not transform \( Y \). The final \( R^2 \) reported is the \( R^2 \) for the full analysis of variance model.

```sas
proc transreg;
   model identity(y)=opscore(x);
   output;
run;
```

Figure 75.20. Plot for the Separate Curves, Separate Intercepts Example
The $R^2$ displayed by the preceding statements is the same as the $R^2$ that would be reported by both of the following PROC GLM runs.

```plaintext
proc glm;
  class x;
  model y=x;
run;

proc glm;
  class c1-c6;
  model y=c1|c2|c3|c4|c5|c6;
run;
```

PROC TRANSREG optimally scores the classes of $X$, within the space of a single variable with values linearly related to the cell means, so the full ANOVA problem is reduced to a simple regression problem with an optimal independent variable. PROC TRANSREG requires only one iteration to find the optimal scoring of $X$ but, by default, performs a second iteration, which reports no data changes.

### Hypothesis Tests for Simple Univariate Models

If the dependent variable has one parameter (IDENTITY, LINEAR with no missing values, and so on) and if there are no monotonicity constraints, PROC TRANSREG fits univariate models, which can also be fit with a DATA step and PROC REG. This is illustrated with an artificial data set.

```plaintext
data htex;
  do i = 0.5 to 10 by 0.5;
    x1 = log(i);
    x2 = sqrt(i) + sin(i);
    x3 = 0.05 * i * i + cos(i);
    y = x1 - x2 + x3 + 3 * normal(7);
    x1 = x1 + normal(7);
    x2 = x2 + normal(7);
    x3 = x3 + normal(7);
    output;
  end;
run;
```

Both PROC TRANSREG and PROC REG are run to fit the same polynomial regression model. The ANOVA and regression tables from PROC TRANSREG are displayed in Figure 75.21. The ANOVA and regression tables from PROC REG are displayed in Figure 75.22. The SHORT $a$-option is specified to suppress the iteration history.

Figure 75.22. ANOVA and Regression Output from PROC REG

The PROC TRANSREG regression table differs in several important ways from the parameter estimate table produced by PROC REG. The REG procedure displays standard errors and $t$-tests. PROC TRANSREG displays Type II sums of squares, mean squares, and $F$-tests. The difference is because the numerator degrees of freedom are not always 1, so $t$-tests are not uniformly appropriate. When the degrees of freedom for variable $x_j$ is 1, the following relationships hold between the standard errors ($s_{\beta_j}$) and the Type II sums of squares ($SS_j$):

$$s_{\beta_j} = \left(\hat{\beta_j}^2 / F_j\right)^{1/2}$$

and

$$SS_j = \hat{\beta_j}^2 \times MSE / s_{\beta_j}^2$$

PROC TRANSREG does not provide tests of the individual terms that go into the transformation. (However it could if BSPLINE or PSPLINE had been specified instead of SPLINE.) The test of SPLINE(X1) is the same as the test of the overall
model. The intercepts are different due to the different numbers of variables and their standardizations.

In the next example, both \(X_1\) and \(X_2\) are transformed in the first PROC TRANSREG step, and PROC TRANSREG is used instead of a DATA step to create the polynomials for PROC REG. Both PROC TRANSREG and PROC REG fit the same polynomial regression model. The output from PROC TRANSREG and PROC REG is in Figure 75.23.

```sas
proc transreg data=htex ss2 dummy;
   title 'Two-Variable Polynomial Regression';
   model identity(y) = spline(x1 x2);
run;

proc transreg noprint data=htex maxiter=0;

Figure 75.23. (continued)
There are three iteration histories: one for the overall model and two for the two independent variables. The first PROC TRANSREG iteration history shows the R^2 of 0.17287 for the fit of the overall model. The second is for

\[
\text{model identity}(y) = \text{spline}(x2);
\]

which excludes SPLINE(X1). The third is for

\[
\text{model identity}(y) = \text{spline}(x1);
\]

which excludes SPLINE(X2). The difference between the first and second R^2 times the total sum of squares is the model sum of squares for SPLINE(X1)

\[
(0.17287 - 0.15249) \times 224.143800 = 4.568165
\]

The difference between the first and third R^2 times the total sum of squares is the model sum of squares for SPLINE(X2)

\[
(0.17287 - 0.02604) \times 224.143800 = 32.911247
\]

The TEST statement in PROC REG tests the null hypothesis that the vector of parameters for X1_1 X1_2 X1_3 is zero. This is the same test as the SPLINE(X1)
test used by PROC TRANSREG. Similarly, the PROC REG test that the vector of parameters for $X2_1 \ X2_2 \ X2_3$ is zero is the same as the PROC TRANSREG SPLINE($X2$) test. So for models with no monotonicity constraints and no dependent variable transformations, PROC TRANSREG provides little more than a different packaging of standard least-squares methodology.

**Hypothesis Tests with Monotonicity Constraints**

Now consider a model with monotonicity constraints. This model has no counterpart in PROC REG.

```plaintext
proc transreg data=htex ss2 short;
  title 'Monotone Splines';
  model identity(y) = mspline(x1-x3 / nknots=3);
run;
```

The SHORT `a-option` is specified to suppress the iteration histories. Two ANOVA tables are displayed—one using liberal degrees of freedom and one using conservative degrees of freedom. All sums of squares and the $R^2$s are the same for both tables. What differs are the degrees of freedom and statistics that are computed using degrees of freedom. The liberal test has 8 model degrees of freedom and 11 error degrees of freedom, whereas the conservative test has 15 model degrees of freedom and only 4 error degrees of freedom. The “true” $p$-value is between 0.8462 and 0.9997, so clearly you would fail to reject the null hypothesis. Unfortunately, results are not always this clear. See Figure 75.24.

Figure 75.24. (continued)

Hypothesis Tests with Dependent Variable Transformations

PROC TRANSREG can also provide approximate tests of hypotheses when the dependent variable is transformed, but the output is more complicated. When a dependent variable has more than one degree of freedom, the problem becomes multivariate. Hypothesis tests are performed in the context of a multivariate linear model with the number of dependent variables equal to the number of scoring parameters for the dependent variable transformation. The transformation regression model with a dependent variable transformation differs from the usual multivariate linear model in two important ways. First, the usual assumption of multivariate normality is always violated. This fact is simply ignored. This is one reason that all hypothesis tests in the presence of a dependent variable transformation should be considered approximate at best. Multivariate normality is assumed even though it is known that the assumption is violated.

The second difference concerns the usual multivariate test statistics: Pillai’s Trace, Wilks’ Lambda, Hotelling-Lawley Trace, and Roy’s Greatest Root. The first three statistics are defined in terms of all the squared canonical correlations. Here, there is only one linear combination (the transformation) and, hence, only one squared canonical correlation of interest, which is equal to the $R^2$. It may seem that Roy’s Greatest Root, which uses only the largest squared canonical correlation, is the only statistic of interest. Unfortunately, Roy’s Greatest Root is very liberal and provides only a lower bound on the $p$-value. Approximate upper bounds are provided by adjusting the other three statistics for the one linear combination case. The Wilks’ Lambda,
Pillai’s Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the usual statistics.

These statistics are normally defined in terms of the squared canonical correlations, which are the eigenvalues of the matrix $H(H + E)^{-1}$, where $H$ is the hypothesis sum-of-squares matrix and $E$ is the error sum-of-squares matrix. Here the $R^2$ is used for the first eigenvalue, and all other eigenvalues are set to 0 since only one linear combination is used. Degrees of freedom are computed assuming that all linear combinations contribute to the Lambda and Trace statistics, so the $F$ tests for those statistics provide approximate lower and upper bounds on $p$. In practice, the adjusted Pillai’s Trace is very conservative—perhaps too conservative to be useful. Wilks’ Lambda is less conservative, and the Hotelling-Lawley Trace seems to be the least conservative. The conservative statistics and the liberal Roy’s Greatest Root provide a bound on the true $p$-value. Unfortunately, they sometimes report a bound of 0.0001 and 1.0000.

Here is an example with a dependent variable transformation.

```sas
proc transreg data=htex ss2 dummy short;
   title 'Transform Dependent and Independent Variables';
   model spline(y) = spline(x1-x3);
run;
```

The univariate results match Roy’s Greatest Root results. Clearly, the proper action is to fail to reject the null hypothesis. However, as stated previously, results are not always this clear. See Figure 75.25.

</tbody>
</table>

The Wilks’ Lambda, Pillai’s Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the normal statistics. Roy’s Greatest Root is liberal. These statistics are normally defined in terms of the squared canonical correlations which are the eigenvalues of the matrix H*inv(H+E). Here the R-Square is used for the first eigenvalue and all other eigenvalues are set to zero since only one linear combination is used. Degrees of freedom are computed assuming all linear combinations contribute to the Lambda and Trace statistics, so the F tests for those statistics are conservative. The p values for the liberal and conservative statistics provide approximate lower and upper bounds on p. A liberal test statistic with conservative degrees of freedom and a conservative test statistic with liberal degrees of freedom yield at best an approximate p value, which is indicated by a "~" before the p value.

These statistics are adjusted in the same way as the multivariate statistics above.

Figure 75.25. (continued)

Hypothesis Tests with One-Way ANOVA

One-way ANOVA models are fit with either an explicit or implicit intercept. In implicit intercept models, the ANOVA table of PROC TRANSREG is the correct table for a model with an intercept, and the regression table is the correct table for a model
that does not have a separate explicit intercept. The PROC TRANSREG implicit inter-
cept ANOVA table matches the PROC REG table when the NOINT a-option is
not specified, and the PROC TRANSREG implicit intercept regression table matches
the PROC REG table when the NOINT a-option is specified. The following code
illustrates this relationship. See Figure 75.26 through Figure 75.27 for the results.

```plaintext

Figure 75.27. (continued)

Using the DESIGN Output Option

This example uses PROC TRANSREG and the DESIGN option to prepare an input data set with classification variables for the LOGISTIC procedure. The DESIGN option specifies that the goal is design matrix creation, not analysis. When you specify DESIGN, dependent variables are not required. The DEVIATIONS (or EFFECTS) t-option requests a deviations-from-means (1, 0, −1) coding of the classification variables, which is the same coding the CATMOD procedure uses. See Figure 75.28. PROC TRANSREG automatically creates a macro variable &_trgind that contains the list of independent variables created. This macro is used in the PROC LOGISTIC MODEL statement. See Figure 75.29. For comparison, the same analysis is also performed with PROC CATMOD. See Figure 75.30.

```plaintext
title 'Using PROC TRANSREG to Create a Design Matrix';
data a;
  do y = 1, 2;
    do a = 1 to 4;
```

do b = 1 to 3;
    w = ceil(uniform(1) * 10 + 10);
    output;
    end;
end;
end;
run;

proc transreg data=a design;
    model class(a b / deviations);
    id y w;
    output;
run;

proc print;
    title2 'PROC TRANSREG Output Data Set';
run;

proc logistic;
    title2 'PROC LOGISTIC with Classification Variables';
    freq w;
    model y = &_trgind;
run;

proc catmod data=a;
    title2 'PROC CATMOD Should Produce the Same Results';
    model y = a b;
    weight w;
run;

Discrete Choice Experiments: DESIGN, NORESTORE, NOZERO

A discrete choice experiment is constructed consisting of four product brands, each available at three different prices, $1.49, $1.99, $2.49. In addition, each choice set contains a constant “other” alternative available at $1.49. In the fifth choice set, price is constant. PROC TRANSREG is used to code the design and the PHREG procedure fits the multinomial logit choice model (not shown). See http://www.sas.com/service/techsup/tnote/tnote_stat.html for more information on discrete choice modeling and the multinomial logit model. Look for the latest “Multinomial Logit, Discrete Choice Modeling” report.

**Figure 75.31.** The Fifth Choice Set

For the constant alternative (BRAND = .), the brand coding is a row of zeros due to the NORESTOREMISSING *o-option*, and PRICE is a constant $1.49 (instead of 0) due to the NOZEROCONSTANT *a-option*.

The data set was coded by choice set (BY set). This is a small problem, but with very large problems, it may be necessary to restrict the number of observations that are coded at one time so that the procedure uses less time and memory. Coding by choice set is one option. When coding is performed after the data are merged in, coding by subject and choice set combinations is another option. Alternatively, you can specify DESIGN=n, where n is the number of observations to code at one time. For example, you can specify DESIGN=100 or DESIGN=1000 to process the data set in blocks of 100 or 1000 observations. Specify the NOZEROCONSTANT option to ensure that constant variables within blocks are not zeroed. When you specify DESIGN=n, or perform coding after the data are merged in, specify the dependent variable and any other variables needed for analysis as ID variables.
ANOVA Codings

This set of examples illustrates several different ways to code the same two-way ANOVA model. Figure 75.32 displays the input data set.

```
title 'Two-way ANOVA Models';

data x;
   input a b @@;
   do i = 1 to 2; input y @@; output; end;
   drop i;
   datalines;
1 1 16 14
2 1 1 9
3 1 14 8
1 2 15 13
2 2 12 20
3 2 18 20
;

proc print label;
run;
```

**Figure 75.32.** Input Data Set

The following statements fit a cell-means model. See Figure 75.33 and Figure 75.34.

```
proc transreg data=x ss2 short;
   title2 'Cell-Means Model';
   model identity(y) = class(a * b / zero=none);
   output replace;
run;

proc print label;
run;

**Figure 75.40.** Deviations-From-Means Model, (3, 2) Reference Cell, Design Matrix

The following statements fit a deviations-from-means model, but this time the reference level is the first cell (1,1). This coding is also called effects coding. See Figure 75.41 through Figure 75.42.

```plaintext
proc transreg data=x ss2 short;
   title2 'Deviations From Means, (1,1) Reference Cell';
   model identity(y) = class(a | b / deviations zero=first);
   output replace;
run;

proc print label;
run;

Figure 75.41.  Deviations-From-Means Model, (1, 1) Reference Cell

The parameter estimates are

\[
\hat{\mu} = \bar{y} = 13.33333
\]
\[
\hat{\alpha}_2 = (\bar{y}_{21} + \bar{y}_{22})/2 - \bar{y} = (5 + 16)/2 - 13.33333 = -2.8333
\]
\[
\hat{\alpha}_3 = \frac{y_{31} + y_{32}}{2} - \bar{y} = (11 + 19)/2 - 13.33333 = 1.66667
\]

\[
\hat{\beta}_2 = \frac{(y_{12} + y_{22} + y_{32})}{3} - \bar{y} = (14 + 16 + 19)/3 - 13.33333 = 3
\]

\[
\hat{\gamma}_{22} = \frac{(y_{22} - (\bar{y} + \hat{\alpha}_2 + \hat{\beta}_2))}{16 - (13.33333 + -2.83333 + 3) = 2.5
\]

\[
\hat{\gamma}_{32} = \frac{(y_{32} - (\bar{y} + \hat{\alpha}_3 + \hat{\beta}_2))}{19 - (13.33333 + 1.66667 + 3) = 1
\]

The structural zeros are

\[
\alpha_1 \equiv \beta_1 \equiv \gamma_{11} \equiv \gamma_{12} \equiv \gamma_{21} \equiv \gamma_{31} \equiv 0
\]

Figure 75.44. Less-Than-Full-Rank Model, Design Matrix

Centering

You can use transformation options to center and standardize the variables in several ways. For example, this MODEL statement creates three independent variables, $x$, $x^2$, and $x^3$.

```
model identity(y) = pspline(x);
```

The variables are not centered.

When the CENTER $t$-option is specified, the three independent variables are $x - \bar{x}$, $(x - \bar{x})^2$, and $(x - \bar{x})^3$.

```
model identity(y) = pspline(x / center);
```

Since operations such as squaring occur after the centering, the resulting variables will not always be centered. The CENTER $t$-option is particularly useful with polynomials since centering before squaring and cubing can help reduce collinearity and
numerical problems. For example, if one of your variables is year, with values all
greater than 1900. Squaring and cubing without centering first will create variables
that are all essentially perfectly correlated.

When the TSTANDARD=CENTER t-option is specified, the three independent vari-
ables are \( x - \bar{x}, x^2 - \bar{x}^2, \) and \( x^3 - \bar{x}^3. \)

\[
\text{model identity}(y) = \text{pspline}(x / \text{tstandard=center});
\]

In this case, the variables are squared and cubed and then centered.

### Displayed Output

The display options control the amount of displayed output. The displayed output
can contain

- an iteration history and convergence status table, by default
- an ANOVA table when the TEST, SS2, or UTILITIES a-option is specified
- a regression table when the SS2 a-option is specified
- conjoint analysis part-worth utilities when the UTILITIES a-option is specified
- model details when the DETAIL a-option is specified
- a multivariate ANOVA table when the dependent variable is transformed and
  the TEST or SS2 a-option is specified
- a multivariate regression table when the dependent variable is transformed and
  it is specified
- liberal and conservative ANOVA, multivariate ANOVA, regression, and multi-
  variate regression tables when there are MONOTONE, UNTIE, or MSPLINE
  transformations and the TEST or SS2 a-option is specified

### ODS Table Names

PROC TRANSREG assigns a name to each table it creates. You can use these names
to reference the table when using the Output Delivery System (ODS) to select tables
and create output data sets. These names are listed in the following table.

For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

*1. Liberal and conservative test tables are produced when a MONOTONE, UNTIE, or MSPLINE, transformation is requested.

*2. Multivariate tables are produced when the dependent variable is iteratively transformed.
Example 75.1. Using Splines and Knots

This example illustrates some properties of splines. *Splines* are curves, which are usually required to be continuous and smooth. Splines are usually defined as piecewise polynomials of degree $n$ with function values and first $n - 1$ derivatives that agree at the points where they join. The abscissa values of the join points are called *knots*. The term “*spline*” is also used for polynomials (splines with no knots) and piecewise polynomials with more than one discontinuous derivative. Splines with no knots are generally smoother than splines with knots, which are generally smoother than splines with multiple discontinuous derivatives. Splines with few knots are generally smoother than splines with many knots; however, increasing the number of knots usually increases the fit of the spline function to the data. Knots give the curve freedom to bend to more closely follow the data. Refer to Smith (1979) for an excellent introduction to splines.

In this example, an artificial data set is created with a variable $Y$ that is a discontinuous function of $X$. See the first plot in Output 75.1.7. Notice that the function has four unconnected parts, each of which is a curve. Notice too that there is an overall quadratic trend, that is, ignoring the shapes of the individual curves, at first the $Y$ values tend to decrease as $X$ increases, then $Y$ values tend to increase.

The first PROC TRANSREG analysis fits a linear regression model. The predicted values of $Y$ given $X$ are output and plotted to form the linear regression line. The $R^2$ for the linear regression is 0.10061, and it can be seen from the second plot in Output 75.1.7 that the linear regression model is not appropriate for these data. The following statements create the data set and perform the first PROC TRANSREG analysis. These statements produce Output 75.1.1.

```plaintext
title 'An Illustration of Splines and Knots';

* Create in Y a discontinuous function of X.
*
* Store copies of X in V1-V7 for use in PROC GPLOT.
* These variables are only necessary so that each
* plot can have its own x-axis label while putting
* four plots on a page.;

data A;
array V[7] V1-V7;
X=-0.000001;
do I=0 to 199;
   if mod(I,50)=0 then do;
      C=((X/2)-5)**2;
      if I=150 then C=C+5;
      Y=C;
      end;
   X=X+0.1;
   Y=Y-sin(X-C);
```

```plaintext
```
do J=1 to 7;
    V[J]=X;
end;
output;
end;
run;
* Each of the PROC TRANSREG steps fits a different spline model to the data set created previously. The TRANSREG steps build up a data set with various regression functions. All of the functions are then plotted with the final PROC GPLOT step.
* The OUTPUT statements add new predicted values variables to the data set, while the ID statements save all of the previously created variables that are needed for the plots.

proc transreg data=A;
    model identity(Y) = identity(X);
    title2 'A Linear Regression Function';
    output out=A pprefix=Linear;
    id V1-V7;
run;

</tr>
</tbody>
</table>

The second PROC TRANSREG analysis finds a degree two spline transformation with no knots, which is a quadratic polynomial. The spline is a weighted sum of a single constant, a single straight line, and a single quadratic curve. The $R^2$ increases from 0.10061, which is the linear fit value from before, to 0.40720. It can be seen from the third plot in Output 75.1.7 that the quadratic regression function does not fit any of the individual curves well, but it does follow the overall trend in the data. Since the overall trend is quadratic, a degree three spline with no knots (not shown) increases $R^2$ by only a small amount. The following statements perform the quadratic analysis and produce Output 75.1.2.

    proc transreg data=A;
The next step uses the default degree of three, for a piecewise cubic polynomial, and requests knots at the known break points, $X=5$, 10, and 15. This requests a spline that is continuous, has continuous first and second derivatives, and has a third derivative that is discontinuous at 5, 10, and 15. The spline is a weighted sum of a single constant, a single straight line, a single quadratic curve, a cubic curve for the portion of $X$ less than 5, a different cubic curve for the portion of $X$ between 5 and 10, a different cubic curve for the portion of $X$ between 10 and 15, and another cubic curve for the portion of $X$ greater than 15. The new $R^2$ is 0.61730, and it can be seen from the fourth plot (in Output 75.1.7) that the spline is less smooth than the quadratic polynomial and it follows the data more closely than the quadratic polynomial. The following statements perform this analysis and produce Output 75.1.3:

```
proc transreg data=A;
    model identity(Y) = spline(X / knots=5 10 15);
    title2 'A Cubic Spline Regression Function';
    title3 'The Third Derivative is Discontinuous at X=5, 10, 15';
    output out=A pprefix=Cub1;
    id V1-V7 LinearY QuadY;
run;
```
**Output 75.1.3.** Fitting a Piecewise Cubic Polynomial

<table>
<thead>

<td>0.51670</td>
<td>Converged</td>
</tr>
</tbody>
</table>

Algorithm converged.

The same model could be fit with a DATA step and PROC REG, as follows. (The output from the following code is not displayed.)

```plaintext
data B; /* A is the data set used for transreg */
set a(keep=X Y);
  X1=X;        /* X */
  X2=X**2;     /* X squared */
  X3=X**3;     /* X cubed */
  X4=(X>5)*(X-5)**3;     /* change in X**3 after 5 */
  X5=(X>10)*(X-10)**3;    /* change in X**3 after 10 */
  X6=(X>15)*(X-15)**3;    /* change in X**3 after 15 */
run;

proc reg;
  model Y=X1-X6;
run;
```

In the next step each knot is repeated three times, so the first, second, and third derivatives are discontinuous at X=5, 10, and 15, but the spline is required to be continuous at the knots. The spline is a weighted sum of the following:

- a single constant
- a line for the portion of X less than 5
- a quadratic curve for the portion of X less than 5
- a cubic curve for the portion of X less than 5
- a different line for the portion of X between 5 and 10
- a different quadratic curve for the portion of X between 5 and 10
- a different cubic curve for the portion of X between 5 and 10
- a different line for the portion of X between 10 and 15
- a different quadratic curve for the portion of X between 10 and 15
- a different cubic curve for the portion of X between 10 and 15
• another line for the portion of \( X \) greater than 15
• another quadratic curve for the portion of \( X \) greater than 15
• and another cubic curve for the portion of \( X \) greater than 15

The spline is continuous since there is not a separate constant in the formula for the spline for each knot. Now the \( R^2 \) is 0.95542, and the spline closely follows the data, except at the knots. The following statements perform this analysis and produce Output 75.1.4:

```
proc transreg data=A;
   model identity(y) = spline(x / knots=5 5 10 10 15 15 15);
   title3 'First - Third Derivatives Discontinuous at X=5, 10, 15';
   output out=A pprefix=Cub3;
   id V1-V7 LinearY QuadY Cub1Y;
run;
```

Output 75.1.4. Piecewise Polynomial with Discontinuous Derivatives

The same model could be fit with a DATA step and PROC REG, as follows. (The output from the following code is not displayed.)

```
data B;
   set a(keep=X Y);
   X1=X; /* X */
   X2=X**2; /* X squared */
   X3=X**3; /* X cubed */
   X4=(X>5) * (X- 5); /* change in X after 5 */
   X5=(X>10) * (X-10); /* change in X after 10 */
   X6=(X>15) * (X-15); /* change in X after 15 */
   X7=(X>5) * ((X-5)**2); /* change in X**2 after 5 */
   X8=(X>10) * ((X-10)**2); /* change in X**2 after 10 */
   X9=(X>15) * ((X-15)**2); /* change in X**2 after 15 */
   X10=(X>5) * ((X-5)**3); /* change in X**3 after 5 */
   X11=(X>10) * ((X-10)**3); /* change in X**3 after 10 */
```
X12=(X>15) * ((X-15)**3); /* change in X**3 after 15 */
run;

proc reg;
  model Y=X1-X12;
run;

When the knots are repeated four times in the next step, the spline function is discontinuous at the knots and follows the data even more closely, with an $R^2$ of 0.99254. In this step, each separate curve is approximated by a cubic polynomial (with no knots within the separate polynomials). The following statements perform this analysis and produce Output 75.1.5:

proc transreg data=A;
  model identity(Y) = spline(X / knots=5 5 5 5 10 10 10 10 15 15 15 15);
  title3 'Discontinuous Function and Derivatives';
  output out=A pprefix=Cub4;
  id V1-V7 LinearY QuadY Cub1Y Cub3Y;
run;

Algorithm converged.

To solve this problem with a DATA step and PROC REG, you would need to create all of the variables in the preceding DATA step (the B data set for the piecewise polynomial with discontinuous third derivatives), plus the following three variables.

X13=(X > 5); /* intercept change after 5 */
X14=(X > 10); /* intercept change after 10 */
X15=(X > 15); /* intercept change after 15 */

The last two steps use the NKNOTS= t-option to specify the number of knots but not their location. NKNOTS=4 places knots at the quintiles while NKNOTS=9 places knots at the deciles. The spline and its first two derivatives are continuous. The $R^2$ values are 0.74450 and 0.95256. Even though the knots are placed in the wrong
places, the spline can closely follow the data with NKNOTS=9. The following state-
ments produce Output 75.1.6.

```plaintext
proc transreg data=A;
  model identity(Y) = spline(X / nknots=4);
  title3 'Four Knots';
  output out=A pprefix=Cub4k;
  id V1-V7 LinearY QuadY Cub1Y Cub3Y Cub4Y;
run;

proc transreg data=A;
  model identity(Y) = spline(X / nknots=9);
  title3 'Nine Knots';
  output out=A pprefix=Cub9k;
  id V1-V7 LinearY QuadY Cub1Y Cub3Y Cub4Y Cub4kY;
run;
```

```

Example 75.1. Using Splines and Knots ♦ 4685
Output 75.1.7. Plots Summarizing Analysis for Spline Example
Output 75.1.7. (continued)
These next steps show how to find optimal spline transformations of variables in one data set and apply the same transformations to variables in another data set. These steps produce two artificial data sets, in which the variable \( Y \) is a linear function of nonlinear transformations of the variables \( X, W, \) and \( Z \).

```
title2 'Scoring Spline Variables';

data x;
  do i = 1 to 5000;
    w = normal(7);
    x = normal(7);
    z = normal(7);
    y = w * w + log(5 + x) + sin(z) + normal(7);
    output;
  end;
run;

data z;
  do i = 1 to 5000;
    w = normal(1);
    x = normal(1);
    z = normal(1);
    y = w * w + log(5 + x) + sin(z) + normal(1);
    output;
  end;
run;
```

First, you run PROC TRANSREG asking for spline transformations of the three independent variables. You must use the EXKNOTS= t-option, because you need to use the same knots, both interior and exterior, with both data sets. By default the exterior knots will be different if the minima and maxima are different in the two data sets, so you will get the wrong results if you do not specify the EXKNOTS= t-option with values less than the minima and greater than the maxima of the two \( Y \) variables.

```
ods output splinecoef=c;
proc transreg data=x dum det ss2;
  model ide(y) = spl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
  output out=d;
run;
```

The nonprinting “SplineCoef” table is output to a SAS data set. This data set contains the coefficients used to get the spline transformations and can be used to transform variables in other data sets. These coefficients are also in the details table. However, in the “SplineCoef” table they are in a form directly suitable for use with PROC SCORE.

This next step reads a different input data set and generates an output data set with the B-spline basis for each of the variables. Note that the same interior and exterior knots are used in both the previous and the next steps.
Example 75.2. Using Splines and Knots

```
proc transreg data=z design;
  model bspl(w x z / knots=-1.5 to 1.5 by 0.5 exknots=-5 5);
  output out=b;
run;
```

These next three steps score the B-spline bases created in the previous step using the coefficients generated in the first PROC TRANSREG step. PROC SCORE is run once for each SPLINE variable.

```
proc score data=b score=c out=o1(rename=(spline=bw w=nw));
  var w:;
run;
```

```
proc score data=b score=c out=o2(rename=(spline=bx x=nx));
  var x:;
run;
```

```
proc score data=b score=c out=o3(rename=(spline=bz z=nz));
  var z:;
run;
```

The next steps merge the three transformations with the original data and plot the results. The plots in Output 75.1.8 show that in fact the two transformations for each variable, original and scored, are the same function. Furthermore, PROC TRANSREG found the functional forms that were used to generate the data: quadratic for \(W\), log for \(X\), and sine for \(Z\).

```
goptions goutmode=replace nodisplay;
data all;
  merge d(keep=w x z tw tx tz) o1(keep=nw bw)
    o2(keep=nx bx) o3(keep=nz bz);
run;
```

```
proc gplot data=all;
  title3 'Exterior Knots Specified - Curves are the Same';
  symbol1 color=blue v=none i=smooths;
  symbol2 color=red v=none i=smooths;
  plot tw * w = 1 bw * nw = 2 / overlay name='tregspl1';
  plot tx * x = 1 bx * nx = 2 / overlay name='tregspl2';
  plot tz * z = 1 bz * nz = 2 / overlay name='tregspl3';
run; quit;
```

```
goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:tregspl1 2:tregspl3 3:tregspl2;
run; quit;
```
**Example 75.2. Nonmetric Conjoint Analysis of Tire Data**

This example uses PROC TRANSREG to perform a nonmetric conjoint analysis of tire preference data. Conjoint analysis decomposes rank ordered evaluation judgments of products or services into components based on qualitative product attributes.
For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original rank ordering. (This example is a greatly simplified introductory example.)

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo)," prices ($69.99, $74.99, $79.99), expected tread life (50,000, 60,000, 70,000), and road hazard insurance plans (Yes, No). There are $3 \times 3 \times 3 \times 2 = 54$ possible combinations. From these, 18 combinations are selected that form an efficient experimental design for a main effects model. The combinations are then ranked from 1 (most preferred) to 18 (least preferred). In this simple example, there is one set of rankings. A real conjoint study would have many more.

First, the FORMAT procedure is used to specify the meanings of the factor levels, which are entered as numbers in the DATA step along with the ranks. PROC TRANSREG is used to perform the conjoint analysis. A maximum of 50 iterations is requested. The specification Monotone(Rank / Reflect) in the MODEL statement requests that the dependent variable Rank should be monotonically transformed and reflected so that positive utilities mean high preference. The variables Brand, Price, Life, and Hazard are designated as CLASS variables, and the part-worth utilities are constrained by ZERO=SUM to sum to zero within each factor. The UTILITIES a-option displays the conjoint analysis results.

The Importance column of the Utilities Table shows that price is the most important attribute in determining preference (57%), followed by expected tread life (18%), brand (15%), and road hazard insurance (10%). Looking at the Utilities Table for the maximum part-worth utility within each attribute, you see from the results that the most preferred combination is Pirogi brand tires, at $69.99, with a 70,000 mile expected tread life, and road hazard insurance. This product is not actually in the data set. The sum of the part-worth utilities for this combination is

$$20.64 = 9.50 + 1.90 + 5.87 + 2.41 + 0.96$$

The following statements produce Output 75.2.1:

```plaintext

Example 75.3. Metric Conjoint Analysis of Tire Data

This example, which is more detailed than the previous one, uses PROC TRANSREG to perform a metric conjoint analysis of tire preference data. Conjoint analysis can be used to decompose preference ratings of products or services into components based on qualitative product attributes. For each level of each attribute of interest, a numerical “part-worth utility” value is computed. The sum of the part-worth utilities for each product is an estimate of the utility for that product. The goal is to compute part-worth utilities such that the product utilities are as similar as possible to the original ratings. Metric conjoint analysis, as shown in this example, fits an ordinary linear model directly to data assumed to be measured on an interval scale. Nonmetric conjoint analysis, as shown in Example 75.2, finds an optimal monotonic transformation of original data before fitting an ordinary linear model to the transformed data.

This example has three parts. In the first part, an experimental design is created. In the second part, a DATA step creates descriptions of the stimuli for the experiment. The third part of the example performs the conjoint analyses.

The stimuli for the experiment are 18 hypothetical tires. The stimuli represent different brands (Goodstone, Pirogi, Machismo),* prices ($69.99, $74.99, $79.99), expected tread life (50,000, 60,000, 70,000), and road hazard insurance plans (Yes, No).

For a conjoint study such as this, you need to create an experimental design with 3 three-level factors, 1 two-level factor, and 18 combinations or runs. The easiest way to get this design is with the %MktEx autocall macro. The %MktEx macro requires

*In real conjoint experiments, real brand names would be used
you to specify the number of levels of each of the four factors, followed by N=18, the number of runs. Specifying a random number seed, while not strictly necessary, helps ensure that the design is reproducible. The %MktLab macro assigns the actual factor names instead of the default names X1, X2, and so on, and it assigns formats to the factor levels. The %MktEval macro helps you evaluate the design. It shows how correlated or independent the factors are, how often each factor level appears in the design, how often each pair occurs for every factor pair, and how often each product profile or run occurs in the design. See Kuhfeld (2003) for more information on these tools and their use in conjoint and choice modeling.

```sas
title 'Tire Study, Experimental Design';

proc format;
  value BrandF
    1 = 'Goodstone'
    2 = 'Pirogi'
    3 = 'Machismo';
  value PriceF
    1 = '$69.99'
    2 = '$74.99'
    3 = '$79.99';
  value LifeF
    1 = '50,000'
    2 = '60,000'
    3 = '70,000';
  value HazardF
    1 = 'Yes'
    2 = 'No';
run;

%mktex(3 3 3 2, n=18, seed=448)
%mktlab(vars=Brand Price Life Hazard, out=sasuser.TireDesign,
    Life LifeF6. Hazard HazardF3.)
%mkteval;

proc print data=sasuser.TireDesign;
run;
```

The %MktEx macro output displayed in Output 75.3.1 shows you that the design is 100% efficient, which means it is orthogonal and balanced. The %MktEval macro output displayed in Output 75.3.2 shows you that all of the factors are uncorrelated or orthogonal, the design is balanced (each level occurs once), and every pair of factor levels occurs equally often (again showing that the design is orthogonal). The n-way frequencies show that each product profile occurs once (there are no duplicates). The design is shown in Output 75.3.3. The design is automatically randomized (the profiles were sorted into a random order and the original levels are randomly reassigned). Orthogonality, balance, randomization, and other design concepts are discussed in detail in Kuhfeld (2003).

</tbody>
</table>

The third part of the example performs the conjoint analyses. The DATA step reads the data. Only the ratings are entered, one row per subject. Real conjoint studies have many more subjects than five. The TRANSPose procedure transposes this \(5 \times 18\) data set into an \(18 \times 5\) data set that can be merged with the factor level data set `sasuser.TireDesign`. The next DATA step does the merge. The PRINT procedure displays the input data set.

PROC TRANSREG fits the five individual conjoint models, one for each subject. The UTILITIES a-option displays the conjoint analysis results. The SHORT a-option
suppresses the iteration histories, OUTTEST=Utils creates an output data set with all of the conjoint results, and the SEPARATORS= option requests that the labels constructed for each category contain two blanks between the variable name and the level value. The ODS select statement is used to limit the displayed output. The MODEL statement specifies IDENTITY for the ratings, which specifies a metric conjoint analysis—the ratings are not transformed. The variables Brand, Price, Life, and Hazard are designated as CLASS variables, and the part-worth utilities are constrained to sum to zero within each factor.

The following statements produce Output 75.3.5:

```plaintext
title 'Tire Study, Data Entry, Preprocessing';

These following statements summarize the results. Three tables are displayed: all of the importance values, the average importance, and the part-worth utilities. The first DATA step selects the importance information from the \texttt{Utils} data set. The final assignment statement stores just the variable name from the label relying on the fact that the separator is two blanks. PROC TRANSPOSE creates the data set of importances, one row per subject, and PROC PRINT displays the results. The MEANS procedure displays the average importance of each attribute across the subjects. The next DATA step selects the part-worth utilities information from the \texttt{Utils} data set. PROC TRANSPOSE creates the data set of utilities, one row per subject, and PROC PRINT displays the results.

Based on the importance values, price is the most important attribute for some of the respondents, but expected tread life is most important for others. On the average, price is most important followed closely by expected tread life. Brand and road hazard insurance are less important. Both Goodstone and Pirogi are the most preferred brands by some of the respondents. All respondents preferred a lower price over a higher price, a longer tread life, and road hazard insurance.

Example 75.4. Transformation Regression of Exhaust Emissions Data

In this example, the MORALS algorithm is applied to data from an experiment in which nitrogen oxide emissions from a single cylinder engine are measured for various combinations of fuel, compression ratio, and equivalence ratio. The data are provided by Brinkman (1981).
The equivalence ratio and nitrogen oxide variables are continuous and numeric, so spline transformations of these variables are requested. Each spline is degree three with nine knots (one at each decile) in order to allow PROC TRANSREG a great deal of freedom in finding transformations. The compression ratio variable has only five discrete values, so an optimal scoring is requested. The character variable Fuel is nominal, so it is designated as a classification variable. No monotonicity constraints are placed on any of the transformations. Observations with missing values are excluded with the NOMISS _a-option_.

The squared multiple correlation for the initial model is less than 0.25. PROC TRANSREG increases the \( R^2 \) to over 0.95 by transforming the variables. The transformation plots show how each variable is transformed. The transformation of compression ratio (TCpRatio) is nearly linear. The transformation of equivalence ratio (TEqRatio) is nearly parabolic. It can be seen from this plot that the optimal transformation of equivalence ratio is nearly uncorrelated with the original scoring. This suggests that the large increase in \( R^2 \) is due to this transformation. The transformation of nitrogen oxide (TNOx) is something like a log transformation.

These results suggest the parametric model

\[
\log(\text{NOX}) = b_0 + b_1 \times \text{EqRatio} + b_2 \times \text{EqRatio}^2 + b_3 \times \text{CpRatio} + \sum_j b_j \text{class}_j(\text{Fuel}) + \text{error}.
\]

You can perform this analysis with PROC TRANSREG using the following MODEL statement:

```
model log(\text{NOx}) = psp(\text{EqRatio} / \text{deg}=2) identity(\text{CpRatio})
   class(\text{Fuel} / \text{zero}=\text{first});
```

The LOG transformation computes the natural log. The PSPLINE expansion expands EqRatio into a linear term, EqRatio, and a squared term, EqRatio\(^2\). A linear transformation of CpRatio and a dummy variable expansion of Fuel is requested with the first level as the reference level. These should provide a good parametric operationalization of the optimal transformations. The final model has an \( R^2 \) of 0.91 (smaller than before since the model uses fewer degrees of freedom, but still quite good).

The following statements produce Output 75.4.1 through Output 75.4.2:

```
title 'Gasoline Example';
data Gas;
   input Fuel :$8. CpRatio EqRatio NOx @@;
   label Fuel = 'Fuel'
      CpRatio = 'Compression Ratio (CR)';
```
EqRatio = 'Equivalence Ratio (PHI)'
NOx = 'Nitrogen Oxide (NOx)';

</tr>
</tbody>
</table>

The Wilks’ Lambda, Pillai’s Trace, and Hotelling-Lawley Trace statistics are a conservative adjustment of the normal statistics. Roy’s Greatest Root is liberal. These statistics are normally defined in terms of the squared canonical correlations which are the eigenvalues of the matrix H*inv(H+E). Here the R-Square is used for the first eigenvalue and all other eigenvalues are set to zero since only one linear combination is used. Degrees of freedom are computed assuming all linear combinations contribute to the Lambda and Trace statistics, so the F tests for those statistics are conservative. The p values for the liberal and conservative statistics provide approximate lower and upper bounds on p. A liberal test statistic with conservative degrees of freedom and a conservative test statistic with liberal degrees of freedom yield at best an approximate p value, which is indicated by a “~” before the p value.

Example 75.5. Preference Mapping of Cars Data

This example uses PROC TRANSREG to perform a preference mapping (PREFMAP) analysis (Carroll 1972) of car preference data after a PROC PRINQUAL principal component analysis. The PREFMAP analysis is a response surface regression that locates ideal points for each dependent variable in a space defined by the independent variables.

The data are ratings obtained from 25 judges of their preference for each of 17 automobiles. The ratings were made on a zero (very weak preference) to nine (very strong preference) scale. These judgments were made in 1980 about that year’s products. There are two character variables that indicate the manufacturer and model of the automobile. The data set also contains three ratings: miles per gallon (MPG), projected reliability (Reliability), and quality of the ride (Ride). These ratings are on a one (bad) to five (good) scale. PROC PRINQUAL creates an OUT= data set containing standardized principal component scores (Prin1 and Prin2), along with the ID variables MODEL, MPG, Reliability, and Ride.

The first PROC TRANSREG step fits univariate regression models for MPG and Reliability. All variables are designated IDENTITY. A vector drawn in the plot of Prin1 and Prin2 from the origin to the point defined by an attribute’s regression coefficients approximately shows how the cars differ on that attribute. Refer to Carroll (1972) for more information. The Prin1 and Prin2 columns of the TRESULT1 OUT= data set contain the car coordinates (TYPE='SCORE' observations) and endpoints of the MPG and Reliability vectors (TYPE='M COEFFI' observations).

The second PROC TRANSREG step fits a univariate regression model with Ride designated IDENTITY, and Prin1 and Prin2 designated POINT. The POINT expansion creates an additional independent variable _ISSQ_, which contains the sum of Prin1 squared and Prin2 squared. The OUT= data set TRESULT2 contains no _TYPE_='SCORE' observations, only ideal point (_TYPE_='M POINT') coordinates for Ride. The coordinates of both the vectors and the ideal points are output by specifying COORDINATES in the OUTPUT statement in PROC TRANSREG.

A vector model is used for MPG and Reliability because perfectly efficient and reliable cars do not exist in the data set. The ideal points for MPG and Reliability are far removed from the plot of the cars. It is more likely that an ideal point for quality of the ride is in the plot, so an ideal point model is used for the ride variable. Refer to Carroll (1972) and Schiffman, Reynolds, and Young (1981) for discussions of the vector model and point models (including the EPOINT and QPOINT versions of the point model that are not used in this example).

The final DATA step combines the two output data sets and creates a data set suitable for the %PLOTIT macro. (For information on the %PLOTIT macro, see Appendix B, “Using the %PLOTIT Macro.”) The plot contains one point per car and one point for each of the three ratings. The %PLOTIT macro options specify the input data set, how to handle anti-ideal points (described later), and where to draw horizontal and vertical reference lines. The DATATYPE= option specifies that the input data set contains results of a PREFMAP vector model and a PREFMAP ideal point model.
This instructs the macro to draw vectors to _Type_ = ‘M COEFFI’ observations and circles around _Type_ = ‘M POINT’ observations.

An unreliable to reliable direction extends from the left and slightly below the origin to the right and slightly above the origin. The Japanese and European Cars are rated, on the average, as more reliable. A low MPG to good MPG direction extends from the top left of the plot to the bottom right. The smaller cars, on the average, get better gas mileage. The ideal point for Ride is in the top, just right of the center of the plot. Cars near the Ride ideal point tend to have a better ride than cars far away. It can be seen from the iteration history tables that none of these ratings perfectly fits the model, so all of the interpretations are approximate.

The Ride point is a “negative-negative” ideal point. The point models assume that small ratings mean the object (car) is similar to the rating name and large ratings imply dissimilarity to the rating name. Because the opposite scoring is used, the interpretation of the Ride point must be reversed to a negative ideal point (bad ride). However, the coefficient for the _ISSQ_ variable is negative, so the interpretation is reversed again, back to the original interpretation. Anti-ideal points are taken care of in the %PLOTIT macro. Specify ANTIIDEA=1 when large values are positive or ideal and ANTIIDEA=-1 when small values are positive or ideal.

The following statements produce Output 75.5.1 through Output 75.5.2:

Example 75.6. Box Cox

This example illustrates finding a Box-Cox transformation (see the “Box-Cox Transformations” section on page 4595) of some artificial data. Data were generated from the model

\[ y = e^{x+\epsilon} \]

where \( \epsilon \sim N(0, 1) \). The transformed data can be fit with a linear model

\[ \log(y) = x + \epsilon \]
These statements produce Output 75.6.1.

```
output 75.6.1.
title 'Basic Box-Cox Example';
data x;
  do x = 1 to 8 by 0.025;
    y = exp(x + normal(7));
    output;
  end;
run;
proc transreg data=x ss2 details;
  title2 'Defaults';
  model boxcox(y) = identity(x);
run;
```

< - Best Lambda
* - Confidence Interval
+ - Convenient Lambda
PROC TRANSREG correctly selects the log transformation $\lambda = 0$, with a narrow confidence interval. The maximum of the log likelihood function is flagged with the less-than sign ($<$), and the convenient power parameter of $\lambda = 0$ in the confidence interval is flagged by the plus sign ($+$). The rest of the output is shown next in Output 75.6.2.

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.
This next example uses several options. The LAMBDA= option specifies power parameters sparsely from -2 to -0.5 and 0.5 to 2 just to get the general shape of the log likelihood function in that region. Between -0.5 and 0.5, more power parameters are tried. The CONVENIENT option is specified so that if a power parameter like $\lambda = 1$ or $\lambda = 0$ is found in the confidence interval, it will be used instead of the optimal power parameter. PARAMETER=2 is specified to add 2 to each $y$ before performing the transformations. ALPHA=0.00001 specifies a wide confidence interval.

These statements produce Output 75.6.3.

```
proc transreg data=x ss2 details;
  title2 'Several Options Demonstrated';
  model boxcox(y / lambda=-2 -1 -0.5 to 0.5 by 0.05 1 2
                  convenient
                  parameter=2
                  alpha=0.00001)
    = identity(x);
run;
```
The results show that the optimal power parameter is -0.1 but 0 is in the confidence interval, hence a log transformation is chosen. The rest of the output is shown next in Output 75.6.4.

</table>

The above statistics are not adjusted for the fact that the dependent variable was transformed and so are generally liberal.

The next part of this example shows how to make graphical displays of the Box-Cox transformation results. Plots include the log likelihood function with the confidence interval, root mean squared error as a function of the power parameter, R^2 as a function of the power parameter, the Box-Cox transformation of the variable y, the original scatter plot based on the untransformed data, and the new scatter plot based on the transformed data. Also, a condensed version of the log likelihood table with the confidence interval is printed. Here are the data.
The TRANSREG procedure is run to find the Box-Cox transformation. The lambda list is -2 TO 2 BY 0.01, which produces 401 lambdas. This many power parameters makes a nice graphical display with plenty of detail around the confidence interval. However, 401 values is a lot to print, so for this reason, the usual Box-Cox transformation information table is excluded from the printed output. Instead, it is output to a SAS data set using ODS so a sample of it can be printed. Just the confidence interval and the rows corresponding to power parameters that are multiples of 0.5 are printed. Null labels are provided for the columns that need to be printed without headers. The details table is also output to a SAS data set using ODS, since it contains information that will be incorporated into some of the plots. These statements produce Output 75.6.5.

* Fit Box-Cox model, output results to output data sets;
do$ output boxcox=b details=d;
do$ exclude boxcox;
proc transreg details data=x;
   model boxcox(y / convenient lambda=-2 to 2 by 0.01) = identity(x);
   output out=trans;
run;

proc print noobs label data=b(drop=rmse);
title2 'Confidence Interval';
   where ci ne ' ' or abs(lambda - round(lambda, 0.5)) < 1e-6;
   label convenient = '00'x ci = '00'x;
run;
### Output 75.6.5.  Box-Cox Graphical Displays

</tbody>
</table>
These next steps extract information from the Box-Cox transformation and details tables and store the information in macro variables. The confidence interval limit from the details table provides a vertical axis reference line for the log likelihood plot. The convenient power parameter ('Lambda Used') is extracted from the footnote. The confidence interval is extracted from the confidence interval observations of the Box-Cox transformation table and will be used in the footnote and for horizontal axis reference lines in the log likelihood plot.

* Store values for reference lines;
  data _null_;  
    set d;  
    if description = 'CI Limit'  
      then call symput('vref', formattedvalue);  
    if description = 'Lambda Used'  
      then call symput('lambda', formattedvalue);  
  run;

  data _null_;  
  set b end=eof;  
  where ci ne ' ';
  if _n_ = 1  
    then call symput('href1', compress(put(lambda, best12.)));  
  if ci = '<'  
    then call symput('href2', compress(put(lambda, best12.)));  
  if eof  
    then call symput('href3', compress(put(lambda, best12.)));  
  run;

These steps plot the log likelihood, root mean square error and $R^2$. The input data set is the Box-Cox transformation table, which was output using ODS. These statements produce Output 75.6.6.

* Plot log likelihood, confidence interval;
  axis1 label=(angle=90 rotate=0) minor=none;
  axis2 minor=none;
  proc gplot data=b;  
    title2 'Log Likelihood';
    plot loglike * lambda / vref=&vref href=&href1 &href2 &href3  
      vaxis=axis1 haxis=axis2 frame cframe=ligr;
    footnote "Confidence Interval: &href1 - &href2 - &href3, "  
      "Lambda = &lambda";
    symbol v=none i=spline c=blue;
  run;

  footnote;
  title2 'RMSE';
  plot rmse * lambda / vaxis=axis1 haxis=axis2 frame cframe=ligr;
  run;

  title2 'R-Square';
  plot rsquare * lambda / vaxis=axis1 haxis=axis2 frame cframe=ligr;
Output 75.6.6.  Box-Cox Graphical Displays

Confidence Interval: 0.41 - 0.46 - 0.51, Lambda = 0.5
Output 75.6.6. (continued)
The optimal power parameter is 0.46, but since 0.5 is in the confidence interval, and since the CONVENIENT option was specified, the procedure chooses a square root transformation.

The next steps plot the transformation of $Y$, the original scatter plot based on the untransformed data, and the new scatter plot based on the transformed data. The results are shown in Output 75.6.7. The input data set is the ordinary output data set from PROC TRANSREG. The transformation of the variable $Y$ by default is $T_y$.

```
axis1 label=(angle=90 rotate=0) minor=none;
axis2 minor=none;
proc gplot data=trans;
title2 'Transformation';
symbol i=splines v=star c=blue;
plot ty * y / vaxis=axis1 haxis=axis2 frame cframe=ligr;
run;

title2 'Original Scatter Plot';
symbol i=none v=star c=blue;
plot y * x / vaxis=axis1 haxis=axis2 frame cframe=ligr;
run;

title2 'Transformed Scatter Plot';
symbol i=none v=star c=blue;
plot ty * x / vaxis=axis1 haxis=axis2 frame cframe=ligr;
run; quit;
```
**Output 75.6.7.** Box-Cox Graphical Displays

![Box-Cox Graphical Displays](image)

The graph displays the Box-Cox transformation of the variables, showing a near-linear relationship, indicating the effectiveness of the transformation in achieving normality or other desired properties.
Output 75.6.7. (continued)
The square root transformation makes the scatter plot essentially linear.

</table>
The TREE procedure produces a tree diagram, also known as a *dendrogram* or *phenogram*, using a data set created by the CLUSTER or VARCLUS procedure. The CLUSTER and VARCLUS procedures create output data sets that contain the results of hierarchical clustering as a tree structure. The TREE procedure uses the output data set to produce a diagram of the tree structure in the style of Johnson (1967), with the root at the top. Alternatively, the diagram can be oriented horizontally, with the root at the left. Any numeric variable in the output data set can be used to specify the heights of the clusters. PROC TREE can also create an output data set containing a variable to indicate the disjoint clusters at a specified level in the tree.

Tree diagrams are discussed in the context of cluster analysis by Duran and Odell (1974), Hartigan (1975), and Everitt (1980). Knuth (1973) provides a general treatment of tree diagrams in computer programming.

The literature on tree diagrams contains a mixture of botanical and genealogical terminology. The objects that are clustered are *leaves*. The cluster containing all objects is the *root*. A cluster containing at least two objects but not all of them is a *branch*. The general term for leaves, branches, and roots is *node*. If a cluster A is the union of clusters B and C, then A is the *parent* of B and C, and B and C are *children* of A. A leaf is thus a node with no children, and a root is a node with no parent. If every cluster has at most two children, the tree diagram is a *binary tree*. The CLUSTER procedure always produces binary trees. The VARCLUS procedure can produce tree diagrams with clusters that have many children.

### Getting Started

The TREE procedure creates tree diagrams from a SAS data set containing the tree structure. You can create this type of data set with the CLUSTER or VARCLUS procedure.

In the following example, the VARCLUS procedure is used to divide a set of variables into hierarchical clusters and to create the SAS data set containing the tree structure. The TREE procedure then generates the tree diagrams.

The following data, from Hand, et al. (1994), represent the amount of protein consumed from nine food groups for each of 25 European countries. The nine food groups are red meat (*RedMeat*), white meat (*WhiteMeat*), eggs (*Eggs*), milk (*Milk*), fish (*Fish*), cereal (*Cereal*), starch (*Starch*), nuts (*Nuts*), and fruits and vegetables (*FruVeg*).

The following SAS statements create the data set *Protein*:
data Protein;
input Country $15. RedMeat WhiteMeat Eggs Milk Fish Cereal Starch Nuts FruVeg;
datalines;
Albania 10.1 1.4 0.5 8.9 0.2 42.3 0.6 5.5 1.7

;
run;

The data set Protein contains the character variable Country and the nine numeric variables representing the food groups. The $15. in the INPUT statement specifies that the variable Country is a character variable with a length of 15.

The following statements cluster the variables in the data set Protein. The OUTFREE= option creates an output SAS data set named Tree to contain the tree structure. The CENTROID option specifies the centroid clustering method, and the MAXCLUSTERS= option specifies that the largest number of clusters desired is four. The NOPRINT option suppresses the display of the output. The VAR statement specifies that all numeric variables (RedMeat—FruVeg) are used by the procedure.

proc varclus data=Protein outtree=Tree
   centroid maxclusters=4 noprint;
   var RedMeat--FruVeg;
run;

The output data set Tree, created by the OUTFREE= option in the previous statements, contains the following variables:
_NAME_ the name of the cluster
_PARENT_ the parent of the cluster
_NCL_ the number of clusters
_VAREXP_ the amount of variance explained by the cluster
_PROPOR_ the proportion of variance explained by the clusters at the current
down level of the tree diagram
_MINPRO_ the minimum proportion of variance explained by a cluster
_MAXEIGEN_ the maximum second eigenvalue of a cluster

The following statements produce a tree diagram of the clusters created by PROC
VARCLUS:

```
proc tree data=tree ;
proc tree data=tree lineprinter;
```

PROC TREE is invoked twice. In the first invocation, the tree diagram is presented
using the default high resolution graphical output. In the second invocation, the
LINEPRINTER option specifies line printer output.

Figure 76.1 displays the default high resolution graphics version of the tree diagram.

Figure 76.2. Line Printer Graphics Version of the Tree Diagram

In both figures, the name of the cluster is displayed on the horizontal axis and the number of clusters is displayed on the vertical or height axis.

As you look up from the bottom of the figures, clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the diagram. Clusters exist at each level of the diagram. For example, at the level where the diagram indicates three clusters, the clusters are as follows:

- Cluster 1: RedMeat WhiteMeat Eggs Milk
- Cluster 2: Fish Starch
- Cluster 3: Cereal Nuts FruVeg
As you proceed up the diagram one level, the number of clusters is two. The clusters are

- Cluster 1: RedMeat WhiteMeat Eggs Milk Fish Starch
- Cluster 2: Cereal Nuts FruVeg

The following statements illustrate how you can specify the numeric variable defining the height of each node (cluster) in the tree. First, the AXIS1 statement is defined. The ORDER= option specifies the data values in the order in which they are to appear on the axis.

Next, the TREE procedure is invoked. The HORIZONTAL option orients the tree diagram horizontally. The HAXIS option specifies that the AXIS1 statement be used to customize the appearance of the horizontal axis. The HEIGHT statement specifies the variable _PROPOR_ (the proportion of variance explained) as the height variable.

```
axis1 order=(0 to 1 by 0.2);
proc tree data=Tree horizontal haxis=axis1;
  height _PROPOR_;
run;
```

![Figure 76.3. Horizontal Tree Diagram Using _PROPOR_ as the HEIGHT Variable](image)

Figure 76.3 displays the tree diagram oriented horizontally, using the variable _PROPOR_ as the height variable. As you look from left to right in the diagram,
objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the diagram.

Clusters exist at each level of the diagram, represented by horizontal line segments. Each vertical line segment represents a point where leaves and branches are connected into progressively larger clusters.

For example, three clusters are formed at the left-most point along the axis where three horizontal line segments exist. At that point, where a vertical line segment connects the Cereal-Nuts and FruVeg clusters, the proportion of variance explained is about 0.6 (PROPOR = 0.6). At the next clustering level the variables Fish and Starch are clustered with variables RedMeat through Milk, resulting in a total of two clusters. The proportion of variance explained is about 0.45 at that point.

**Syntax**

The TREE procedure is invoked by the following statements:

```
PROC TREE < options > ;
  NAME variables ;
  HEIGHT variable ;
  PARENT variables ;
  BY variables ;
  COPY variables ;
  FREQ variable ;
  ID variable ;
```

If the input data set has been created by CLUSTER or VARCLUS, the only statement required is the PROC TREE statement. The BY, COPY, FREQ, HEIGHT, ID, NAME, and PARENT statements are described after the PROC TREE statement.

**PROC TREE Statement**

```
PROC TREE < options > ;
```

The PROC TREE statement starts the TREE procedure.

The options that can appear in the PROC TREE statement are summarized in the following table.

**CFRAME=color**

specifies a color for the frame, which is the rectangle bounded by the axes.

**DATA=SAS-data-set**

specifies the input data set defining the tree. If you omit the DATA= option, the most recently created SAS data set is used.

**DESCENDING**

**DES**

reverses the sorting order for the SORT option.

**DESCRIPTION=entry-description**

specifies a description for the graph in the GOUT= catalog. The default is “Proc Tree Graph Output.”

**DISSIMILAR**

**DIS**

implies that the values of the HEIGHT variable are dissimilarities; that is, a large height value means that the clusters are very dissimilar or far apart.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.

**DOCK=n**

causes observations in the OUT= data set assigned to output clusters with a frequency of \( n \) or less to be given missing values for the output variables CLUSTER and CLUSNAME. If the NCLUSTERS= option is also specified, DOCK= also prevents clusters with a frequency of \( n \) or less from being counted toward the number of clusters requested by the NCLUSTERS= option. By default, DOCK=0.

**FILLCHAR=’c’**

**FC=’c’**

specifies the character to display between leaves that are not joined into a cluster. The character should be enclosed in single quotes. The default is a blank. The LINEPRINTER option must also be specified.

**GOUT=<libref.>member-name**

specifies the catalog in which the generated graph is stored. The default is WORK.GSEG.
**HAXIS=AXISn**
specifies the AXISn statement used to customize the appearance of the horizontal axis.

**HEIGHT=name**

**H=name**
specifies certain conventional variables to be used for the height axis of the tree diagram. For many situations, the only option you need is the HEIGHT= option. Valid values for name and their meanings are as follows:

- **HEIGHT | H** specifies the _HEIGHT_ variable.
- **LENGTH | L** defines the height of each node as its path length from the root. This can also be interpreted as the number of ancestors of the node.
- **MODE | M** specifies the _MODE_ variable.
- **NCL | N** specifies the _NCL_ (number of clusters) variable.
- **RSQ | R** specifies the _RSQ_ variable.

See also the “HEIGHT Statement” section on page 4755, which can specify any variable in the input data set to be used for the height axis. In rare cases, you may need to specify either the DISSIMILAR option or the SIMILAR option.

**HORDISPLAY=RIGHT**
specifies that the graph is to be oriented horizontally, with the leaf nodes on the right side, when the HORIZONTAL option is also specified. By default, the leaf nodes are on the left side.

**HORIZONTAL**

**HOR**

orients the tree diagram with the height axis horizontal and the root at the left. The leaf nodes are on the side specified in the HORDISPLAY= option. If you do not specify the HORIZONTAL option, the height axis is vertical, with the root at the top. When the tree takes up more than one page and is viewed on a screen, horizontal orientation can make the tree diagram considerably easier to read.

**HPAGES=n1**
specifies that the original graph is to be enlarged to cover n1 pages. If you also specify the VPAGES=n2 option, the original graph is enlarged to cover \( n1 \times n2 \) graphs. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated followed by \( 2 \times 3 = 6 \) more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

**INC=n**
specifies the increment between tick values on the height axis. If the HEIGHT variable is _NCL_, the default is usually 1, although a different value can be specified for consistency with other options. For any other HEIGHT variable, the default is some power of 10 times 1, 2, 2.5, or 5.
JOINCHAR='c'
JC='c'
specifies the character to display between leaves that are joined into a cluster. The character should be enclosed in single quotes. The default is X. The LINEPRINTER option must also be specified.

LEAFCHAR='c'
LC='c'
specifies a character to represent clusters having no children. The character should be enclosed in single quotes. The default is a period. The LINEPRINTER option must also be specified.

LEVEL=n
specifies the level of the tree defining disjoint clusters for the OUT= data set. The LEVEL= option also causes only clusters between the root and a height of n to be displayed. The clusters in the output data set are those that exist at a height of n on the tree diagram. For example, if the HEIGHT variable is _NCL_ (number of clusters) and LEVEL=5 is specified, then the OUT= data set contains five disjoint clusters. If the HEIGHT variable is _RSQ_ ($R^2$) and LEVEL=0.9 is specified, then the OUT= data set contains the smallest number of clusters that yields an $R^2$ of at least 0.9.

LINEPRINTER
specifies that the generated report is to be displayed using line printer graphics.

LINES=(<COLOR=color><WIDTH=n><DOTS>>)
enables you to specify both the color and the thickness of the lines. In addition, a dot can be drawn at each leaf node. Note that if the frame and the lines are specified to be the same color, PROC TREE selects a different color for the lines.

LIST
lists all the nodes in the tree, displaying the height, parent, and children of each node.

MAXHEIGHT=n
MAXH=n
specifies the maximum value displayed on the height axis.

MINHEIGHT=n
MINH=n
specifies the minimum value displayed on the height axis.

NAME=name
specifies the entry name for the generated graph in the GOUT= catalog. Note that each time another graph is generated with the same name, the name is modified by appending a number to make it unique.

NCLUSTERS=n
NCL=n
N=n
specifies the number of clusters desired in the OUT= data set. The number of clusters obtained may not equal the number specified if (1) there are fewer than n leaves in the tree, (2) there are more than n unconnected trees in the data set, (3) a multi-way
PROC TREE Statement ♦ 4753

tree does not contain a level with the specified number of clusters, or (4) the DOCK= option eliminates too many clusters.

The NCLUSTERS= option uses the _NCL_ variable to determine the order in which the clusters are formed. If there is no _NCL_ variable, the height variable (as determined by the HEIGHT statement or HEIGHT= option) is used instead.

**NTICK=n**
specifies the number of tick intervals on the height axis. The default depends on the values of other options.

**NOPRINT**
suppresses the display of the tree. Specify the NOPRINT option if you want only to create an OUT= data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

**OUT=SAS-data-set**
creates an output data set that contains one observation for each object in the tree or subtree being processed and variables called CLUSTER and CLUSNAME showing cluster membership at any specified level in the tree. If you specify the OUT= option, you must also specify either the NCLUSTERS= or LEVEL= option in order to define the output partition level. If you want to create a permanent SAS data set, you must specify a two-level name (refer to “SAS Data Files” in *SAS Language Reference: Concepts*).

**PAGES=n**
specifies the number of pages over which the tree diagram (from root to leaves) is to extend. The default is 1. The LINEPRINTER option must also be specified.

**POS=n**
specifies the number of column positions on the height axis. The default depends on the value of the PAGES= option, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINESIZE= options. The LINEPRINTER option must also be specified.

**ROOT='name’**
specifies the value of the NAME variable for the root of a subtree to be displayed if you do not want to display the entire tree. If you also specify the OUT= option, the output data set contains only objects belonging to the subtree specified by the ROOT= option.

**SIMILAR SIM**
implies that the values of the HEIGHT variable are similarities; that is, a large height value means that the clusters are very similar or close together.

If neither the SIMILAR nor the DISSIMILAR option is specified, PROC TREE attempts to infer from the data whether the height values are similarities or dissimilarities. If PROC TREE cannot tell this from the data, it issues an error message and does not display a tree diagram.
SORT
sorts the children of each node by the HEIGHT variable, in the order of cluster formation. See the DESCENDING option on page 4750.

SPACES=S
S=S
specifies the number of spaces between objects on the output. The default depends on the number of objects, the orientation of the tree diagram, and the values specified by the PAGESIZE= and LINESIZE= options. The LINEPRINTER option must also be specified.

TICKPOS=n
specifies the number of column positions per tick interval on the height axis. The default value is usually between 5 and 10, although a different value can be specified for consistency with other options.

TREECHAR=’c’
TC=’c’
specifies a character to represent clusters with children. The character should be enclosed in single quotes. The default is X. The LINEPRINTER option must also be specified.

VAXIS=AXISn
specifies that the AXISn statement be used to customize the appearance of the vertical axis.

VPAGES=n2
specifies that the original graph is to be enlarged to cover n2 pages. If you also specify the HPAGES=n1 option, the original graph is enlarged to cover n1 × n2 pages. For example, if HPAGES=2 and VPAGES=3, then the original graph is generated followed by 2 × 3 = 6 more graphs. In these six graphs, the original is enlarged by a factor of 2 in the horizontal direction and by a factor of 3 in the vertical direction. The graphs are generated in left-to-right and top-to-bottom order.

BY Statement

BY variables ;

You can specify a BY statement with PROC TREE to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TREE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

COPY Statement

COPY variables;

The COPY statement specifies one or more character or numeric variables to be copied to the OUT= data set.

FREQ Statement

FREQ variables;

The FREQ statement specifies one numeric variable that tells how many clustering observations belong to the cluster. If the FREQ statement is omitted, PROC TREE looks for a variable called _FREQ_ to specify the number of observations per cluster. If neither the FREQ statement nor the _FREQ_ variable is present, each leaf is assumed to represent one clustering observation, and the frequency for each internal node is found by summing the frequencies of its children.

HEIGHT Statement

HEIGHT variable;

The HEIGHT statement specifies the name of a numeric variable to define the height of each node (cluster) in the tree. If the data set does not contain _HEIGHT_, the height of each node is defined to be its path length from the root.

ID Statement

ID variables;

The ID variable is used to identify the objects (leaves) in the tree on the output. The ID variable can be a character or numeric variable of any length. If the ID statement is omitted, the variable in the NAME statement is used instead. If both the ID and NAME statements are omitted, PROC TREE looks for a variable called _NAME_. If the _NAME_ variable is not found in the data set, PROC TREE issues an error message and stops. The ID variable is copied to the OUT= data set.
**NAME Statement**

```
NAME variables ;
```

The NAME statement specifies a character or numeric variable identifying the node represented by each observation. The NAME variable and the PARENT variable jointly define the tree structure. If the NAME statement is omitted, PROC TREE looks for a variable called _NAME_. If the _NAME_ variable is not found in the data set, PROC TREE issues an error message and stops.

**PARENT Statement**

```
PARENT variables ;
```

The PARENT statement specifies a character or numeric variable identifying the node in the tree that is the parent of each observation. The PARENT variable must have the same formatted length as the NAME variable. If the PARENT statement is omitted, PROC TREE looks for a variable called _PARENT_. If the _PARENT_ variable is not found in the data set, PROC TREE issues an error message and stops.

**Details**

**Missing Values**

An observation with a missing value for the NAME variable is omitted from processing. If the PARENT variable has a missing value but the NAME variable is present, the observation is treated as the root of a tree. A data set can contain several roots and, hence, several trees.

Missing values of the HEIGHT variable are set to upper or lower bounds determined from the nonmissing values under the assumption that the heights are monotonic with respect to the tree structure.

Missing values of the FREQ variable are inferred from nonmissing values where possible; otherwise, they are treated as zero.

**Output Data Set**

The OUT= data set contains one observation for each leaf in the tree or subtree being processed. The variables are as follows:

- the BY variables, if any
- the ID variable, or the NAME variable if the ID statement is not used
- the COPY variables
- a numeric variable CLUSTER taking values from 1 to c, where c is the number of disjoint clusters. The cluster to which the first observation belongs is given the number 1, the cluster to which the next observation belongs that does not belong to cluster 1 is given the number 2, and so on.
- a character variable **CLUSNAME** giving the value of the NAME variable of the cluster to which the observation belongs

The **CLUSTER** and **CLUSNAME** variables are missing if the corresponding leaf has a nonpositive frequency.

**Displayed Output**

The displayed output from the TREE procedure includes the following:

- the names of the objects in the tree
- the height axis
- the tree diagram. A high-resolution graphics tree diagram is produced on the graphics device. The leaves are displayed at the bottom of the graph. Horizontal lines connect the leaves into branches, while the topmost horizontal line indicates the root.

If the LINEPRINTER option is specified, the root (the cluster containing all the objects) is indicated by a solid line of the character specified by the **TREECHAR=** option (the default character is ‘X’). At each level of the tree, clusters are shown by unbroken lines of the **TREECHAR=** symbol with the **FILLCHAR=** symbol (the default is a blank) separating the clusters. The **LEAFCHAR=** symbol (the default character is a period) represents single-member clusters.

By default, the tree diagram is oriented with the height axis vertical and the object names at the top of the diagram. If the HORIZONTAL option is specified, then the height axis is horizontal and the object names are on the left.

**ODS Table Names**

PROC TREE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**Table 76.2. ODS Tables Produced in PROC TREE**

Examples

Example 76.1. Mammals’ Teeth

The following data give the numbers of different kinds of teeth for a variety of mammals. The mammals are clustered by average linkage using the CLUSTER procedure (Output 76.1.1). The PROC TREE statement uses the average-linkage distance as the height axis, which is the default, and creates a horizontal high-resolution graphics tree (Output 76.1.2).

```sas
data teeth;
  title 'Mammals’ Teeth';
  input mammal $ 1-16 @21 (v1-v8) (1.);
  label v1='Right Top Incisors'
        v2='Right Bottom Incisors'
        v3='Right Top Canines'
        v4='Right Bottom Canines'
        v5='Right Top Premolars'
        v6='Right Bottom Premolars'
        v7='Right Top Molars'
        v8='Right Bottom Molars';
  datalines;
  Brown Bat 23113333
  Mole 32103333
  Silver Hair Bat 23112333
  Pigmy Bat 23112233

  Marten 33114412
  Weasel 33113312
  Wolverine 33114412
  Badger 33113312
  River Otter 33114312
  Sea Otter 32113312
  Jaguar 33113211
  Cougar 33113211
  Fur Seal 32114411
  Sea Lion 32114411
  Grey Seal 32113322
  Elephant Seal 21114411
  Reindeer 04103333
  Elk 04103333
  Deer 04003333
```

Example 76.1. Mammals’ Teeth

```plaintext
Moose
;
'options pagesize=60 linesize=110;

proc cluster method=average std pseudo noeigen outtree=tree;
   id mammal;
   var v1-v8;
run;

proc tree graphics horizontal;
run;
```

Output 76.1.1 displays the information on how the clusters are joined. For example, the cluster history shows that the observations Wolf and Bear form cluster 29, which is merged with Raccoon to form cluster 11.

</tbody>
</table>
```
As you look from left-to-right in the diagram in Output 76.1.2, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the diagram. Clusters exist at each level of the diagram, and every vertical line connects leaves and branches into progressively larger clusters. For example, the five bats form a cluster at the 0.6 level, while the next cluster consists only of the mole. The observations Reindeer, Elk, Deer, and Moose form the next cluster at the 0.6 level, the mammals Pika through House Mouse are in the fourth cluster. The observations Wolf, Bear, and Raccoon form the fifth cluster, while the last cluster contains the observations Marten through Elephant Seal.

The following statements create the same tree with line printer graphics in a vertical orientation; the tree is displayed in Output 76.1.3.

```
proc tree lineprinter;
run;
```
As you look up from the bottom of the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the top (or root) of the diagram. Clusters exist at each level of the diagram. For example, the unbroken line of Xs at the left-most side of the 0.6 level indicates that the five bats have formed a cluster. The next cluster is represented by a period because it contains only one mammal, Mole. Reindeer, Elk, Deer, and Moose form the next cluster, indicated by Xs again. The mammals Pika through House Mouse are in the fourth cluster. The observations Wolf, Bear, and Raccoon form the fifth cluster, while the last cluster contains the observations Marten through Elephant Seal.

The next statement sorts the clusters at each branch in order of formation and uses the number of clusters as the height axis. The resulting tree is displayed in Output 76.1.4.

```plaintext
proc tree sort height=n horizontal;
run;
```
Output 76.1.4. PROC TREE with SORT and HEIGHT= Options

Because the CLUSTER procedure always produces binary trees, the number of internal (root and branch) nodes in the tree is one less than the number of leaves. Therefore 31 clusters are formed from the 32 mammals in the input data set. These are represented by the 31 vertical line segments in the tree diagram, each at a different value along the horizontal axis.

As you examine the tree from left to right, the first vertical line segment is where Beaver and Groundhog are clustered and the number of clusters is 31. The next cluster is formed from Gray Squirrel and Porcupine. The third contains Wolf and Bear. Note how the tree graphically displays the clustering order information that was presented in tabular form by the CLUSTER procedure in Output 76.1.1.

The same clusters as in Output 76.1.2 and Output 76.1.3 can be seen at the six-cluster level of the tree diagram in Output 76.1.4, although the SORT and HEIGHT= options make them appear in a different order.

The following statements create these six clusters and display them in Output 76.1.5. The PROC TREE statement produces no output but creates an output data set indicating the cluster to which each observation belongs at the six-cluster level in the tree.
### Example 76.1. Mammals' Teeth

```
proc tree noprint out=part nclusters=6;
  id mammal;
  copy v1-v8;
proc sort;
  by cluster;
proc print label uniform;
  id mammal;
  var v1-v8;
  format v1-v8 1.;
  by cluster;
run;
```

Example 76.2. Iris Data

Fisher’s (1936) iris data gives sepal and petal dimensions for three different species of iris. The data are clustered by kth-nearest-neighbor density linkage using the CLUSTER procedure with K=8. Observations are identified by species (Setosa, Versicolor or Virginica) in the tree diagram, which is oriented with the height axis horizontal. The following statements produce Output 76.2.1 and Output 76.2.2.

```plaintext
proc format;
  value specname
    1='Setosa'
    2='Versicolor'
    3='Virginica';
run;

data iris;
  title 'Fisher (1936) Iris Data';
  input SepalLength SepalWidth PetalLength PetalWidth Species @@;
  format Species specname.;
  label SepalLength='Sepal Length in mm.'
     SepalWidth='Sepal Width in mm.'
     PetalLength='Petal Length in mm.'
     PetalWidth='Petal Width in mm.';
  symbol = put(species, specname10.);

Chapter 77
The TTEST Procedure

Overview

The TTEST procedure performs \( t \) tests for one sample, two samples, and paired observations. The one-sample \( t \) test compares the mean of the sample to a given number. The two-sample \( t \) test compares the mean of the first sample minus the mean of the second sample to a given number. The paired observations \( t \) test compares the mean of the differences in the observations to a given number.

For one-sample tests, PROC TTEST computes the sample mean of the variable and compares it with a given number. Paired comparisons use the one sample process on the differences between the observations. Paired comparisons can be made between many pairs of variables with one call to PROC TTEST. For group comparisons, PROC TTEST computes sample means for each of two groups of observations and tests the hypothesis that the population means differ by a given amount. This latter analysis can be considered a special case of a one-way analysis of variance with two levels of classification.

The underlying assumption of the \( t \) test in all three cases is that the observations are random samples drawn from normally distributed populations. This assumption can be checked using the UNIVARIATE procedure; if the normality assumptions for the \( t \) test are not satisfied, you should analyze your data using the NPAR1WAY procedure. The two populations of a group comparison must also be independent. If they are not independent, you should question the validity of a paired comparison.

PROC TTEST computes the group comparison \( t \) statistic based on the assumption that the variances of the two groups are equal. It also computes an approximate \( t \) based on the assumption that the variances are unequal (the Behrens-Fisher problem). The degrees of freedom and probability level are given for each; Satterthwaite’s (1946) approximation is used to compute the degrees of freedom associated with the approximate \( t \). In addition, you can request the Cochran and Cox (1950) approximation of the probability level for the approximate \( t \). The folded form of the \( F \) statistic is computed to test for equality of the two variances (Steel and Torrie 1980).

FREQ and WEIGHT statements are available. Data can be input in the form of observations or summary statistics. Summary statistics and their confidence intervals, and differences of means are output. For two-sample tests, the pooled-variance and a test for equality of variances are also produced.
Getting Started

One-Sample \( t \) Test

A one-sample \( t \) test can be used to compare a sample mean to a given value. This example, taken from Huntsberger and Billingsley (1989, p. 290), tests whether the mean length of a certain type of court case is 80 days using 20 randomly chosen cases. The data are read by the following DATA step:

```plaintext
title 'One-Sample t Test';
data time;
    input time @@;
datalines;
43 90 84 87 116 95 86 99 93 92
121 71 66 98 79 102 60 112 105 98;
run;
```

The only variable in the data set, `time`, is assumed to be normally distributed. The trailing at signs (@@) indicate that there is more than one observation on a line. The following code invokes PROC TTEST for a one-sample \( t \) test:

```plaintext
proc ttest h0=80 alpha=0.1;
    var time;
run;
```

The VAR statement indicates that the `time` variable is being studied, while the H0= option specifies that the mean of the `time` variable should be compared to the value 80 rather than the default null hypothesis of 0. This ALPHA= option requests 10% confidence intervals rather than the default 5% confidence intervals. The output is displayed in Figure 77.1.

```

| time     | 19 | 2.30    | 0.0329|
```

**Figure 77.1.** One-Sample \( t \) Test Results

Summary statistics appear at the top of the output. The sample size \( (N) \), the mean and its confidence bounds (Lower CL Mean and Upper CL Mean), the standard deviation
Comparing Group Means

If you want to compare values obtained from two different groups, and if the groups are independent of each other and the data are normally distributed in each group, then a group $t$ test can be used. Examples of such group comparisons include

- test scores for two third-grade classes, where one of the classes receives tutoring
- fuel efficiency readings of two automobile nameplates, where each nameplate uses the same fuel
- sunburn scores for two sunblock lotions, each applied to a different group of people
- political attitude scores of males and females

In the following example, the golf scores for males and females in a physical education class are compared. The sample sizes from each population are equal, but this is not required for further analysis. The data are read by the following statements:

```plaintext
title 'Comparing Group Means'; data scores;   input Gender $ Score @@; datalines; f 75 f 76 f 80 f 77 f 80 f 77 f 73 m 82 m 80 m 85 m 85 m 78 m 87 m 82 ; run;
```

The dollar sign ($) following Gender in the INPUT statement indicates that Gender is a character variable. The trailing at signs (@@) enable the procedure to read more than one observation per line.

You can use a group $t$ test to determine if the mean golf score for the men in the class differs significantly from the mean score for the women. If you also suspect that the distributions of the golf scores of males and females have unequal variances, then submitting the following statements invokes PROC TTEST with options to deal with the unequal variance case.

```plaintext
proc ttest cochran ci=equal umpu;
   class Gender;
   var Score;
run;
```
The CLASS statement contains the variable that distinguishes the groups being compared, and the VAR statement specifies the response variable to be used in calculations. The COCHRAN option produces \( p \)-values for the unequal variance situation using the Cochran and Cox(1950) approximation. Equal tailed and uniformly most powerful unbiased (UMPU) confidence intervals for \( \sigma \) are requested by the CI= option. Output from these statements is displayed in Figure 77.2 through Figure 77.4.

### Simple Statistics

Simple statistics for the two populations being compared, as well as for the difference of the means between the populations, are displayed in Figure 77.2. The Variable column denotes the response variable, while the Class column indicates the population corresponding to the statistics in that row. The sample size (N) for each population, the sample means (Mean), and lower and upper confidence bounds for the means (Lower CL Mean and Upper CL Mean) are displayed next. The standard deviations (Std Dev) are displayed as well, with equal tailed confidence bounds in the Lower CL Std Dev and Upper CL Std Dev columns and UMPU confidence bounds in the UMPU Upper CL Std Dev and UMPU Lower CL Std Dev columns. In addition, standard error of the mean and the minimum and maximum data values are displayed.

### T-Tests

<table>
<thead>

<td>0.0087</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The test statistics, associated degrees of freedom, and \( p \)-values are displayed in Figure 77.3. The Method column denotes which \( t \) test is being used for that row, and the Variances column indicates what assumption about variances is being made. The pooled test assumes that the two populations have equal variances and uses degrees of freedom \( n_1 + n_2 - 2 \), where \( n_1 \) and \( n_2 \) are the sample sizes for the two populations. The remaining two tests do not assume that the populations have equal variances. The Satterthwaite test uses the Satterthwaite approximation for degrees of freedom, while the Cochran test uses the Cochran and Cox approximation for the \( p \)-value.

<table>
<thead>
<tr>
<th>Equality of Variances</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable</strong></td>
</tr>
<tr>
<td>Score</td>
</tr>
</tbody>
</table>

**Figure 77.4.** Tests of Equality of Variances

Examine the output in Figure 77.4 to determine which \( t \) test is appropriate. The “Equality of Variances” test results show that the assumption of equal variances is reasonable for these data (the Folded F statistic \( F' = 1.53 \), with \( p = 0.6189 \)). If the assumption of normality is also reasonable, the appropriate test is the usual pooled \( t \) test, which shows that the average golf scores for men and women are significantly different (\( t = -3.83, p = 0.0024 \)). If the assumption of equality of variances is not reasonable, then either the Satterthwaite or the Cochran test should be used.

The assumption of normality can be checked using PROC UNIVARIATE; if the assumption of normality is not reasonable, you should analyze the data with the non-parametric Wilcoxon Rank Sum test using PROC NPAR1WAY.

### Syntax

The following statements are available in PROC TTEST.

```
PROC TTEST < options > ;
  CLASS variable ;
  PAIRED variables ;
  BY variables ;
  VAR variables ;
  FREQ variable ;
  WEIGHT variable ;
```

No statement can be used more than once. There is no restriction on the order of the statements after the PROC statement.
PROC TTEST Statement

PROC TTEST < options > ;

The following options can appear in the PROC TTEST statement.

**ALPHA=p**

specifies that confidence intervals are to be $100(1-p)\%$ confidence intervals, where $0 < p < 1$. By default, PROC TTEST uses ALPHA=0.05. If $p$ is 0 or less, or 1 or more, an error message is printed.

**CI=EQUAL**

**CI=UMPU**

**CI=NONE**

specifies whether a confidence interval is displayed for $\sigma$ and, if so, what kind. The CI=EQUAL option specifies an equal tailed confidence interval, and it is the default. The CI=UMPU option specifies an interval based on the uniformly most powerful unbiased test of $H_0: \sigma = \sigma_0$. The CI=NONE option requests that no confidence interval be displayed for $\sigma$. The values EQUAL and UMPU together request that both types of confidence intervals be displayed. If the value NONE is specified with one or both of the values EQUAL and UMPU, NONE takes precedence. For more information, see the “Confidence Interval Estimation” section on page 4785.

**COCHRAN**

requests the Cochran and Cox (1950) approximation of the probability level of the approximate $t$ statistic for the unequal variances situation.

**DATA=SAS-data-set**

names the SAS data set for the procedure to use. By default, PROC TTEST uses the most recently created SAS data set. The input data set can contain summary statistics of the observations instead of the observations themselves. The number, mean, and standard deviation of the observations are required for each BY group (one sample and paired differences) or for each class within each BY group (two samples). For more information on the DATA= option, see the “Input Data Set of Statistics” section on page 4783.

**H0=m**

requests tests against $m$ instead of 0 in all three situations (one-sample, two-sample, and paired observation $t$ tests). By default, PROC TTEST uses H0=0.

**BY Statement**

BY variables ;

You can specify a BY statement with PROC TTEST to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
• Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the TTEST procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

• Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the SAS Procedures Guide.

CLASS Statement

CLASS variable;

A CLASS statement giving the name of the classification (or grouping) variable must accompany the PROC TTEST statement in the two independent sample cases. It should be omitted for the one sample or paired comparison situations. If it is used without the VAR statement, all numeric variables in the input data set (except those appearing in the CLASS, BY, FREQ, or WEIGHT statement) are included in the analysis.

The class variable must have two, and only two, levels. PROC TTEST divides the observations into the two groups for the t test using the levels of this variable. You can use either a numeric or a character variable in the CLASS statement.

Class levels are determined from the formatted values of the CLASS variable. Thus, you can use formats to define group levels. Refer to the discussions of the FORMAT procedure, the FORMAT statement, formats, and informats in SAS Language Reference: Dictionary.

FREQ Statement

FREQ variable;

The variable in the FREQ statement identifies a variable that contains the frequency of occurrence of each observation. PROC TTEST treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If the value is not an integer, only the integer portion is used. If the frequency value is less than 1 or is missing, the observation is not used in the analysis. When the FREQ statement is not specified, each observation is assigned a frequency of 1. The FREQ statement cannot be used if the DATA= data set contains statistics instead of the original observations.
PAIRED Statement

**PAIRED** *PairLists* ;

The *PairLists* in the PAIRED statement identifies the variables to be compared in paired comparisons. You can use one or more *PairLists*. Variables or lists of variables are separated by an asterisk (*) or a colon (:). The asterisk requests comparisons between each variable on the left with each variable on the right. The colon requests comparisons between the first variable on the left and the first on the right, the second on the left and the second on the right, and so forth. The number of variables on the left must equal the number on the right when the colon is used. The differences are calculated by taking the variable on the left minus the variable on the right for both the asterisk and colon. A pair formed by a variable with itself is ignored. Use the PAIRED statement only for paired comparisons. The CLASS and VAR statements cannot be used with the PAIRED statement.

Examples of the use of the asterisk and the colon are shown in the following table.

<table>
<thead>
<tr>
<th>These PAIRED statements...</th>
<th>yield these comparisons</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAIRED A*B;</td>
<td>A-B</td>
</tr>
<tr>
<td>PAIRED A<em>B C</em>D;</td>

</tr>
<tr>
<td>PAIRED (A B) * (C D);</td>
<td>A-C, A-D, B-C, and B-D</td>
</tr>
<tr>
<td>PAIRED (A B) * (C B);</td>
<td>A-C, A-B, and B-C</td>
</tr>
<tr>
<td>PAIRED (A1-A2) : (B1-B2);</td>
<td>A1-B1 and A2-B2</td>
</tr>
</tbody>
</table>

VAR Statement

**VAR** *variables* ;

The VAR statement names the variables to be used in the analyses. One-sample comparisons are conducted when the VAR statement is used without the CLASS statement, while group comparisons are conducted when the VAR statement is used with a CLASS statement. If the VAR statement is omitted, all numeric variables in the input data set (except a numeric variable appearing in the BY, CLASS, FREQ, or WEIGHT statement) are included in the analysis. The VAR statement can be used with one- and two-sample *t* tests and cannot be used with the PAIRED statement.
WEIGHT Statement

WEIGHT variable;

The WEIGHT statement weights each observation in the input data set by the value of the WEIGHT variable. The values of the WEIGHT variable can be nonintegral, and they are not truncated. Observations with negative, zero, or missing values for the WEIGHT variable are not used in the analyses. Each observation is assigned a weight of 1 when the WEIGHT statement is not used. The WEIGHT statement cannot be used with an input data set of summary statistics.

Details

Input Data Set of Statistics

PROC TTEST accepts data containing either observation values or summary statistics. It assumes that the DATA= data set contains statistics if it contains a character variable with name _TYPE_ or _STAT_. The TTEST procedure expects this character variable to contain the names of statistics. If both _TYPE_ and _STAT_ variables exist and are of type character, PROC TTEST expects _TYPE_ to contain the names of statistics including ‘N’, ‘MEAN’, and ‘STD’ for each BY group (or for each class within each BY group for two-sample t tests). If no ‘N’, ‘MEAN’, or ‘STD’ statistics exist, an error message is printed.

FREQ, WEIGHT, and PAIRED statements cannot be used with input data sets of statistics. BY, CLASS, and VAR statements are the same regardless of data set type. For paired comparisons, see the _DIF_ values for the _TYPE_=T observations in output produced by the OUTSTATS= option in the PROC COMPARE statement (refer to the SAS Procedures Guide).

Missing Values

An observation is omitted from the calculations if it has a missing value for either the CLASS variable, a PAIRED variable, or the variable to be tested. If more than one variable is listed in the VAR statement, a missing value in one variable does not eliminate the observation from the analysis of other nonmissing variables.

Computational Methods

The t Statistic

The form of the t statistic used varies with the type of test being performed.

- To compare an individual mean with a sample of size $n$ to a value $m$, use

$$ t = \frac{\bar{x} - m}{s/\sqrt{n}} $$

where $\bar{x}$ is the sample mean of the observations and $s^2$ is the sample variance of the observations.
• To compare \( n \) paired differences to a value \( m \), use

\[
t = \frac{\bar{d} - m}{s_d/\sqrt{n}}
\]

where \( \bar{d} \) is the sample mean of the paired differences and \( s_d^2 \) is the sample variance of the paired differences.

• To compare means from two independent samples with \( n_1 \) and \( n_2 \) observations to a value \( m \), use

\[
t = \frac{(\bar{x}_1 - \bar{x}_2) - m}{s \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}
\]

where \( s^2 \) is the pooled variance

\[
s^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}
\]

and \( s_1^2 \) and \( s_2^2 \) are the sample variances of the two groups. The use of this \( t \) statistic depends on the assumption that \( \sigma_1^2 = \sigma_2^2 \), where \( \sigma_1^2 \) and \( \sigma_2^2 \) are the population variances of the two groups.

**The Folded Form F Statistic**

The folded form of the \( F \) statistic, \( F' \), tests the hypothesis that the variances are equal, where

\[
F' = \frac{\max(s_1^2, s_2^2)}{\min(s_1^2, s_2^2)}
\]

A test of \( F' \) is a two-tailed \( F \) test because you do not specify which variance you expect to be larger. The \( p \)-value gives the probability of a greater \( F \) value under the null hypothesis that \( \sigma_1^2 = \sigma_2^2 \).

**The Approximate t Statistic**

Under the assumption of unequal variances, the approximate \( t \) statistic is computed as

\[
t' = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{w_1 + w_2}}
\]

where

\[
w_1 = \frac{s_1^2}{n_1}, \quad w_2 = \frac{s_2^2}{n_2}
\]
The Cochran and Cox Approximation

The Cochran and Cox (1950) approximation of the probability level of the approximate $t$ statistic is the value of $p$ such that

$$t' = \frac{w_1 t_1 + w_2 t_2}{w_1 + w_2}$$

where $t_1$ and $t_2$ are the critical values of the $t$ distribution corresponding to a significance level of $p$ and sample sizes of $n_1$ and $n_2$, respectively. The number of degrees of freedom is undefined when $n_1 \neq n_2$. In general, the Cochran and Cox test tends to be conservative (Lee and Gurland 1975).

Satterthwaite’s Approximation

The formula for Satterthwaite’s (1946) approximation for the degrees of freedom for the approximate $t$ statistic is:

$$df = \frac{(w_1 + w_2)^2}{\left(\frac{w_1^2}{n_1 - 1} + \frac{w_2^2}{n_2 - 1}\right)}$$

Refer to Steel and Torrie (1980) or Freund, Littell, and Spector (1986) for more information.

Confidence Interval Estimation

The form of the confidence interval varies with the statistic for which it is computed. In the following confidence intervals involving means, $t_{1-\frac{\alpha}{2},n-1}$ is the $100(1 - \frac{\alpha}{2})\%$ quantile of the $t$ distribution with $n - 1$ degrees of freedom. The confidence interval for

- an individual mean from a sample of size $n$ compared to a value $m$ is given by
  $$\bar{x} - m \pm t_{1-\frac{\alpha}{2},n-1} \frac{s}{\sqrt{n}}$$
  where $\bar{x}$ is the sample mean of the observations and $s^2$ is the sample variance of the observations

- paired differences with a sample of size $n$ differences compared to a value $m$ is given by
  $$(\bar{d} - m) \pm t_{1-\frac{\alpha}{2},n-1} \frac{s_d}{\sqrt{n}}$$
  where $\bar{d}$ and $s_d^2$ are the sample mean and sample variance of the paired differences, respectively
the difference of two means from independent samples with \( n_1 \) and \( n_2 \) observations compared to a value \( m \) is given by

\[
(\bar{x}_1 - \bar{x}_2) - m \pm t_{1-\frac{\alpha}{2}, n_1+n_2-2} s \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}
\]

where \( s^2 \) is the pooled variance

\[
s^2 = \frac{(n_1 - 1)s^2_1 + (n_2 - 1)s^2_2}{n_1 + n_2 - 2}
\]

and where \( s^2_1 \) and \( s^2_2 \) are the sample variances of the two groups. The use of this confidence interval depends on the assumption that \( \sigma^2_1 = \sigma^2_2 \), where \( \sigma^2_1 \) and \( \sigma^2_2 \) are the population variances of the two groups.

The distribution of the estimated standard deviation of a mean is not symmetric, so alternative methods of estimating confidence intervals are possible. PROC TTEST computes two estimates. For both methods, the data are assumed to have a normal distribution with mean \( \mu \) and variance \( \sigma^2 \), both unknown. The methods are as follows:

- The default method, an equal-tails confidence interval, puts an equal amount of area \( (\frac{\alpha}{2}) \) in each tail of the chi-square distribution. An equal tails test of \( H_0: \sigma = \sigma_0 \) has acceptance region

\[
\left\{ \chi^2_{1-\frac{\alpha}{2}, n-1} \leq \frac{(n - 1)S^2}{\sigma_0^2} \leq \chi^2_{\frac{\alpha}{2}, n-1} \right\}
\]

which can be algebraically manipulated to give the following 100(1 - \( \alpha \))% confidence interval for \( \sigma^2 \):

\[
\left( \frac{(n - 1)S^2}{\chi^2_{1-\frac{\alpha}{2}, n-1}}, \frac{(n - 1)S^2}{\chi^2_{\frac{\alpha}{2}, n-1}} \right)
\]

In order to obtain a confidence interval for \( \sigma \), the square root of each side is taken, leading to the following 100(1 - \( \alpha \))% confidence interval:

\[
\left( \sqrt{\frac{(n - 1)S^2}{\chi^2_{1-\frac{\alpha}{2}, n-1}}}, \sqrt{\frac{(n - 1)S^2}{\chi^2_{\frac{\alpha}{2}, n-1}}} \right)
\]

- The second method yields a confidence interval derived from the uniformly most powerful unbiased test of \( H_0: \sigma = \sigma_0 \) (Lehmann 1986). This test has acceptance region

\[
\left\{ c_1 \leq \frac{(n - 1)S^2}{\sigma_0^2} \leq c_2 \right\}
\]

where the critical values \( c_1 \) and \( c_2 \) satisfy

\[
\int_{c_1}^{c_2} f_n(y)dy = 1 - \alpha
\]
and
\[ \int_{c_1}^{c_2} y f_n(y) dy = n(1 - \alpha) \]

where \( f_n(y) \) is the chi-squared distribution with \( n \) degrees of freedom. This acceptance region can be algebraically manipulated to arrive at
\[ P \left\{ \frac{(n - 1)S^2}{c_2} \leq \sigma^2 \leq \frac{(n - 1)S^2}{c_1} \right\} = 1 - \alpha \]

where \( c_1 \) and \( c_2 \) solve the preceding two integrals. To find the area in each tail of the chi-square distribution to which these two critical values correspond, solve \( c_1 = \chi^2_{1 - \alpha, n-1} \) and \( c_2 = \chi^2_{\alpha_1, n-1} \) for \( \alpha_1 \) and \( \alpha_2 \); the resulting \( \alpha_1 \) and \( \alpha_2 \) sum to \( \alpha \). Hence, a \( 100(1 - \alpha)\% \) confidence interval for \( \sigma^2 \) is given by
\[ \left( \frac{(n - 1)S^2}{\chi^2_{1 - \alpha_2, n-1}}, \frac{(n - 1)S^2}{\chi^2_{\alpha_1, n-1}} \right) \]

In order to obtain a \( 100(1 - \alpha)\% \) confidence interval for \( \sigma \), the square root is taken of both terms, yielding
\[ \left( \sqrt{\frac{(n - 1)S^2}{\chi^2_{1 - \alpha_2, n-1}}}, \sqrt{\frac{(n - 1)S^2}{\chi^2_{\alpha_1, n-1}}} \right) \]

**Displayed Output**

For each variable in the analysis, the TTEST procedure displays the following summary statistics for each group:

- the name of the dependent variable
- the levels of the classification variable
- \( N \), the number of nonmissing values
- Lower CL Mean, the lower confidence bound for the mean
- the Mean or average
- Upper CL Mean, the upper confidence bound for the mean
- Lower CL Std Dev, the lower confidence bound for the standard deviation
- Std Dev, the standard deviation
- Upper CL Std Dev, the upper confidence bound for the standard deviation
- Std Err, the standard error of the mean
- the Minimum value, if the line size allows
- the Maximum value, if the line size allows
- upper and lower UMPU confidence bounds for the standard deviation, displayed if the CI=UMPU option is specified in the PROC TTEST statement
Next, the results of several $t$ tests are given. For one-sample and paired observations $t$ tests, the TTEST procedure displays

- $t$ Value, the $t$ statistic for testing the null hypothesis that the mean of the group is zero
- DF, the degrees of freedom
- $Pr > |t|$, the probability of a greater absolute value of $t$ under the null hypothesis. This is the two-tailed significance probability.

To compute the one-tailed significance probability, first determine whether large values of $t$ are significant or small values are. Let $p$ denote the significance probability for the two-tailed test. If large values of $t$ are significant, then the one-tailed probability is $p/2$ if $t \geq 0$, and is $1 - p/2$ if $t < 0$. If small values of $t$ are significant, then the one-tailed probability is $1 - p/2$ if $t \geq 0$, and is $p/2$ if $t < 0$.

For two-sample $t$ tests, the TTEST procedure displays all the items in the following list. You need to decide whether equal or unequal variances are appropriate for your data.

- Under the assumption of unequal variances, the TTEST procedure displays results using Satterthwaite’s method. If the COCHRAN option is specified, the results for the Cochran and Cox approximation are also displayed.
  - $t$ Value, an approximate $t$ statistic for testing the null hypothesis that the means of the two groups are equal
  - DF, the approximate degrees of freedom
  - $Pr > |t|$, the probability of a greater absolute value of $t$ under the null hypothesis. This is the two-tailed significance probability. The one-tailed probability is computed the same way as in a one-sample $t$ test.

- Under the assumption of equal variances, the TTEST procedure displays results obtained by pooling the group variances.
  - $t$ Value, the $t$ statistic for testing the null hypothesis that the means of the two groups are equal
  - DF, the degrees of freedom
  - $Pr > |t|$, the probability of a greater absolute value of $t$ under the null hypothesis. This is the two-tailed significance probability. The one-tailed probability is computed the same way as in a one-sample $t$ test.

- PROC TTEST then gives the results of the test of equality of variances:
  - the $F'$ (folded) statistic (see the “The Folded Form F Statistic” section on page 4784)
  - Num DF and Den DF, the numerator and denominator degrees of freedom in each group
  - $Pr > F$, the probability of a greater $F'$ value. This is the two-tailed significance probability.
ODS Table Names

PROC TTEST assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Examples

Example 77.1. Comparing Group Means Using Input Data Set of Summary Statistics

The following example, taken from Huntsberger and Billingsley (1989), compares two grazing methods using 32 steer. Half of the steer are allowed to graze continuously while the other half are subjected to controlled grazing time. The researchers want to know if these two grazing methods impact weight gain differently. The data are read by the following DATA step.

```sas
Title 'Group Comparison Using Input Data Set of Summary Statistics';

Data graze;
   Length GrazeType $ 10;
   Input GrazeType $ WtGain @@;
   DataLines;
   Controlled 45  Controlled 62
   Controlled 96  Controlled 128
   Controlled 120 Controlled 99
   Controlled 28  Controlled 50
   Controlled 109 Controlled 115
   Controlled 39  Controlled 96
   Controlled 87  Controlled 100
   Controlled 76  Controlled 80
   Continuous 94  Continuous 12
   Continuous 26  Continuous 89
   Continuous 88  Continuous 96
   Continuous 85  Continuous 130
   Continuous 75  Continuous 54
   Continuous 112 Continuous 69
   Continuous 104 Continuous 95
   Continuous 53  Continuous 21
; Run;
```

The variable GrazeType denotes the grazing method: ‘controlled’ is controlled grazing and ‘continuous’ is continuous grazing. The dollar sign ($) following GrazeType makes it a character variable, and the trailing at signs (@@) tell the procedure that
there is more than one observation per line. The MEANS procedure is invoked to create a data set of summary statistics with the following statements:

```plaintext
proc sort;
   by GrazeType;
proc means data=graze noprint;
   var WtGain;
   by GrazeType;
   output out=newgraze;
run;
```

The NOPRINT option eliminates all output from the MEANS procedure. The VAR statement tells PROC MEANS to compute summary statistics for the WtGain variable, and the BY statement requests a separate set of summary statistics for each level of GrazeType. The OUTPUT OUT= statement tells PROC MEANS to put the summary statistics into a data set called newgraze so that it may be used in subsequent procedures. This new data set is displayed in Output 77.1.1 by using PROC PRINT as follows:

```plaintext
proc print data=newgraze;
run;
```

The _STAT_ variable contains the names of the statistics, and the GrazeType variable indicates which group the statistic is from.

**Output 77.1.1. Output Data Set of Summary Statistics**

The following code invokes PROC TTEST using the newgraze data set, as denoted by the DATA= option.

```plaintext
proc ttest data=newgraze;
   class GrazeType;
   var WtGain;
run;
```
The CLASS statement contains the variable that distinguishes between the groups being compared, in this case GrazeType. The summary statistics and confidence intervals are displayed first, as shown in Output 77.1.2.

### Output 77.1.2. Summary Statistics

</tr>
</tbody>
</table>
```

In Output 77.1.2, the Variable column states the variable used in computations and the Class column specifies the group for which the statistics are computed. For each class, the sample size, mean, standard deviation and standard error, and maximum and minimum values are displayed. The confidence bounds for the mean are also displayed; however, since summary statistics are used as input, the confidence bounds for the standard deviation of the groups are not calculated.

### Output 77.1.3. t Tests

```
<table>
<thead>

<tr>
<td>WtGain</td>
<td>Folded F</td>
<td>15</td>
<td>15</td>
<td>1.23</td>
<td>0.6981</td>
</tr>
</tbody>
</table>
```

Output 77.1.3 shows the results of tests for equal group means and equal variances. A group test statistic for the equality of means is reported for equal and unequal variances. Before deciding which test is appropriate, you should look at the test for equality of variances; this test does not indicate a significant difference in the two variances ($F' = 1.23, p = 0.6981$), so the pooled $t$ statistic should be used. Based
on the pooled statistic, the two grazing methods are not significantly different \((t = 0.70, p = 0.4912)\). Note that this test assumes that the observations in both data sets are normally distributed; this assumption can be checked in PROC UNIVARIATE using the raw data.

**Example 77.2. One-Sample Comparison Using the FREQ Statement**

This example examines children’s reading skills. The data consist of Degree of Reading Power (DRP) test scores from 44 third-grade children and are taken from Moore (1995, p. 337). Their scores are given in the following DATA step.

```plaintext
title 'One-Mean Comparison Using FREQ Statement';
data read;
  input score count @@;
datalines;
  40 2 47 2 52 2 26 1 19 2
  25 2 35 4 39 1 26 1 48 1
  14 2 22 1 42 1 34 2 33 2
  18 1 15 1 29 1 41 2 44 1
  51 1 43 1 27 2 46 2 28 1
  49 1 31 1 28 1 54 1 45 1
;run;
```

The following statements invoke the TTEST procedure to test if the mean test score is equal to 30. The COUNT variable contains the frequency of occurrence of each test score; this is specified in the FREQ statement.

```plaintext
proc ttest data=read h0=30;
  var score;
  freq count;
run;
```

The output, shown in **Output 77.2.1**, contains the results.

**Output 77.2.1. TTEST Results**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Lower CL Mean</th>
<th>Mean</th>
<th>Upper CL Mean</th>
<th>Lower CL Std Dev</th>
<th>Mean</th>
<th>Upper CL Std Dev</th>

</tbody>
</table>

T-Tests

<table>
<thead>
<tr>
<th>Variable</th>
<th>DF</th>
<th>t Value</th>
<th>Pr &gt;</th>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td>score</td>
<td>43</td>
<td>2.87</td>
<td>0.0063</td>
<td></td>
</tr>
</tbody>
</table>
The SAS log states that 30 observations and two variables have been read. However, the sample size given in the TTEST output is N=44. This is due to specifying the count variable in the FREQ statement. The test is significant \((t = 2.87, p = 0.0063)\) at the 5% level, thus you can conclude that the mean test score is different from 30.

### Example 77.3. Paired Comparisons

When it is not feasible to assume that two groups of data are independent, and a natural pairing of the data exists, it is advantageous to use an analysis that takes the correlation into account. Utilizing this correlation results in higher power to detect existing differences between the means. The differences between paired observations are assumed to be normally distributed. Some examples of this natural pairing are

- pre- and post-test scores for a student receiving tutoring
- fuel efficiency readings of two fuel types observed on the same automobile
- sunburn scores for two sunblock lotions, one applied to the individual’s right arm, one to the left arm
- political attitude scores of husbands and wives

In this example, taken from *SUGI Supplemental Library User’s Guide, Version 5 Edition*, a stimulus is being examined to determine its effect on systolic blood pressure. Twelve men participate in the study. Their systolic blood pressure is measured both before and after the stimulus is applied. The following statements input the data:

```sas
title 'Paired Comparison';
data pressure;
  input SBPbefore SBPafter @@;
datalines;
120 128 124 131 130 131 118 127
140 132 128 125 140 141 135 137
126 118 130 132 126 129 127 135
;
run;
```

The variables `SBPbefore` and `SBPafter` denote the systolic blood pressure before and after the stimulus, respectively.

The statements to perform the test follow.

```sas
proc ttest;
  paired SBPbefore*SBPafter;
run;
```

The PAIRED statement is used to test whether the mean change in systolic blood pressure is significantly different from zero. The output is displayed in Output 77.3.1.
Output 77.3.1. TTEST Results

The variables SBPbefore and SBPafter are the paired variables with a sample size of 12. The summary statistics of the difference are displayed (mean, standard deviation, and standard error) along with their confidence limits. The minimum and maximum differences are also displayed. The t test is not significant \((t = -1.09, p = 0.2992)\), indicating that the stimuli did not significantly affect systolic blood pressure.

Note that this test of hypothesis assumes that the differences are normally distributed. This assumption can be investigated using PROC UNIVARIATE with the NORMAL option. If the assumption is not satisfied, PROC NPAR1WAY should be used.

Chapter 78
The VARCLUS Procedure

Overview

The VARCLUS procedure divides a set of numeric variables into disjoint or hierarchical clusters. Associated with each cluster is a linear combination of the variables in the cluster. This linear combination can be either the first principal component (the default) or the centroid component (if you specify the CENTROID option). The first principal component is a weighted average of the variables that explains as much variance as possible. See Chapter 58, “The PRINCOMP Procedure,” for further details. Centroid components are unweighted averages of either the standardized variables (the default) or the raw variables (if you specify the COVARIANCE option). PROC VARCLUS tries to maximize the variance that is explained by the cluster components, summed over all the clusters.

The cluster components are oblique, not orthogonal, even when the cluster components are first principal components. In an ordinary principal component analysis, all components are computed from the same variables, and the first principal component is orthogonal to the second principal component and to each other principal component. In PROC VARCLUS, each cluster component is computed from a different set of variables than all the other cluster components. The first principal component of one cluster may be correlated with the first principal component of another cluster. Hence, PROC VARCLUS is a type of oblique component analysis.

As in principal component analysis, either the correlation or the covariance matrix can be analyzed. If correlations are used, all variables are treated as equally important. If covariances are used, variables with larger variances have more importance in the analysis.

PROC VARCLUS creates an output data set that can be used with the SCORE procedure to compute component scores for each cluster. A second output data set can be used by the TREE procedure to draw a tree diagram of hierarchical clusters.

The VARCLUS procedure can be used as a variable-reduction method. A large set of variables can often be replaced by the set of cluster components with little loss of information. A given number of cluster components does not generally explain as much variance as the same number of principal components on the full set of variables, but the cluster components are usually easier to interpret than the principal components, even if the latter are rotated.

For example, an educational test might contain fifty items. PROC VARCLUS can be used to divide the items into, say, five clusters. Each cluster can then be treated as a subtest, with the subtest scores given by the cluster components. If the cluster components are centroid components of the covariance matrix, each subtest score is simply the sum of the item scores for that cluster.
The VARCLUS algorithm is both divisive and iterative. By default, PROC VARCLUS begins with all variables in a single cluster. It then repeats the following steps:

1. A cluster is chosen for splitting. Depending on the options specified, the selected cluster has either the smallest percentage of variation explained by its cluster component (using the PROPORTION= option) or the largest eigenvalue associated with the second principal component (using the MAXEIGEN= option).

2. The chosen cluster is split into two clusters by finding the first two principal components, performing an orthoblique rotation (raw quartimax rotation on the eigenvectors; Harris and Kaiser, 1964), and assigning each variable to the rotated component with which it has the higher squared correlation.

3. Variables are iteratively reassigned to clusters to try to maximize the variance accounted for by the cluster components. You can require the reassignment algorithms to maintain a hierarchical structure for the clusters.

The procedure stops splitting when either:

- the maximum number of clusters as specified by the MAXCLUSTERS= option is reached, or
- each cluster satisfies the stopping criteria specified by the PROPORTION= (percentage of variation explained) and/or the MAXEIGEN= (second eigenvalue) options.

By default, VARCLUS stops splitting when each cluster has only one eigenvalue greater than one, thus satisfying the most popular criterion for determining the sufficiency of a single underlying dimension.

The iterative reassignment of variables to clusters proceeds in two phases. The first is a nearest component sorting (NCS) phase, similar in principle to the nearest centroid sorting algorithms described by Anderberg (1973). In each iteration, the cluster components are computed, and each variable is assigned to the component with which it has the highest squared correlation. The second phase involves a search algorithm in which each variable is tested to see if assigning it to a different cluster increases the amount of variance explained. If a variable is reassigned during the search phase, the components of the two clusters involved are recomputed before the next variable is tested. The NCS phase is much faster than the search phase but is more likely to be trapped by a local optimum.

If principal components are used, the NCS phase is an alternating least-squares method and converges rapidly. The search phase can be very time consuming for a large number of variables. But if the default initialization method is used, the search phase is rarely able to substantially improve the results of the NCS phase, so the search takes few iterations. If random initialization is used, the NCS phase may be trapped by a local optimum from which the search phase can escape.
If centroid components are used, the NCS phase is not an alternating least-squares method and may not increase the amount of variance explained; therefore, it is limited, by default, to one iteration.

You can have VARCLUS do the clustering hierarchically by restricting the reassignment of variables such that the clusters maintain a tree structure. In this case, when a cluster is split, a variable in one of the two resulting clusters can be reassigned to the other cluster resulting from the split but not to a cluster that is not part of the original cluster (the one that is split).

This example demonstrates how you can use the VARCLUS procedure to create hierarchical, unidimensional clusters of variables.

The following data, from Hand, et al. (1994), represent amounts of protein consumed from nine food groups for each of 25 European countries. The nine food groups are red meat (RedMeat), white meat (WhiteMeat), eggs (Eggs), milk (Milk), fish (Fish), cereal (Cereal), starch (Starch), nuts (Nuts), and fruits and vegetables (FruitVeg).

Suppose you want to simplify interpretation of the data by reducing the number of variables to a smaller set of variable cluster components. You can use the VARCLUS procedure for this type of variable reduction.

The following DATA step creates the SAS data set Protein:

```sas
data Protein;
  input Country $18. RedMeat WhiteMeat Eggs Milk Fish Cereal Starch Nuts FruitVeg;
  datalines;
  Albania 10.1 1.4 0.5 8.9 0.2 42.3 0.6 5.5 1.7
  Austria 8.9 14.0 4.3 19.9 2.1 28.0 3.6 1.3 4.3
  Belgium 13.5 9.3 4.1 17.5 4.5 26.6 5.7 2.1 4.0

  Greece 10.2 3.0 2.8 17.6 5.9 41.7 2.2 7.8 6.5
  Hungary 5.3 12.4 2.9 9.7 0.3 40.1 4.0 5.4 4.2
  Ireland 13.9 10.0 4.7 25.8 2.2 24.0 6.2 1.6 2.9
  Italy 9.0 5.1 2.9 13.7 3.4 36.8 2.1 4.3 6.7
  Netherlands 9.5 13.6 3.6 23.4 2.5 22.4 4.2 1.8 3.7
  Norway 9.4 4.7 2.7 23.3 9.7 23.0 4.6 1.6 2.7
  Poland 6.9 10.2 2.7 19.3 3.0 36.1 5.9 2.0 6.6
  Portugal 6.2 3.7 1.1 4.9 14.2 27.0 5.9 4.7 7.9
  Romania 6.2 6.3 1.5 11.1 1.0 49.6 3.1 5.3 2.8
  Spain 7.1 3.4 3.1 8.6 7.0 29.2 5.7 5.9 7.2
  Sweden 9.9 7.8 3.5 4.7 7.5 19.5 3.7 1.4 2.0
  Switzerland 13.1 10.1 3.1 23.8 2.3 25.6 2.8 2.4 4.9
```
The data set Protein contains the character variable Country and the nine numeric variables representing the food groups. The $18. in the INPUT statement specifies that the variable Country is a character variable with a length of 18.

The following statements create the variable clusters.

```sas
proc varclus data=Protein outtree=tree centroid maxclusters=4;
   var RedMeat--FruitVeg;
run;
```

The DATA= option specifies the SAS data set Protein as input. The OUTTREE= option creates the output SAS data set Tree to contain the tree structure information. When you specify this option, you are implicitly requiring the clusters to be hierarchical rather than disjoint.

The CENTROID option specifies the centroid method of clustering. This means that the calculated cluster components are the unweighted averages of the standardized variables. The MAXCLUSTERS=4 option specifies that no more than four clusters be computed.

The VAR statement lists the numeric variables (RedMeat–FruitVeg) to be used in the analysis.

The results of this analysis are displayed in the following figures.

Although PROC VARCLUS displays output for each step in the clustering process, the following figures display only the final analysis for four clusters. Figure 78.1 displays the final cluster summary.

```

Total variation explained = 6.227874 Proportion = 0.6920

**Figure 78.1.** Final Cluster Summary from the VARCLUS Procedure

For each cluster, Figure 78.1 displays the number of variables in the cluster, the cluster variation, the total explained variation, and the proportion of the total variance.
explained by the variables in the cluster. The variance explained by the variables in a cluster is similar to the variance explained by a factor in common factor analysis, but it includes contributions only from the variables in the cluster rather than from all variables.

The line labeled “Total variation explained” in Figure 78.1 gives the sum of the explained variation over all clusters. The final “Proportion” represents the total explained variation divided by the sum of cluster variation. This value, 0.6920, indicates that about 69% of the total variation in the data can be accounted for by the four cluster components.

Figure 78.2 shows how the variables are clustered. The first cluster represents animal protein (RedMeat, WhiteMeat, Eggs, and Milk), the second cluster contains the variables Cereal and Nuts, the third cluster is composed of the variables Fish and Starch, and the last cluster contains the single variable representing fruits and vegetables (FruitVeg).

Figure 78.2. R-square Values from the VARCLUS Procedure

Figure 78.2 also displays the $R^2$ value of each variable with its own cluster and the $R^2$ value with its nearest cluster. The $R^2$ value for a variable with the nearest cluster should be low if the clusters are well separated. The last column displays the ratio of $(1 - R^2_{own})/(1 - R^2_{nearest})$ for each variable. Small values of this ratio indicate good clustering.

Figure 78.3 displays the cluster structure and the intercluster correlations. The structure table displays the correlation of each variable with each cluster component. The table of intercorrelations contains the correlations between the cluster components.

Figure 78.3. Cluster Correlations and Intercorrelations

PROC VARCLUS next displays the summary table of statistics for the cluster history (Figure 78.4). The first three columns give the number of clusters, the total variation explained by clusters, and the proportion of variation explained by clusters.

As displayed in Figure 78.4, when the number of allowable clusters is two, the total variation explained is 3.9607, and the cumulative proportion of variation explained by two clusters is 0.4401. When the number of clusters increases to three, the proportion of explained variance increases to 0.5880. When four clusters are computed, the explained variation is 0.6920.

Figure 78.4. Final Cluster Summary Table from the VARCLUS Procedure

Figure 78.4 also displays the minimum proportion of variance explained by a cluster, the minimum \( R^2 \) for a variable, and the maximum \( (1 - R^2) \) ratio for a variable. The last quantity is the ratio of the value \( 1 - R^2 \) for a variable’s own cluster to the value \( 1 - R^2 \) for its nearest cluster.
The following statements produce a tree diagram of the cluster structure created by PROC VARCLUS. The AXIS1 statement suppresses the label for the vertical axis, which would otherwise be “Name of Variable or Cluster”.

```sas
axis1 label=none;
proc tree data=tree horizontal vaxis=axis1;
   height _propor_
run;
```

Next, the TREE procedure is invoked using the SAS data set TREE, created by the OUTTREE= option in the preceding PROC VARCLUS statement. The HORIZONTAL option orients the tree diagram horizontally. The VAXIS option associates the vertical axis with the the AXIS1 statement. The HEIGHT statement specifies the use of the variable _PROPOR_ (the proportion of variance explained) as the height variable.

**Figure 78.5** shows how the clusters are created. The ordered variable names are displayed on the vertical axis. The horizontal axis displays the proportion of variance explained at each clustering level.

**Figure 78.5.** Horizontal Tree Diagram from PROC TREE

As you look from left to right in the diagram, objects and clusters are progressively joined until a single, all-encompassing cluster is formed at the right (or root) of the diagram. Clusters exist at each level of the diagram, and every vertical line connects leaves and branches into progressively larger clusters.

For example, when the variables are formed into three clusters, one cluster contains the variables RedMeat, WhiteMeat, Eggs, and Milk; the second cluster contains the
variables Fish and Starch; the third cluster contains the variables Cereal, Nuts, and FruitVeg. The proportion of variance explained at that level is 0.5880 (from Figure 78.4). At the next stage of clustering, the third cluster is split as the variable FruitVeg forms the fourth cluster; the proportion of variance explained is 0.6920.

Syntax

The following statements are available in PROC VARCLUS.

```
PROC VARCLUS < options > ;
   VAR variables ;
   SEED variables ;
   PARTIAL variables ;
   WEIGHT variables ;
   FREQ variables ;
   BY variables ;
```

Usually you need only the VAR statement in addition to the PROC VARCLUS statement. The following sections give detailed syntax information for each of the statements, beginning with the PROC VARCLUS statement. The remaining statements are listed in alphabetical order.

PROC VARCLUS Statement

```
PROC VARCLUS < options > ;
```

The PROC VARCLUS statement starts the VARCLUS procedure. By default, VARCLUS clusters the numeric variables in the most recently created SAS data set, starting with one cluster and splitting clusters until all clusters have at most one eigenvalue greater than one.

VARCLUS chooses a cluster to split based on two options: MAXEIGEN=, and PROPORTION=.

1. If you specify either or both of these two options, then only the specified options affect the choice of the cluster to split.

2. If you specify neither of these options, the criterion for choice of cluster to split depends on the CENTROID option:
   (a) If you specify CENTROID, VARCLUS splits the cluster with the smallest percentage of variation explained by its cluster component, as if you had specified the PROPORTION= option.
   (b) If you do not specify CENTROID, VARCLUS splits the cluster with the largest eigenvalue associated with the second principal component, as if you had specified the MAXEIGEN= option.

The final number of clusters is controlled by three options: MAXCLUSTERS=, MAXEIGEN=, and PROPORTION=.
1. If you specify *any* of these three options, then *only* the options you specify affect the final number of clusters.

2. If you specify *none* of these options, VARCLUS continues to split clusters until the default splitting criterion is satisfied. The default splitting criterion depends on the CENTROID option:

   (a) If you specify CENTROID, the default splitting criterion is PROPORTION=0.75.

   (b) If you do not specify CENTROID, splitting is based on the MAXEIGEN= criterion, with a default depending on the COVARIANCE option:

      i. for analyzing a correlation matrix (no COVARIANCE option), the default value for MAXEIGEN= is one.

      ii. for analyzing a covariance matrix (using the COVARIANCE option), the default value for MAXEIGEN= is the average variance of the variables being clustered.

VARCLUS continues to split clusters until any of the following conditions holds:

- the number of cluster equals the value specified for MAXCLUSTERS=.
- no cluster qualifies for splitting according to the MAXEIGEN= or PROPORTION= criteria.
- a cluster was chosen for splitting, but after iteratively reassigning variables to clusters, one of the cluster has no members.
Table 78.1 summarizes some of the options available in the PROC VARCLUS statement.

</tr>
</tbody>
</table>

The following list gives details on these options. The list is in alphabetical order.

**CENTROID**

uses centroid components rather than principal components. You should specify centroid components if you want the cluster components to be unweighted averages of the standardized variables (the default) or the unstandardized variables (if you specify the COVARIANCE option). It is possible to obtain locally optimal clusterings in which a variable is not assigned to the cluster component with which it has the highest squared correlation. You cannot specify both the CENTROID and MAXEIGEN= options.

**CORR**

displays the correlation matrix.
COVARIANCE

COV

analyzes the covariance matrix instead of the correlation matrix. The COVARIANCE option causes variables with a large variance to have more effect on the cluster components than variables with a small variance.

DATA=SAS-data-set

specifies the input data set to be analyzed. The data set can be an ordinary SAS data set or TYPE=CORR, UCORR, COV, UCOV, FACTOR, or SSCP. If you do not specify the DATA= option, the most recently created SAS data set is used. See Appendix A, “Special SAS Data Sets,” for more information on types of SAS data sets.

HIERARCHY

HI

requires the clusters at different levels to maintain a hierarchical structure. To draw a tree diagram, use the OUTTREE= option and the TREE procedure.

INITIAL=GROUP

INITIAL=INPUT

INITIAL=RANDOM

INITIAL=SEED

specifies the method for initializing the clusters. If the INITIAL= option is omitted and the MINCLUSTERS= option is greater than 1, the initial cluster components are obtained by extracting the required number of principal components and performing an orthoblique rotation (raw quartimax rotation on the eigenvectors; Harris and Kaiser, 1964). The following list describes the values for the INITIAL= option:

GROUP obtains the cluster membership of each variable from an observation in the DATA= data set where the _TYPE_ variable has a value of “GROUP”. In this observation, the variables to be clustered must each have an integer value ranging from one to the number of clusters. You can use this option only if the DATA= data set is a TYPE=CORR, UCORR, COV, UCOV, or FACTOR data set. You can use a data set created either by a previous run of PROC VARCLUS or in a DATA step.

INPUT obtains scoring coefficients for the cluster components from observations in the DATA= data set where the _TYPE_ variable has a value of “SCORE”. You can use this option only if the DATA= data set is a TYPE=CORR, UCORR, COV, UCOV, or FACTOR data set. You can use scoring coefficients from the FACTOR procedure or a previous run of PROC VARCLUS, or you can enter other coefficients in a DATA step.

RANDOM assigns variables randomly to clusters.

SEED initializes each cluster component to be one of the variables named in the SEED statement. Each variable listed in the SEED statement becomes the sole member of a cluster, and the other variables are initially unassigned. If you do not specify the SEED statement, the
first MINCLUSTERS= variables in the VAR statement are used as seeds.

**MAXCLUSTERS=n**

specifies the largest number of clusters desired. The default value is the number of variables. VARCLUS stops splitting clusters after the number of clusters reaches the value of the MAXCLUSTERS= option, regardless of what other splitting options are specified.

**MAXEIGEN=n**

specifies that when choosing a cluster to split, VARCLUS should choose the cluster with the largest second eigenvalue, provided that its second eigenvalue is greater than the MAXEIGEN= value. The MAXEIGEN= option cannot be used with the CENTROID or MULTIPLEGROUP options.

If you do not specify MAXEIGEN=, then:

- If you specify PROPORTION=, CENTROID, or MULTIPLEGROUP, cluster splitting does not depend on the second eigenvalue.
- Otherwise, if you specify MAXCLUSTERS=, the default value for MAXEIGEN= is zero.
- Otherwise, the default value for MAXEIGEN= is either 1.0 if the correlation matrix is analyzed, or the average variance if the COVARIANCE option is specified.

If you specify both MAXEIGEN= and MAXCLUSTERS=, the number of clusters will never exceed the value of the MAXCLUSTERS= option.

If you specify both MAXEIGEN= and PROPORTION=, VARCLUS first looks for a cluster to split based on the MAXEIGEN= criterion. If no cluster meets that criterion, VARCLUS then looks for a cluster to split based on the PROPORTION= criterion.

**MAXITER=n**

specifies the maximum number of iterations during the NCS phase. The default value is 1 if you specify the CENTROID option; the default is 10 otherwise.

**MAXSEARCH=n**

specifies the maximum number of iterations during the search phase. The default is 1000 divide by the number of variables.

**MINCLUSTERS=n**

specifies the smallest number of clusters desired. The default value is 2 for INITIAL=RANDOM or INITIAL=SEED; otherwise, VARCLUS begins with one cluster and tries to split it in accordance with the PROPORTION= or MAXEIGEN= options.
**MULTIPLEGROUP**

**MG**

performs a multiple group component analysis (Harman 1976). You specify which variables belong to which clusters. No clusters are split, and no variables are reassigned to a different cluster. The input data set must be TYPE=CORR, UCORR, COV, UCOV, FACTOR or SSCP and must contain an observation with _TYPE_="GROUP" defining the variable groups. Specifying the MULTIPLEGROUP option is equivalent to specifying all of the following options: INITIAL=GROUP, MINC=1, MAXITER=0, MAXSEARCH=0, PROPORTION=0, and MAXEIGEN=large number.

**NOINT**

requests that no intercept be used; covariances or correlations are not corrected for the mean. If you specify the NOINT option, the OUTSTAT= data set is TYPE=UCORR.

**NOPRINT**

suppresses displayed output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

**OUTSTAT=SAS-data-set**

creates an output data set to contain statistics including means, standard deviations, correlations, cluster scoring coefficients, and the cluster structure. If you want to create a permanent SAS data set, you must specify a two-level name. The OUTSTAT= data set is TYPE=UCORR if the NOINT option is specified. For more information on permanent SAS data sets, refer to “SAS Files” and “DATA Step Concepts” in SAS Language Reference: Concepts. For information on types of SAS data sets, see Appendix A, “Special SAS Data Sets.”

**OUTTREE=SAS-data-set**

creates an output data set to contain information on the tree structure that can be used by the TREE procedure to display a tree diagram. The OUTTREE= option implies the HIERARCHY option. See Example 78.1 for use of the OUTTREE= option. If you want to create a permanent SAS data set, you must specify a two-level name. For more information on permanent SAS data sets, refer to “SAS Files” and “DATA Step Concepts” in SAS Language Reference: Concepts.

**PROPORTION=n**

**PERCENT=n**

specifies that when choosing a cluster to split, VARCLUS should choose the cluster with the smallest proportion of variation explained, provided that its proportion of variation explained is less than the PROPORTION= value. Values greater than 1.0 are considered to be percentages, so PROPORTION=0.75 and PERCENT=75 are equivalent.

However, if you specify both MAXEIGEN= and PROPORTION=, VARCLUS first looks for a cluster to split based on the MAXEIGEN= criterion. If no cluster meets that criterion, VARCLUS then looks for a cluster to split based on the PROPORTION= criterion.
If you do not specify PROPORTION= then:

- If you specify MAXEIGEN=, cluster splitting does not depend on the proportion of variation explained.
- Otherwise, if you specify CENTROID and MAXCLUSTERS=, the default value for PROPORTION= is one.
- Otherwise, if you specify CENTROID, without MAXCLUSTERS=, the default value is PROPORTION=0.75 or PERCENT=75.
- Otherwise, cluster splitting does not depend on the proportion of variation explained.

If you specify both PROPORTION= and MAXCLUSTERS=, the number of clusters will never exceed the value of the MAXCLUSTERS= option.

RANDOM=n
specifies a positive integer as a starting value for use with REPLACE=RANDOM. If you do not specify the RANDOM= option, the time of day is used to initialize the pseudo-random number sequence.

SHORT
suppresses display of the cluster structure, scoring coefficient, and intercluster correlation matrices.

SIMPLE
S
displays means and standard deviations.

SUMMARY
suppresses all default displayed output except the final summary table.

TRACE
lists the cluster to which each variable is assigned during the iterations.

VARDEF=DF
VARDEF=N
VARDEF=WDF
VARDEF=WEIGHT | WGT
specifies the divisor to be used in the calculation of variances and covariances. The default value is VARDEF=DF. The values and associated divisors are displayed in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Divisor</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>DF</td>
<td>degrees of freedom</td>
<td>$n - i$</td>
</tr>
<tr>
<td>N</td>
<td>number of observations</td>
<td>$n$</td>
</tr>
<tr>
<td>WDF</td>
<td>sum of weights minus one</td>
<td>$(\sum w_j - 1)$</td>
</tr>
<tr>
<td>WEIGHT</td>
<td>sum of weights</td>
<td>$\sum w_j$</td>
</tr>
</tbody>
</table>

In the preceding table, $i = 0$ if the NOINT option is specified, and $i = 1$ otherwise.
BY Statement

BY variables;

You can specify a BY statement with PROC VARCLUS to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARCLUS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

FREQ Statement

FREQ variable;

If a variable in your data set represents the frequency of occurrence for the other values in the observation, include the variable’s name in a FREQ statement. The procedure then treats the data set as if each observation appears n times, where n is the value of the FREQ variable for the observation. If the value of the FREQ variable is less than 1, the observation is not used in the analysis. Only the integer portion of the value is used. The total number of observations is considered equal to the sum of the FREQ variable.

PARTIAL Statement

PARTIAL variable;

If you want to base the clustering on partial correlations, list the variables to be partialled out in the PARTIAL statement.
**SEED Statement**

```plaintext
SEED variables;
```

The SEED statement specifies variables to be used as seeds to initialize the clusters. It is not necessary to use INITIAL=SEED if the SEED statement is present, but if any other INITIAL= option is specified, the SEED statement is ignored.

**VAR Statement**

```plaintext
VAR variables;
```

The VAR statement specifies the variables to be clustered. If you do not specify the VAR statement and do not specify TYPE=SSCP, all numeric variables not listed in other statements (except the SEED statement) are processed. The default VAR variable list does not include the variable INTERCEPT if the DATA= data set is TYPE=SSCP. If the variable INTERCEPT is explicitly specified in the VAR statement with a TYPE=SSCP data set, the NOINT option is enabled.

**WEIGHT Statement**

```plaintext
WEIGHT variables;
```

If you want to specify relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances. The WEIGHT variable can take nonintegral values. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero.

**Details**

**Missing Values**

Observations containing missing values are omitted from the analysis.
Using PROC VARCLUS

Default options for PROC VARCLUS often provide satisfactory results. If you want to change the final number of clusters, use the MAXCLUSTERS=, MAXEIGEN=, or PROPORTION= options. The MAXEIGEN= and PROPORTION= options usually produce similar results but occasionally cause different clusters to be selected for splitting. The MAXEIGEN= option tends to choose clusters with a large number of variables, while the PROPORTION= option is more likely to select a cluster with a small number of variables.

Execution time

PROC VARCLUS usually requires more computer time than principal factor analysis, but it can be faster than some of the iterative factoring methods. If you have more than 30 variables, you may want to reduce execution time by one or more of the following methods:

- Specify the MINCLUSTERS= and MAXCLUSTERS= options if you know how many clusters you want.
- Specify the HIERARCHY option.
- Specify the SEED statement if you have some prior knowledge of what clusters to expect.

If computer time is not a limiting factor, you may want to try one of the following methods to obtain a better solution:

- If the clustering algorithm has not converged, specify larger values for MAXITER= and MAXSEARCH=.
- Try several factoring and rotation methods with PROC FACTOR to use as input to PROC VARCLUS.
- Run PROC VARCLUS several times, specifying INITIAL=RANDOM.
Output Data Sets

OUTSTAT= Data Set

The OUTSTAT= data set is TYPE=CORR, and it can be used as input to the SCORE procedure or a subsequent run of PROC VARCLUS. The variables it contains are

- BY variables
- _NCL_, a numeric variable giving the number of clusters
- _TYPE_, a character variable indicating the type of statistic the observation contains
- _NAME_, a character variable containing a variable name or a cluster name, which is of the form CLUSn where n is the number of the cluster
- the variables that are clustered

The values of the _TYPE_ variable are listed in the following table.

<table>
<thead>
<tr>
<th><em>TYPE</em></th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEAN</td>
<td>means</td>
</tr>
<tr>
<td>STD</td>
<td>standard deviations</td>
</tr>
<tr>
<td>USTD</td>
<td>uncorrected standard deviations, produced when the NOINT option is specified</td>
</tr>
<tr>
<td>N</td>
<td>number of observations</td>
</tr>
<tr>
<td>CORR</td>
<td>correlations</td>
</tr>
<tr>

</tr>
<tr>
<td>MEMBERS</td>
<td>number of members in each cluster</td>
</tr>
<tr>
<td>VAREXP</td>
<td>variance explained by each cluster</td>
</tr>
<tr>
<td>PROPOR</td>
<td>proportion of variance explained by each cluster</td>
</tr>
<tr>
<td>GROUP</td>
<td>number of the cluster to which each variable belongs</td>
</tr>
<tr>
<td>RSQUARED</td>
<td>squared multiple correlation of each variable with its cluster component</td>
</tr>
<tr>
<td>SCORE</td>
<td>standardized scoring coefficients</td>
</tr>
<tr>
<td>USCORE</td>
<td>scoring coefficients to be applied without subtracting the mean from the raw variables, produced when the NOINT option is specified</td>
</tr>
<tr>
<td>STRUCTUR</td>
<td>cluster structure</td>
</tr>
<tr>
<td>CCORR</td>
<td>correlations between cluster components</td>
</tr>
</tbody>
</table>

The observations with _TYPE_="MEAN", "STD", "N", and "CORR" have missing values for the _NCL_ variable. All other values of the _TYPE_ variable are repeated for each cluster solution, with different solutions distinguished by the value of the _NCL_ variable. If you want to specify the OUTSTAT= data set with the SCORE procedure, you can use a DATA step to select observations with the _NCL_ variable missing or equal to the desired number of clusters.
data Coef2;
  set Coef;
  if _ncl_ = . or _ncl_ = 3;
  drop _ncl_;
run;
proc score data=NewScore score=Coef2; run;

PROC SCORE standardizes the new data by subtracting the original variable means
that are stored in the _TYPE_=’MEAN’ observations, and dividing by the original variable standard deviations from the _TYPE_=’STD’ observations. Then
PROC SCORE multiplies the standardized variables by the coefficients from the
_TYPE_=’SCORE’ observations to get the cluster scores.

OUTTREE= Data Set

The OUTTREE= data set contains one observation for each variable clustered plus
one observation for each cluster of two or more variables, that is, one observation for
each node of the cluster tree. The total number of output observations is between \( n \)
and \( 2n - 1 \), where \( n \) is the number of variables clustered.

The variables in the OUTTREE= data set are

- **BY** variables, if any
- _NAME_, a character variable giving the name of the node. If the node is a
  cluster, the name is CLUS\( n \) where \( n \) is the number of the cluster. If the node
  is a single variable, the variable name is used.
- _PARENT_, a character variable giving the value of _NAME_ of the parent
  of the node. If the node is the root of the tree, _PARENT_ is blank.
- _LABEL_, a character variable giving the label of the node. If the node is a
  cluster, the label is CLUS\( n \) where \( n \) is the number of the cluster. If the node is a
  single variable, the variable label is used.
- _NCL_, the number of clusters.
- _VAREXP_, the total variance explained by the clusters at the current level of
  the tree.
- _PROPOR_, the total proportion of variance explained by the clusters at the
  current level of the tree.
- _MINPRO_, the minimum proportion of variance explained by a cluster com-
  ponent.
- _MAXEIG_, the maximum second eigenvalue of a cluster.
Computational Resources

Let

\[ n = \text{number of observations} \]
\[ v = \text{number of variables} \]
\[ c = \text{number of clusters} \]

It is assumed that, at each stage of clustering, the clusters all contain the same number of variables.

Time

The time required for PROC VARCLUS to analyze a given data set varies greatly depending on the number of clusters requested, the number of iterations in both the alternating least-squares and search phases, and whether centroid or principal components are used.

The time required to compute the correlation matrix is roughly proportional to \( nv^2 \).

Default cluster initialization requires time roughly proportional to \( v^3 \). Any other method of initialization requires time roughly proportional to \( cv^2 \).

In the alternating least-squares phase, each iteration requires time roughly proportional to \( cv^2 \) if centroid components are used or

\[
\left( c + 5 \frac{v}{c^2} \right) v^2
\]

if principal components are used.

In the search phase, each iteration requires time roughly proportional to \( v^3/c \) if centroid components are used or \( v^4/c^2 \) if principal components are used. The HIERARCHY option speeds up each iteration after the first split by as much as \( c/2 \).

Memory

The amount of memory, in bytes, needed by PROC VARCLUS is approximately

\[ v^2 + 2vc + 20v + 15c \]

Interpreting VARCLUS Procedure Output

Because PROC VARCLUS is a type of oblique component analysis, its output is similar to the output from the FACTOR procedure for oblique rotations. The scoring coefficients have the same meaning in both PROC VARCLUS and PROC FACTOR; they are coefficients applied to the standardized variables to compute component scores. The cluster structure is analogous to the factor structure containing the correlations between each variable and each cluster component. A cluster pattern is not displayed because it would be the same as the cluster structure, except that zeros would appear
in the same places in which zeros appear in the scoring coefficients. The intercluster
correlations are analogous to interfactor correlations; they are the correlations among
cluster components.

PROC VARCLUS also displays a cluster summary and a cluster listing. The cluster
summary gives the number of variables in each cluster and the variation explained
by the cluster component. The latter is similar to the variation explained by a factor
but includes contributions from only the variables in that cluster rather than from all
variables, as in PROC FACTOR. The proportion of variance explained is obtained by
dividing the variance explained by the total variance of variables in the cluster. If the
cluster contains two or more variables and the CENTROID option is not used, the
second largest eigenvalue of the cluster is also displayed.

The cluster listing gives the variables in each cluster. Two squared correlations are
calculated for each cluster. The column labeled “Own Cluster” gives the squared
correlation of the variable with its own cluster component. This value should be
higher than the squared correlation with any other cluster unless an iteration limit
has been exceeded or the CENTROID option has been used. The larger the squared
correlation is, the better. The column labeled “Next Closest” contains the next highest
squared correlation of the variable with a cluster component. This value is low if the
clusters are well separated. The column headed “1–R**2 Ratio” gives the ratio of one
minus the “Own Cluster” $R^2$ to one minus the “Next Closest” $R^2$. A small “1–R**2
Ratio” indicates a good clustering.

**Displayed Output**

The following items are displayed for each cluster solution unless the NOPRINT or
SUMMARY option is specified. The CLUSTER SUMMARY table includes

- the Cluster number
- Members, the number of members in the cluster
- Cluster Variation of the variables in the cluster
- Variation Explained by the cluster component. This statistic is based only on
  the variables in the cluster rather than on all variables.
- Proportion Explained, the result of dividing the variation explained by the clus-
  ter variation
- Second Eigenvalue, the second largest eigenvalue of the cluster. This is dis-
  played if the cluster contains more than one variable and the CENTROID op-
  tion is not specified

PROC VARCLUS also displays

- Total variation explained, the sum across clusters of the variation explained by
  each cluster
- Proportion, the total explained variation divided by the total variation of all the
  variables
The cluster listing includes

- **Variable**, the variables in each cluster
- **R-squared with Own Cluster**, the squared correlation of the variable with its own cluster component; and **R-squared with Next Closest**, the next highest squared correlation of the variable with a cluster component. Own Cluster values should be higher than the $R^2$ with any other cluster unless an iteration limit is exceeded or you specify the CENTROID option. Next Closest should be a low value if the clusters are well separated.
- **1–R**$^2$ **Ratio**, the ratio of one minus the value in the Own Cluster column to one minus the value in the Next Closest column. The occurrence of low ratios indicates well-separated clusters.

If the SHORT option is not specified, PROC VARCLUS also displays

- **Standardized Scoring Coefficients**, standardized regression coefficients for predicting cluster components from variables
- **Cluster Structure**, the correlations between each variable and each cluster component
- **Inter-Cluster Correlations**, the correlations between the cluster components

If the analysis includes partitions for two or more numbers of clusters, a final summary table is displayed. Each row of the table corresponds to one partition. The columns include

- **Number of Clusters**
- **Total Variation Explained by Clusters**
- **Proportion of Variation Explained by Clusters**
- **Minimum Proportion (of variation) Explained by a Cluster**
- **Maximum Second Eigenvalue in a Cluster**
- **Minimum R-squared for a Variable**
- **Maximum 1–R**$^2$ **Ratio for a Variable**

**ODS Table Names**

PROC VARCLUS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”
Table 78.3. ODS Tables Produced in PROC VARCLUS

Example

Example 78.1. Correlations among Physical Variables

The following data are correlations among eight physical variables as given by Harman (1976). The first PROC VARCLUS run clusters on the basis of principal components, the second run clusters on the basis of centroid components. The third analysis is hierarchical, and the TREE procedure is used to display a tree diagram. The results of the analyses follow.

data phys8(type=corr);
  title 'Eight Physical Measurements on 305 School Girls';
  title2 'Harman: Modern Factor Analysis, 3rd Ed, p22';
  label height='Height' arm_span='Arm Span'
    forearm='Length of Forearm'
    low_leg='Length of Lower Leg'
    weight='Weight' bit_diam='Bitrochanteric Diameter'
    girth='Chest Girth' width='Chest Width';
  input _name_ $ 1-8
    (height arm_span forearm low_leg weight bit_diam
    girth width)(7.);
  _type_='corr';
datalines;
height  1.0  .846  .805  .859  .473  .398  .301  .382
arm_span  .846  1.0  .881  .826  .376  .326  .277  .415
forearm   .805  .881  1.0  .801  .380  .319  .237  .345
low_leg   .859  .826  .801  1.0  .436  .329  .327  .365
weight    .473  .376  .380  .436  1.0  .762  .730  .629
bit_diam  .398  .326  .319  .329  .762  1.0  .583  .577
girth     .301  .277  .237  .327  .730  .583  1.0  .539
width     .382  .415  .345  .365  .629  .577  .539  1.0
;
proc varclus data=phys8;
run;
The PROC VARCLUS statement invokes the procedure. By default, PROC VARCLUS clusters on the basis of principal components.

</tbody>
</table>

No cluster meets the criterion for splitting.

As displayed in **Output 78.1.1**, the cluster component (by default, the first principal component) explains 58.41% of the total variation in the 8 variables.

The cluster is split because the second eigenvalue is greater than 1 (the default value of the MAXEIGEN option).

The two resulting cluster components explain 80.33% of the variation in the original variables. The cluster summary table shows that the variables **height**, **arm_span**, **forearm**, and **low_leg** have been assigned to the first cluster; and that the variables **weight**, **bit_diam**, **girth**, and **width** have been assigned to the second cluster.
The standardized scoring coefficients in Output 78.1.2 show that each cluster component has similar scores for each of its associated variables. This suggests that the principal cluster component solution should be similar to the centroid cluster component solution, which follows in the next PROC VARCLUS run.

The cluster structure table displays high correlations between the variables and their own cluster component. The correlations between the variables and the opposite cluster component are all moderate.

The intercluster correlation table shows that the cluster components are moderately correlated with $\rho = 0.44513$.

In the following statements, the CENTROID option in the PROC VARCLUS statement specifies that cluster centroids be used as the basis for clustering.

```sas
proc varclus data=phys8 centroid;
run;
```
The first cluster component, which, in the centroid method, is an unweighted sum of the standardized variables, explains 57.89% of the variation in the data. This value is near the maximum possible variance explained, 58.41%, which is attained by the first principal component (Output 78.1.1).

The centroid clustering algorithm splits the variables into the same two clusters created in the principal component method. Recall that this outcome was suggested by the similar standardized scoring coefficients in the principal cluster component solution.

The default behavior in the centroid method is to split any cluster with less than 75% of the total cluster variance explained by the centroid component. In the next step, the second cluster, with a component that explains only 72.75% of the total variation of the cluster, is split.

In the R-squared table for two clusters, the width variable has a weaker relation to its cluster than any other variable; in the three cluster solution this variable is in a cluster of its own.
Example 78.1. Correlations among Physical Variables

Output 78.1.5. Standardized Scoring Coefficients

Oblique Centroid Component Cluster Analysis

</tbody>
</table>

The centroid method stops at the three cluster solution. As displayed in Output 78.1.6 and Output 78.1.7, the three centroid components account for 86.15% of the variability in the eight variables, and all cluster components account for at least 79.44% of the total variation in the corresponding cluster. Additionally, the smallest squared correlation between the variables and their own cluster component is 0.7482.
Output 78.1.7. Cluster Quality Table

<table>
<thead>
<tr>
<th>Number of Clusters</th>
<th>Total Variation of Explained by Clusters</th>
<th>Proportion of Variation Explained by Clusters</th>
<th>Minimum Proportion Explained by a Cluster</th>
<th>Minimum R-squared for a Variable</th>
<th>Maximum 1-R**2 Ratio for a Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4.631000</td>
<td>0.5789</td>
<td>0.5789</td>
<td>0.4306</td>
<td></td>
</tr>
<tr>

<td>0.8615</td>
<td>0.7944</td>
<td>0.7482</td>
<td>0.3548</td>
</tr>
</tbody>
</table>

Note that, if the proportion option were set to a value between 0.5789 (the proportion of variance explained in the 1-cluster solution) and 0.7275 (the minimum proportion of variance explained in the 2-cluster solution), PROC VARCLUS would stop at a two cluster solution, and the centroid solution would find the same clusters as the principal components solution.

In the following statements, the MAXC= option computes all clustering solutions, from one to eight clusters. The SUMMARY option suppresses all output except the final cluster quality table, and the OUTTREE= option saves the results of the analysis to an output data set and forces the clusters to be hierarchical. The TREE procedure is invoked to produce a graphical display of the clusters.

```plaintext
proc varclus data=phys8 maxc=8 summary outtree=tree;
run;

goptions ftext=swiss;
axis2 label=(justify=left);
axis1 order=(0.5 to 1.0 by 0.1);
proc tree horizontal vaxis=axis2 haxis=axis1 lines=(width=2);
height _propor_;
id _label_;
run;
```

Output 78.1.8. Hierarchical Clusters and the SUMMARY Option

</tr>
</tbody>
</table>

The principal component method first separates the variables into the same two clusters that were created in the first PROC VARCLUS run. Note that, in creating the third cluster, the principal component method identifies the variable `width`. This is...
the same variable that is put into its own cluster in the preceding centroid method example.

**Output 78.1.9.** TREE Diagram from PROC TREE

<table>
<thead>
<tr>
<th>Name of Variable or Cluster</th>
</tr>
</thead>
<tbody>

<tr>
<td>low_leg</td>
</tr>
<tr>
<td>arm_span</td>
</tr>
<tr>
<td>forearm</td>
</tr>
</tbody>
</table>

The tree diagram in **Output 78.1.9** displays the cluster hierarchy. It is clear from the diagram that there are two, or possibly three, clusters present. However, the MAXC=8 option forces PROC VARCLUS to split the clusters until each variable is in its own cluster.

Chapter 79
The VARCOMP Procedure

Overview

The VARCOMP procedure handles general linear models that have random effects. Random effects are classification effects with levels that are assumed to be randomly selected from an infinite population of possible levels. PROC VARCOMP estimates the contribution of each of the random effects to the variance of the dependent variable.

A single MODEL statement specifies the dependent variables and the effects: main effects, interactions, and nested effects. The effects must be composed of class variables; no continuous variables are allowed on the right side of the equal sign.

You can specify certain effects as fixed (nonrandom) by putting them first in the MODEL statement and indicating the number of fixed effects with the FIXED= option. An intercept is always fitted and assumed fixed. Except for the effects specified as fixed, all other effects are assumed to be random, and their contribution to the model can be thought of as an observation from a distribution that is normally and independently distributed.

The dependent variables are grouped based on the similarity of their missing values. Each group of dependent variables is then analyzed separately. The columns of the design matrix $X$ are formed in the same order in which the effects are specified in the MODEL statement. No reparameterization is done. Thus, the columns of $X$ contain only 0s and 1s.

You can specify four methods of estimation in the PROC VARCOMP statement using the METHOD= option. They are TYPE1 (based on computation of Type I sum of squares for each effect), MIVQUE0, Maximum Likelihood (METHOD=ML), and Restricted Maximum Likelihood (METHOD=REML).
Chapter 79. The VARCOMP Procedure

Getting Started

Analyzing the Cure Rate of Rubber

This example, using data from Hicks (1973), concerns an experiment to determine the sources of variability in cure rates of rubber. The goal of the experiment was to find out if the different laboratories contributed more to the variance of cure rates than did the different batches of raw materials. This information would be useful in trying to control the cure rate of the final product because it would provide insights into the sources of the variability in cure rates. The rubber used was cured at three temperatures, which were taken to be fixed. Three laboratories were chosen at random, and three different batches of raw material were tested at each combination of temperature and laboratory. The following statements read the data into the SAS data set `Cure`.

```sas

;
```

The variables `Lab`, `Temp`, and `Batch` contain levels of laboratory, temperature, and batch, respectively. The `Cure` variable contains the response values.
The following SAS statements perform a restricted maximum-likelihood variance component analysis.

\[
\text{proc varcomp method=reml;}
\text{  class Temp Lab Batch;}
\text{  model Cure=Temp|Lab Batch(Lab Temp) / fixed=1;}
\text{run;}
\]

The FIXED=1 option indicates that the first factor, \text{Temp}, is fixed. The effect specification \text{Temp|Lab} is equivalent to putting the three terms \text{Temp}, \text{Lab}, and \text{Temp*Lab} in the model. \text{Batch(Lab Temp)} is equivalent to putting \text{Batch(Temp*Lab)} in the MODEL statement. The results of this analysis are displayed in Figure 79.1 through Figure 79.4.

\begin{verbatim}
Figure 79.1. Class Level Information
Figure 79.1 provides information about the variables used in the analysis and the number of observations and specifies the dependent variable.

Figure 79.2. Iteration History
\end{verbatim}
The “REML Iterations” table, shown in Figure 79.2, displays the iteration history, which includes the value of the objective function associated with REML and the values of the variance components at each iteration.

<table>

</tbody>
</table>

Figure 79.4. Covariance Matrix for REML Estimates

The “Asymptotic Covariance Matrix of Estimates” table in Figure 79.4 displays the asymptotic covariance matrix of the REML estimates.

The results of the analysis show that the variance attributable to Batch(Temp*Lab) (with a variance component of 2.0739) is considerably larger than the variance attributable to Lab (0.3176). Therefore, attempts to reduce the variability of cure rates should concentrate on improving the homogeneity of the batches of raw material used rather than standardizing the practices or equipment within the laboratories. Also, note that since the Batch(Temp*Lab) variance is considerably larger than the experimental error (Var(Error)=0.6026), the Batch(Temp*Lab) variability plays an important part in the overall variability of the cure rates.
Syntax

The following statements are available in PROC VARCOMP.

```
PROC VARCOMP < options > ;
   CLASS variables ;
   MODEL dependent = < effects > < / options > ;
   BY variables ;
```

Only one MODEL statement is allowed. The BY, CLASS, and MODEL statements are described after the PROC VARCOMP statement.

PROC VARCOMP Statement

```
PROC VARCOMP < options > ;
```

This statement invokes the VARCOMP procedure. You can specify the following options in the PROC VARCOMP statement.

- **DATA=SAS-data-set**
  specifies the input SAS data set to use. If this option is omitted, the most recently created SAS data set is used.

- **EPSILON=number**
  specifies the convergence value of the objective function for METHOD=ML or METHOD=REML. By default, EPSILON=1E−8.

- **MAXITER=number**
  specifies the maximum number of iterations for METHOD=ML or METHOD=REML. By default, MAXITER=50.

- **METHOD=TYPE1 | MIVQUE0 | ML | REML**
  specifies which of the four methods (TYPE1, MIVQUE0, ML, or REML) you want to use. By default, METHOD= MIVQUE0. For more information see the “Computational Methods” section on page 4838.

BY Statement

```
BY variables ;
```

You can specify a BY statement with PROC VARCOMP to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

If your input data set is not sorted in ascending order, use one of the following alternatives.
Sort the data using the SORT procedure with a similar BY statement.

Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, see the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, see the discussion in the *SAS Procedures Guide*.

### CLASS Statement

**CLASS** variables ;

The CLASS statement specifies the classification variables to be used in the analysis. All effects in the MODEL statement must be composed of effects that appear in the CLASS statement. Class variables can be either numeric or character; if they are character, only the first 16 characters are used.

Numeric class variables are not restricted to integers since a variable’s format determines the levels. For more information, see the discussion of the FORMAT statement in *SAS Language Reference: Dictionary*.

### MODEL Statement

**MODEL** dependent = < effects > < / option > ;

The MODEL statement gives the dependent variables and independent effects. If you specify more than one dependent variable, a separate analysis is performed for each one. The independent effects are limited to main effects, interactions, and nested effects; no continuous effects are allowed. All independent effects must be composed of effects that appear in the CLASS statement. Effects are specified in the VARCOMP procedure in the same way as described for the ANOVA procedure. Only one MODEL statement is allowed.

Only one option is available in the MODEL statement.

**FIXED=**n

tells the VARCOMP procedure that the first n effects in the MODEL statement are fixed effects. The remaining effects are assumed to be random. By default, PROC VARCOMP assumes that all effects are random in the model. Keep in mind that if you use bar notation and, for example, specify **Y=A|B / FIXED=2**, then **A*B** is considered a random effect.
Details

Missing Values

If an observation has a missing value for any variable used in the independent effects, then the analyses of all dependent variables omit this observation. An observation is deleted from the analysis of a given dependent variable if the observation’s value for that dependent variable is missing. Note that a missing value in one dependent variable does not eliminate an observation from the analysis of the other dependent variables.

During processing, PROC VARCOMP groups the dependent variables on their missing values across observations so that sums of squares and cross products can be computed in the most efficient manner.

Fixed and Random Effects

Central to the idea of variance components models is the idea of fixed and random effects. Each effect in a variance components model must be classified as either a fixed or a random effect. Fixed effects arise when the levels of an effect constitute the entire population about which you are interested. For example, if a plant scientist is comparing the yields of three varieties of soybeans, then Variety would be a fixed effect, providing that the scientist was concerned about making inferences on only these three varieties of soybeans. Similarly, if an industrial experiment focused on the effectiveness of two brands of a machine, Machine would be a fixed effect only if the experimenter’s interest did not go beyond the two machine brands.

On the other hand, an effect is classified as a random effect when you want to make inferences on an entire population, and the levels in your experiment represent only a sample from that population. Psychologists comparing test results between different groups of subjects would consider Subject as a random effect. Depending on the psychologists’ particular interest, the Group effect might be either fixed or random. For example, if the groups are based on the sex of the subject, then Sex would be a fixed effect. But if the psychologists are interested in the variability in test scores due to different teachers, then they might choose a random sample of teachers as being representative of the total population of teachers, and Teacher would be a random effect. Note that, in the soybean example presented earlier, if the scientists are interested in making inferences on the entire population of soybean varieties and randomly choose three varieties for testing, then Variety would be a random effect.

If all the effects in a model (except for the intercept) are considered random effects, then the model is called a random effects model; likewise, a model with only fixed effects is called a fixed-effects model. The more common case, where some factors are fixed and others are random, is called a mixed model. In PROC VARCOMP, by default, effects are assumed to be random. You specify which effects are fixed by using the FIXED= option in the MODEL statement. In general, if an interaction or nested effect contains any effect that is random, then the interaction or nested effect should be considered as a random effect as well.
In the linear model, each level of a fixed effect contributes a fixed amount to the expected value of the dependent variable. What makes a random effect different is that each level of a random effect contributes an amount that is viewed as a sample from a population of normally distributed variables, each with mean 0, and an unknown variance, much like the usual random error term that is a part of all linear models. The estimate of the variance associated with the random effect is known as the variance component because it is measuring the part of the overall variance contributed by that effect. Thus, PROC VARCOMP estimates the variance of the random variables that are associated with the random effects in your model, and the variance components tell you how much each of the random factors contributes to the overall variability in the dependent variable.

### Negative Variance Component Estimates

The variance components estimated by PROC VARCOMP should theoretically be nonnegative because they are assumed to represent the variance of a random variable. Nevertheless, when you are using METHOD=MIVQUE0 (the default) or METHOD=TYPE1, some estimates of variance components may become negative. (Due to the nature of the algorithms used for METHOD=ML and METHOD=REML, negative estimates are constrained to zero.) These negative estimates may arise for a variety of reasons:

- The variability in your data may be large enough to produce a negative estimate, even though the true value of the variance component is positive.
- Your data may contain outliers. Refer to Hocking (1983) for a graphical technique for detecting outliers in variance components models using the SAS System.
- A different model for interpreting your data may be appropriate. Under some statistical models for variance components analysis, negative estimates are an indication that observations in your data are negatively correlated. Refer to Hocking (1984) for further information about these models.

Assuming that you are satisfied that the model PROC VARCOMP is using is appropriate for your data, it is common practice to treat negative variance components as if they are zero.

### Computational Methods

Four methods of estimation can be specified in the PROC VARCOMP statement using the METHOD= option. They are described in the following sections.

#### The Type I Method

This method (METHOD=TYPE1) computes the Type I sum of squares for each effect, equates each mean square involving only random effects to its expected value, and solves the resulting system of equations (Gaylor, Lucas, and Anderson 1970). The $X'X \mid X'Y$ matrix is computed and adjusted in segments whenever memory is not sufficient to hold the entire matrix.
The **MIVQUE0 Method**

Based on the technique suggested by Hartley, Rao, and LaMotte (1978), the MIVQUE0 method (METHOD=MIVQUE0) produces unbiased estimates that are invariant with respect to the fixed effects of the model and that are locally best quadratic unbiased estimates given that the true ratio of each component to the residual error component is zero. The technique is similar to TYPE1 except that the random effects are adjusted only for the fixed effects. This affords a considerable timing advantage over the TYPE1 method; thus, MIVQUE0 is the default method used in PROC VARCOMP. The $X'X|X'Y$ matrix is computed and adjusted in segments whenever memory is not sufficient to hold the entire matrix. Each element $(i, j)$ of the form

$$SSQ(X'_i M X_j)$$

is computed, where

$$M = I - X_0(X'_0 X_0)^{-1} X'_0$$

and where $X_0$ is part of the design matrix for the fixed effects, $X_i$ is part of the design matrix for one of the random effects, and SSQ is an operator that takes the sum of squares of the elements. For more information refer to Rao (1971, 1972) and Goodnight (1978).

The **Maximum Likelihood Method**

The objective function for METHOD=ML is $\ln(|V|) + r'V^{-1}r$, where

$$V = \sigma^2_0 I + \sum_{i=1}^{n_r} \sigma^2_i X_i X'_i$$

and where $\sigma^2_0$ is the residual variance, $n_r$ is the number of random effects in the model, $\sigma^2_i$ represents the variance components, $X_i$ is part of the design matrix for one of the random effects, and

$$r = y - X_0(X'_0 V^{-1} X_0)^{-1} X'_0 V^{-1} y$$

is the vector of residuals.
The Restricted Maximum Likelihood Method

The Restricted Maximum Likelihood Method (METHOD=REML) is similar to the maximum likelihood method, but it first separates the likelihood into two parts: one that contains the fixed effects and one that does not (Patterson and Thompson 1971). The procedure uses a Newton-Raphson algorithm, iterating until convergence is reached for the log-likelihood objective function of the portion of the likelihood that does not contain the fixed effects. Using notation from earlier methods, the objective function for METHOD=REML is \( \ln(|V|) + r'V^{-1}r + \ln(|X_0'V^{-1}X_0|) \). Refer to Searle, Casella, and McCulloch (1992) for additional details.

Displayed Output

PROC VARCOMP displays the following items:

- Class Level Information for verifying the levels in your data
- Number of observations read from the data set and number of observations used in the analysis
- for METHOD=TYPE1, an analysis-of-variance table with Source, DF, Type I Sum of Squares, Type I Mean Square, and Expected Mean Square, and a table of Type I variance component estimates
- for METHOD=MIVQUE0, the SSQ Matrix containing sums of squares of partitions of the \( X'X \) crossproducts matrix adjusted for the fixed effects
- for METHOD=ML and METHOD=REML, the iteration history, including the objective function, as well as variance component estimates
- for METHOD=ML and METHOD=REML, the estimated Asymptotic Covariance Matrix of the variance components
- a table of variance component estimates

ODS Table Names

PROC VARCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”
Table 79.1. ODS Tables Produced in PROC VARCOMP

<table>
<thead>
<tr>

<td>METHOD=MIVQUE0</td>
</tr>
</tbody>
</table>

In situations where multiple dependent variables are analyzed that differ in their missing value pattern, separate names for ANOVA, AsyCov, Estimates, IterHistory, and SSCP tables are no longer required. The results are combined into a single output data set. For METHOD=TYPE1, ML, or REML, variable Dependent in the output data set identifies the dependent variable. For METHOD=MIVQUE0, a variable is added to the output data set for each dependent variable.

Relationship to PROC MIXED

The MIXED procedure effectively performs the same analyses as PROC VARCOMP and many others, including Type I, Type II, and Type III tests of fixed effects, confidence limits, customized contrasts, and least-squares means. Furthermore, continuous variables are permitted as both fixed and random effects in PROC MIXED, and numerous other covariance structures besides variance components are available.

To translate PROC VARCOMP code into PROC MIXED code, move all random effects to the RANDOM statement in PROC MIXED. For example, the syntax for the example in the “Getting Started” section on page 4832 is as follows:

```plaintext
proc mixed;
   class Temp Lab Batch;
   model Cure = Temp;
   random Lab Temp*Lab Batch(Lab Temp);
run;
```

REML is the default estimation method in PROC MIXED, and you can specify other methods using the METHOD= option.
Example

Example 79.1. Using the Four Estimation Methods

In this example, a and b are classification variables and y is the dependent variable. a is declared fixed, and b and a*b are random. Note that this design is unbalanced because the cell sizes are not all the same. PROC VARCOMP is invoked four times, once for each of the estimation methods. The data are from Hemmerle and Hartley (1973). The following statements produce Output 79.1.1.

```datalog

The Type I analysis of variance consists of sequentially partitioning the total sum of squares. The mean square is the sum of squares divided by the degrees of freedom, and the expected mean square is the expected value of the mean square under the mixed model. The “Q” notation in the expected mean squares refers to a quadratic form in parameters of the parenthesized effect.

<td>0</td>
</tr>
<tr>
<td>Var(Error)</td>
<td>77.53049</td>
</tr>
</tbody>
</table>

The ML estimate of Var(a*b) is zero for this example, and the other two estimates are smaller than their Type I and MIVQUE0 counterparts.

Variance Components Estimation Procedure
Asymptotic Covariance Matrix of Estimates

\[
\begin{array}{ccc}
\text{Var}(b) & \text{Var}(a*b) & \text{Var}(\text{Error}) \\
\text{Var}(b) & 537826.1 & 0 & -107.33905 \\
\text{Var}(a*b) & 0 & 0 & 0 \\
\text{Var}(\text{Error}) & -107.33905 & 0 & 858.71104 \\
\end{array}
\]

One benefit of using likelihood-based methods is that an approximate covariance matrix is available from the matrix of second derivatives evaluated at the ML solution. This covariance matrix is valid asymptotically and can be unreliable in small samples.

Here the variance component estimates for B and the Error are negatively correlated and the elements for Var(a*b) are set to zero because the estimate equals zero. Also, the very large variance for Var(b) indicates a lot of uncertainty about the estimate for Var(b), and one contributing explanation is that B has only two levels in this data set.
The “Class Level Information” is the same as before.

Chapter 80
The VARIOGRAM Procedure

Overview

The VARIOGRAM procedure computes sample or empirical measures of spatial continuity for two-dimensional spatial data. These continuity measures are the regular semivariogram, a robust version of the semivariogram, and the covariance. The continuity measures are written to an output data set, allowing plotting or parameter estimation for theoretical semivariogram or covariance models. Both isotropic and anisotropic measures are available.

The VARIOGRAM procedure produces two additional output data sets that are useful in the analysis of pairwise distances in the original data. The OUTPAIR= data set contains one observation for each pair of points. The coordinates, distance, angle, and values of the analysis variables are written to this data set. The OUTDISTANCE= data set contains histogram information on the count of pairs within distance intervals, which is useful for determining unit lag distances.

Introduction to Spatial Prediction

Spatial prediction, in general, is any prediction method that incorporates spatial dependence. A simple and popular spatial prediction method is ordinary kriging.

Ordinary kriging requires a model of the spatial continuity, or dependence. This is typically in the form of a covariance or semivariogram.

Spatial prediction, then, involves two steps. First, you model the covariance or semivariogram of the spatial process. This involves choosing both a mathematical form and the values of the associated parameters. Second, you use this dependence model in solving the kriging system at a specified set of spatial points, resulting in predicted values and associated standard errors.

SAS/STAT software has two procedures corresponding to these steps for spatial prediction of two-dimensional data. The VARIOGRAM procedure is used in the first step. By computing a sample estimate of the variogram or covariance, you can choose a theoretical model based on graphical or other means.
Getting Started

In activities such as reservoir estimation in mining, petroleum exploration, and environmental modeling of air and water pollution, it often happens that data on one or more quantities are available at given spatial locations, and the goal is to predict the measured quantities at unsampled locations. Often, these unsampled locations are on a regular grid, and the predictions are used to produce surface plots or contour maps.

A popular method of spatial prediction is ordinary kriging, which produces both predicted values and associated standard errors. Ordinary kriging requires the complete specification (the form and parameter values) of the spatial dependence of the spatial process in terms of a covariance or semivariogram model.

Typically the semivariogram model is not known in advance and must be estimated, either visually or by some estimation method.

PROC VARIOGRAM computes the sample semivariogram, from which you can find a suitable theoretical semivariogram by visual methods.

The following example goes through a typical problem to show how you can compute a sample variogram and determine an appropriate theoretical model.

Preliminary Spatial Data Analysis

The simulated data consist of coal seam thickness measurements (in feet) taken over an approximately square area. The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

First, the data are input.

It is instructive to see the locations of the measured points in the area where you want to perform spatial prediction. It is desirable to have these locations scattered evenly around the prediction area. If this is not the case, the prediction error might be unacceptably large where measurements are sparse. The following GPLOT procedure is useful in determining potential problems:

```sas
proc gplot data=thick;
  title 'Scatter Plot of Measurement Locations';
  plot north*east / frame cframe=ligr haxis=axis1 vaxis=axis2;
  symbol1 v=dot color=blue;
  axis1 minor=none;
  axis2 minor=none label=(angle=90 rotate=0);
  label east = 'East'
              north = 'North'
;
run;
```
As Figure 80.1 indicates, while the locations are not ideally spread around the prediction area, there are not any large areas lacking measurements. You now can look at a surface plot of the measured variable, the thickness of coal seam, using the G3D procedure. This is a crucial step. Any obvious surface trend has to be removed before you compute and estimate the model of spatial dependence (the semivariogram model).

```plaintext
proc g3d data=thick;
   title 'Surface Plot of Coal Seam Thickness';
   scatter east*north=thick / xticknum=5 yticknum=5
      grid zmin=20 zmax=65;
   label east = 'East'
      north = 'North'
      thick = 'Thickness'
   ;
run;
```
Figure 80.2. Surface Plot of Coal Seam Thickness

Figure 80.2 shows the small-scale variation typical of spatial data, but there does not appear to be any surface trend. Hence, you can work with the original thickness data rather than residuals from a trend surface fit.
Preliminary Variogram Analysis

Recall that the goal of this example is spatial prediction. In particular, you would like to produce a contour map or surface plot on a regular grid of predicted values based on ordinary kriging. Ordinary kriging requires the complete specification of the spatial covariance or semivariogram.

You can use PROC VARIOGRAM, along with a DATA step and PROC GPLOT, to estimate visually a reasonable semivariogram model (both the form and associated parameters) for the thickness data.

Before proceeding with this estimation, consider the formula for the empirical or experimental semivariogram $\gamma_z(h)$. Denote the coal seam thickness process by $\{Z(r), r \in D \subset \mathbb{R}^2\}$. You have measurements $\{Z(r_i), i = 1, \ldots, 75\}$. The standard formula for $\gamma_z(h)$ (isotropic case) is

$$2\gamma_z(h) = \frac{1}{|N(h)|} \sum_{N(h)} (Z(r_i) - Z(r_j))^2$$

where $N(h)$ is given by

$$N(h) = \{i, j : |r_i - r_j| = h\}$$

and $|N(h)|$ is the number of such pairs $(i, j)$.

For actual data, it is unlikely that any pair $(i, j)$ would exactly satisfy $|r_i - r_j| = h$, so typically a range of pairwise distances, $|r_i - r_j| \in [h - \delta h, h + \delta h)$, is used to group pairs $(r_i, r_j)$ for a single term in the expression for $\gamma_z(h)$. Using this range, $N(h)$ is modified by

$$N(h, \delta h) = \{i, j : |r_i - r_j| \in [h - \delta h, h + \delta h)\}$$

PROC VARIOGRAM performs this grouping with two required options for variogram computation: the LAGDISTANCE= and MAXLAGS= options.

The meaning of the required LAGDISTANCE= option is as follows. Classify all pairs of points into intervals according to their pairwise distance. The width of the distance interval is the LAGDISTANCE= value. The meaning of the required MAXLAGS= option is simply the number of intervals.

The problem is that a surface plot of the original data, or the scatter plot of the measurement locations, is not very helpful in determining the distribution of these pairwise distances; it is not clear what values to give to the LAGDISTANCE= and MAXLAGS= options.

You use PROC VARIOGRAM with the OUTFDISTANCE= option to produce a modified histogram of the pairwise distances in order to find reasonable values for the LAGDISTANCE= and MAXLAGS= options. In the following analysis, you use the
NOVARIOGRAM option in the COMPUTE statement and the OUTDISTANCE= option in the PROC VARIOGRAM statement. You need the NOVARIOGRAM option to keep an error message from being issued due to the absence of the LAGDISTANCE= and MAXLAGS= options.

The DATA step after the PROC VARIOGRAM statement computes the midpoint of each distance interval. This midpoint is then used in the GCHART procedure. Since the number of distance intervals is not specified by using the NHCLASSES= option in the COMPUTE statement, the default of 10 is used.

```plaintext
proc variogram data=thick outdistance=outd;
    compute novariogram;
    coordinates xc=east yc=north;
    var thick;
run;

title 'OUTDISTANCE= Data Set Showing Distance Intervals';
proc print data=outd;
run;

data outd; set outd;
    mdpt=round((lb+ub)/2,.1);
    label mdpt = 'Midpoint of Interval';
run;

axis1 minor=none;
axis2 minor=none label=(angle=90 rotate=0);
title 'Distribution of Pairwise Distances';
proc gchart data=outd;
    vbar mdpt / type=sum sumvar=count discrete frame
        cframe=ligr gaxis=axis1 raxis=axis2 nolegend;
run;
```

Figure 80.3. OUTDISTANCE= Data Set Showing Distance Intervals
For plotting and estimations purposes, it is desirable to have as many points as possible for the plot of $\gamma_z(h)$ against $h$. This corresponds to having as many distance intervals as possible, that is, having a small value for the LAGDISTANCE= option.

However, a rule of thumb used in computing sample semivariograms is to use at least 30 point pairs in computing a single value of the empirical or experimental semivariogram.

If the LAGDISTANCE= value is set too small, there may be too few points in one or more of the intervals. On the other hand, if the LAGDISTANCE= value is set to a large value, the number of point pairs in the distance intervals may be much greater than that needed for estimation precision, thereby “wasting” point pairs at the expense of variogram points.

Hence, there is a tradeoff between the number of distance intervals and the number of point pairs within each interval.

As discussed in the section “OUTDIST=SAS-data-set” on page 4878 the first few distance intervals, corresponding to lag 0 and lag 1, are typically the limiting intervals. This is particularly true for lag 0 since it is half the width of the remaining intervals. For the default of NHCLASSES=10, the lag 0 class contains 45 points, which is reasonably close to 30, but the lag 1 class contains 263 points.
If you rerun PROC VARIOGRAM with NHCLASSES=20, these numbers become 8 and 83 for lags 0 and 1, respectively. Because of the asymmetrical nature of lag 0, you are willing to violate the rule of thumb for the 0th lag. You will, however, have sufficient numbers in lag 1 and above.

```
proc variogram data=thick outdistance=outd;
   compute nhc=20 novariogram;
   coordinates xc=east yc=north;
   var thick;
run;

title 'OUTDISTANCE= Data Set Showing Distance Intervals';
proc print data=outd;
run;

data outd; set outd;
   mdpt=round((lb+ub)/2,.1);
   label mdpt = 'Midpoint of Interval';
run;

axis1 minor=none;
axis2 minor=none label=(angle=90 rotate=0);
title 'Distribution of Pairwise Distances';
proc gchart data=outd;
   vbar mdpt / type=sum sumvar=count discrete frame
      cframe=ligr gaxis=axis1 raxis=axis2 nolegend;
run;
```

Figure 80.5. OUTDISTANCE= Data Set Showing Distance Intervals
The length of the lag 1 class \((3.484, 10.453)\) is 6.969. You round off and use \(\text{LAGDISTANCE}=7.0\) in the COMPUTE statement.

The use of the \(\text{MAXLAGS} = \) option is more difficult. From Figure 80.5, note that up to a pairwise distance of 101, you have a sufficient number of pairs. With your choice of \(\text{LAGDISTANCE}=7.0\), this yields a maximum number of lags \(\frac{101}{7} \approx 14\).

The problem with using the maximum lag value is that it includes pairs of points so far apart that they are likely to be independent. Using pairs of points that are independent adds nothing to the empirical semivariogram plot; they are essentially added noise.

If there is an estimate of correlation length, perhaps from a prior geologic study of a similar site, you can specify the \(\text{MAXLAGS} = \) value so that the maximum pairwise distance does not exceed two or three correlation lengths. If there is no estimate of correlation length, you can use the following rule of thumb: use \(\frac{1}{2}\) to \(\frac{3}{4}\) of the “diameter” of the region containing the data. A \(\text{MAXLAGS} = \) value of 10 is within this range.

You now rerun PROC VARIOGRAM with these values.
Sample Variogram Computation and Plots

Using the values of LAGDISTANCE=7.0 and MAXLAGS=10 computed previously, rerun PROC VARIOGRAM without the NOVARIogram option. Also, request a robust version of the semivariogram; then, plot both results against the pairwise distance of each class.

```sas
proc variogram data=thick outv=outv;
   compute lagd=7 maxlag=10 robust;
   coordinates xc=east yc=north;
   var thick;
run;

title 'OUTVAR= Data Set Showing Sample Variogram Results';
proc print data=outv label;
   var lag count distance variog rvario;
run;

data outv2; set outv;
   vari=variog; type = 'regular'; output;
   vari=rvario; type = 'robust'; output;
run;

Figure 80.7. OUTVAR= Data Set Showing Sample Variogram Results

Standard and Robust Semivariogram for Coal Seam Thickness Data

Figure 80.8. Standard and Robust Semivariogram for Coal Seam Thickness Data
Figure 80.8 shows a slow, then a rapid rise from the origin, suggesting a Gaussian type form:

\[ \gamma_z(h) = c_0 \left[ 1 - \exp \left( -\frac{h^2}{a_0^2} \right) \right] \]

See the section “Theoretical and Computational Details of the Semivariogram” on page 4872 for graphs of the standard semivariogram forms.

By experimentation, you find that a scale of \( c_0 = 7.5 \) and a range of \( a_0 = 30 \) fits reasonably well for both the robust and standard semivariogram.

The following statements plot the sample and theoretical variograms:

```plaintext
data outv3; set outv;
c0=7.5; a0=30;
  vari = c0*(1-exp(-distance*distance/(a0*a0)));
  type = 'Gaussian'; output;
  vari = variog; type = 'regular'; output;
  vari = rvario; type = 'robust'; output;
run;
```

title 'Theoretical and Sample Semivariogram for Coal Seam Thickness Data';
proc gplot data=outv3;
  plot vari*distance=type / frame cframe=ligr vaxis=axis2
     haxis=axis1;
  symbol1 i=join l=1 c=blue /* v=star */;
  symbol2 i=join l=1 c=yellow /* v=square */;
  symbol3 i=join l=1 c=cyan /* v=diamond */;
  axis1 minor=none
     label=(c=black 'Lag Distance') /* offset=(3,3) */;
  axis2 order=(0 to 9 by 1) minor=none
     label=(angle=90 rotate=0 c=black 'Variogram') /* offset=(3,3) */;
run;
```
Figure 80.9 shows that the choice of a semivariogram model is adequate. You can use this Gaussian form and these particular parameters in PROC KRIGE2D to produce a contour plot of the kriging estimates and the associated standard errors.

**Syntax**

The following statements are available in PROC VARIOGRAM.

```
PROC VARIOGRAM options;
   COMPUTE computation-options;
   COORDINATES coordinate-variables;
   DIRECTIONS directions-list;
   VAR analysis-variables-list;
```

The COMPUTE and COORDINATES statements are required.

The following table outlines the options available in PROC VARIOGRAM classified by function.
### PROC VARIOGRAM Statement

PROC VARIOGRAM options ;

You can specify the following options in the PROC VARIOGRAM statement.

**DATA=SAS-data-set**

specifies a SAS data set containing the \( x \) and \( y \) coordinate variables and the VAR statement variables.

**OUTDISTANCE=SAS-data-set**

**OUTDISTA\$=SAS-data-set**

**OUTD=SAS-data-set**

specifies a SAS data set in which to store summary distance information. This data set contains a count of all pairs of data points within a given distance interval. The number of distance intervals is controlled by the NHCLASSES= option in the COMPUTE statement. The OUTDISTANCE= data set is useful for plotting mod-

</table>
ified histograms of the count data for determining appropriate lag distances. See the section “OUTDIST=SAS-data-set” on page 4878 for details.

**OUTPAIR=SAS-data-set**

**OUTP=SAS-data-set**

specifies a SAS data set in which to store distance and angle information for each pair of points in the DATA= data set. This option should be used with caution when the DATA= data set is large. If \( n \) denotes the number of observations in the DATA= data set, the OUTPAIR= data set contains \( \frac{n(n-1)}{2} \) observations unless you restrict it with the OUTPDISTANCE= option in the COMPUTE statement. The OUTPDISTANCE= option in the COMPUTE statement excludes pairs of points when the distance between the pairs exceeds the OUTPDISTANCE= value. See the section “OUTPAIR=SAS-data-set” on page 4881 for details.

**OUTVAR=SAS-data-set**

**OUTVR=SAS-data-set**

specifies a SAS data set in which to store the continuity measures. See the section “OUTVAR=SAS-data-set” on page 4877 for details.

**COMPUTE Statement**

```plaintext
COMPUTE computation-options ;
```

The COMPUTE statement provides a number of options that control the computation of the semivariogram, the robust semivariogram, and the covariance.

**ANGLETOLERANCE=angle tolerance**

**ANGLETOL=angle tolerance**

**ATOL=angle tolerance**

specifies the tolerance, in degrees, around the angles determined by the NDIReCTIONS= specification. The default is \( \frac{180^\circ}{\Sigma n_d} \), where \( n_d \) is the NDIReCTIONS= specification.

See the section “Theoretical and Computational Details of the Semivariogram” on page 4872 for more detailed information.

**BANDWIDTH=bandwidth distance**

**BANDW=bandwidth distance**

specifies the bandwidth, or perpendicular distance cutoff for determining the angle class for a given pair of points. The distance classes define a series of cylindrically shaped areas, while the angle classes radially cut these cylindrically shaped areas. For a given angle class \((\theta_1 - \delta \theta_1, \theta_1 + \delta \theta_1)\), as you proceed out radially, the area encompassed by this angle class becomes larger. The BANDWIDTH= option restricts this area by excluding all points with a perpendicular distance from the line \( \theta = \theta_1 \) that is greater than the BANDWIDTH= value.

If you do not specify the BANDWIDTH= option, no restriction occurs. See Figure 80.15 on page 4876 for more detailed information.
**DEPSILON=** distance value

**DEPS=** distance value

specifies the distance value for declaring that two distinct points are zero distance apart. Such pairs, if they occur, cause numeric problems. If you specify DEPSILON=\( \varepsilon \), then pairs of points \( P_1 \) and \( P_2 \) for which the distance between them \( |P_1P_2| < \varepsilon \) are excluded from the continuity measure calculations. The default value of the DEPSILON= option is 100 times machine epsilon; this product is approximately 1E-10 on most computers.

**LAGDISTANCE=** distance unit

**LAGDIST=** distance unit

**LAGD=** distance unit

specifies the basic distance unit defining the lags. For example, a specification of LAGDISTANCE=\( x \) results in lag distance classes that are multiples of \( x \). For a given pair of points \( P_1 \) and \( P_2 \), the distance between them, denoted \( |P_1P_2| \), is calculated. If \( |P_1P_2| = x \), then this pair is in the first lag class. If \( |P_1P_2| = 2x \), then this pair is in the second lag class, and so on.

For irregularly spaced data, the pairwise distances are unlikely to fall exactly on multiples of the LAGDISTANCE= value. A distance tolerance of \( \delta x \) is used to accommodate a spread of distances around multiples of \( x \) (the LAGTOLERANCE= option specifies the distance tolerance). For example, if \( |P_1P_2| \) is within \( x \pm \delta x \), you would place this pair in the first lag class; if \( |P_1P_2| \) is within \( 2x \pm \delta x \), you would place this pair in the second lag class, and so on.

You can determine the candidate values for the LAGDISTANCE= option by plotting or displaying the OUTDISTANCE= data set.

A LAGDISTANCE= value is required unless you specify the NOVARIOGRAM option.

See the section “Theoretical and Computational Details of the Semivariogram” on page 4872 for more details.

**LAGTOLERANCE=** tolerance number

**LAGTOL=** tolerance number

**LAGT=** tolerance number

specifies the tolerance around the LAGDISTANCE= value for grouping distance pairs into lag classes. See the preceding description of the LAGDISTANCE= option for information on the use of the LAGTOLERANCE= option, and see the section “Theoretical and Computational Details of the Semivariogram” on page 4872 for more details.

If you do not specify the LAGTOLERANCE= option, a default value of \( (1/2) \) times the LAGDISTANCE= value is used.

**MAXLAGS=** number of lags

**MAXLAG=** number of lags

**MAXL=** number of lags

specifies the maximum number of lag classes used in constructing the continuity measures. This option excludes any pair of points \( P_1 \) and \( P_2 \) for which the distance
between them, $|P_1P_2|$, exceeds the MAXLAGS= value times the LAGDISTANCE= value.

You can determine candidate values for the MAXLAGS= option by plotting or displaying the OUTDISTANCE= data set.

A MAXLAGS= value is required unless you specify the NOVARIOGRAM option.

NDIRECTIONS=number of directions
NDIR=number of directions
ND=number of directions

specifies the number of angle classes to use in computing the continuity measures. This option is useful when there is potential anisotropy in the spatial continuity measures. Anisotropy occurs when the spatial continuity or dependence between a pair of points depends on the orientation or angle between the pair. Isotropy is the absence of this effect: the spatial continuity or dependence between a pair of points depends only on the distance between the points, not the angle.

The angle classes formed from the NDIRECTIONS= option start from N–S and proceed clockwise. For example, NDIRECTIONS=3 produces three angle classes. In terms of compass points, these classes are centered at 0° (or its reciprocal 180°), 60° (or its reciprocal 240°), and 120° (or its reciprocal 300°). For irregularly spaced data, the angles between pairs are unlikely to fall exactly in these directions, so an angle tolerance of $\delta\theta$ is used (the ANGLETOLERANCE= option specifies the angle tolerance). If NDIRECTIONS=$n_d$, the base angle is $\theta = \frac{180°}{n_d}$, and the angle classes are

$$(k\theta - \delta\theta, k\theta + \delta\theta) \quad k = 0, \ldots, n_d - 1$$

If you do not specify the NDIRECTIONS= option, no angles are formed, and the spatial continuity measures are assumed to be isotropic.

The NDIRECTIONS= option is useful for exploring possible anisotropy. The DIRECTIONS statement, described in the “DIRECTIONS Statement” section on page 4870, provides greater control over the angle classes. See the section “Theoretical and Computational Details of the Semivariogram” on page 4872 for more detailed information.

NHCLASSES=number of histogram classes
NHCLASS=number of histogram classes
NHC=number of histogram classes

specifies the number of distance or histogram classes to write to the OUTDISTANCE= data set. The actual number of classes is one more than the NHCLASSES= value since a special lag 0 class is also computed. See the OUTDISTANCE= option on page 4865 and the section “OUTDIST=SAS-data-set” on page 4878 for details.

The default value of the NHCLASSES= option is 10. This option is ignored if you do not specify an OUTDISTANCE= data set.
NOVARIOGAR

prevents the computation of the continuity measures. This option is useful for preliminary analysis when you require only the OUTDISTANCE= or OUTPAIR= data sets.

OUTPDISTANCE=\textit{distance limit}
OUTPDIST=\textit{distance limit}
OUTPD=\textit{distance limit}

specifies the cutoff distance for writing observations to the OUTPAIR= data set. If you specify OUTPDISTANCE=\textit{d}_{\text{max}}, the distance \mid P_1P_2 \mid between each pair of points \textit{P}_1 and \textit{P}_2 is checked against \textit{d}_{\text{max}}. If \mid P_1P_2 \mid > \textit{d}_{\text{max}}, the observation for this pair is not written to the OUTPAIR= data set. If you do not specify the OUTPDISTANCE= option, all distinct pairs are written. This option is ignored if you do not specify an OUTPAIR= data set.

ROBUST

requests that a robust version of the semivariogram be calculated in addition to the regular semivariogram and covariance.

\textbf{COORDINATES Statement}

\texttt{COORDINATES coordinate-variables ;}

The following two options give the names of the variables in the DATA= data set containing the values of the \textit{x} and \textit{y} coordinates of the data.

Only one COORDINATES statement is allowed, and it is applied to all the analysis variables. In other words, it is assumed that all the VAR variables have the same \textit{x} and \textit{y} coordinates.

\texttt{XCOORD= (variable-name)}
\texttt{XC= (variable-name)}
gives the name of the variable containing the \textit{x} coordinate of the data in the DATA= data set.

\texttt{YCOORD= (variable-name)}
\texttt{YC= (variable-name)}
gives the name of the variable containing the \textit{y} coordinate of the data in the DATA= data set.
DIRECTIONS Statement

DIRECTIONS directions-list ;

You use the DIRECTIONS statement to define angle classes. You can specify angle classes as a list of angles, separated by commas, with optional angle tolerances and bandwidths within parentheses following the angle. You must specify at least one angle.

If you do not specify the optional angle tolerance, the default value of 45° is used. If you do not specify the optional bandwidth, no bandwidth is checked. If you specify a bandwidth, you must also specify an angle tolerance.

For example, suppose you want to compute three separate semivariograms at angles \( \theta_1 = 0^\circ, \theta_2 = 60^\circ, \) and \( \theta_3 = 120^\circ, \) with corresponding angle tolerance \( \delta \theta_1 = 22.5^\circ, \delta \theta_2 = 12.5^\circ, \) and \( \delta \theta_3 = 22.5^\circ, \) with bandwidths 50 and 40 distance units on the first two angle classes and no bandwidth check on the last angle class.

The appropriate DIRECTIONS statement is

\[ \text{directions } 0.0(22.5,50), 60.0(12.5,40), 120(22.5); \]

VAR Statement

VAR analysis-variables-list ;

Use the VAR statement to specify the analysis variables. You can specify only numeric variables. If you do not specify a VAR statement, all numeric variables in the DATA= data set that are not in the COORDINATES statement are used.

Details

Theoretical Semivariogram Models

The VARIOGRAM procedure computes the sample, or experimental semivariogram. Prediction of the spatial process at unsampled locations by techniques such as ordinary kriging requires a theoretical semivariogram or covariance.

It is necessary, then, to decide on a theoretical variogram based on the sample variogram. While there are methods of fitting semivariogram models, such as least squares, maximum likelihood, and robust methods (Cressie 1993, section 2.6), these techniques are not appropriate for data sets resulting in a small number of variogram points. Instead, a visual fit of the variogram points to a few standard models is often satisfactory. Even when there are sufficient variogram points, a visual check against a fitted theoretical model is appropriate (Hohn 1988, p. 25ff).
In some cases, a plot of the experimental semivariogram suggests that a single theoretical model is inadequate. Nested models, anisotropic models, and the nugget effect increase the scope of theoretical models available. All of these concepts are discussed in this section. The specification of the final theoretical model is provided by the syntax of PROC KRIGE2D.

Note the general flow of investigation. After a suitable choice is made of the LAGDIST= and MAXLAGS= options and, possibly, the NDIR= option (or a DIRECTIONS statement), the experimental semivariogram is computed. Potential theoretical models, possibly incorporating nesting, anisotropy, and the nugget effect, are computed by a DATA step, then they are plotted against the experimental semivariogram and evaluated. A suitable theoretical model is thus found visually, and the specification of the model is used in PROC KRIGE2D. This flow is illustrated in Figure 80.10; also see the “Getting Started” section on page 4852 for an illustration in a simple case.

![Figure 80.10. Flowchart for Variogram Selection](image-url)
Theoretical and Computational Details of the Semivariogram

The basic starting point in computing the semivariogram is the enumeration of pairs of points for the spatial data. Figure 80.11 shows a spatial domain in which a set of measurements are made at the indicated locations. Two points \( P_1 \) and \( P_2 \), with coordinates \((x_1, y_1), (x_2, y_2)\), are selected for illustration. A vector, or directed line segment, is drawn between these points. This pair is then categorized first by orientation of this directed line segment and then by its length. That is, the pair \( P_1 P_2 \) is placed into an angle and distance class.

**Figure 80.11.** Selection of Points \( P_1 \) and \( P_2 \) in Spatial Domain

**Angle Classification**

Suppose you specify \( \text{NDIR}=3 \) in the COMPUTE statement in PROC VARIOGRAM. This results in three angle classes defined by midpoint angles between \( 0^\circ \) and \( 180^\circ \): 

\[
0^\circ \pm \delta \theta, \ 60^\circ \pm \delta \theta, \ \text{and} \ 120^\circ \pm \delta \theta,
\]

where \( \delta \theta \) is the angle tolerance. If you do not specify an angle tolerance using the \( \text{ATOL=} \) option in the COMPUTE statement, the following default value is used.

\[
\delta \theta = \frac{180^\circ}{2 \times \text{NDIR}}
\]
For three classes, $\delta \theta = 30^\circ$. When the example directed line segment $P_1P_2$ is superimposed on the coordinate system showing the angle classes, its angle, measured clockwise from north, is approximately $45^\circ$. In particular, it falls within $[60^\circ - \delta \theta, 60^\circ + \delta \theta) = [30^\circ, 90^\circ)$, the second angle class. See Figure 80.12.

![Figure 80.12. Selected Pair P₁P₂ Falls within the Second Angle Class](image)

Note that if the designated points $P_1$ and $P_2$ are labeled in the opposite order, the orientation is in a reciprocal direction, that is, approximately $225^\circ$ for the point pair instead of approximately $45^\circ$. This does not affect angle class selection; the angle classes $[60^\circ - \delta \theta, 60^\circ + \delta \theta)$ and $[240^\circ - \delta \theta, 240^\circ + \delta \theta)$ are the same.

If you specify an angle tolerance less than the default, for example, $ATOL = 15^\circ$, some point pairs might be excluded. For example, the selected point pair $P_1P_2$ in Figure 80.12, while closest to the $60^\circ$ axis, might lie outside $[60^\circ - \delta \theta, 60^\circ + \delta \theta) = [45^\circ, 75^\circ)$. In this case, the point pair $P_1P_2$ would be excluded from the variogram computation.

On the other hand, you can specify an angle tolerance greater than the default. This can result in a point pair being counted in more than one angle class. This has a smoothing effect on the variogram and is useful when there is a small amount of data available.

An alternative way to specify angle classes and angle tolerances is with the DIRECTIONS statement. The DIRECTIONS statement is useful when angle classes are not equally spaced. When you specify the DIRECTIONS statement, you should also specify the angle tolerance. The default value of the angle tolerance is $45^\circ$. 
when a DIRECTIONS statement is used instead of the NDIRECTIONS= option in the COMPUTE statement. This may not be appropriate for a particular set of angle classes. See the “DIRECTIONS Statement” section on page 4870 for more details on the DIRECTIONS statement.

**Distance Classification**

Next, the distance class for the point pair \( P_1P_2 \) is determined. The directed line segment \( P_1P_2 \) is superimposed on the coordinate system showing the distance or lag classes. These classes are determined by the LAGD= specification in the COMPUTE statement. Denoting the length of the line segment by \(| P_1P_2 | \) and the LAGD value by \( \Delta \), the lag class \( L \) is determined by

\[
L(P_1P_2) = \left\lfloor \frac{|P_1P_2| + 0.5}{\Delta} \right\rfloor
\]

where \( \lfloor x \rfloor \) denotes the largest integer \( \leq x \).

When the directed line segment \( P_1P_2 \) is superimposed on the coordinate system showing the distance classes, it is seen to fall in the first lag class; see Figure 80.13 for an illustration for \( \Delta = 1 \).

---

**Figure 80.13.** Selected Pair \( P_1P_2 \) Falls within the First Lag Class

Because pairwise distances are positive, lag class zero is smaller than lag classes \( 1, \cdots, \text{MAXLAG} - 1 \). For example, if you specify LAGD=1.0 and MAXLAG=10,
and you do not specify a LAGTOL= value in the COMPUTE statement in PROC VARIOGRAM, the ten lag classes generated by the preceding equation are

\[ (0, .5), [.5, 1.5), [1.5, 2.5), \cdots, [8.5, 9.5) \]

This is because the default lag tolerance is one-half the LAGD= value, resulting in no gaps between the distance class intervals. This is shown in Figure 80.14.

![Figure 80.14. Lag Distance Axis Showing Lag Classes](image)

Figure 80.14. Lag Distance Axis Showing Lag Classes

On the other hand, if you do specify a distance tolerance with the DTOL= option in the COMPUTE statement, a further check is performed to see if the point pair falls within this tolerance of the nearest lag. In the preceding example, if you specify LAGD=1.0 and MAXLAG=10 (as before) and also specify LAGTOL=0.25, the intervals become

\[ (0, 0.25), [0.75, 1.25), [1.75, 2.25), \cdots, [8.75, 9.25) \]

Note that this specification results in gaps in the lag classes; a point pair \( P_1 P_2 \) might fall, for example, in the interval

\[ | P_1 P_2 | \in [1.25, 1.75) \]

and hence be excluded from the semivariogram calculation. The maximum LAGTOL= value allowed is half the LAGD= value; no overlap of the distance classes is allowed.

**Bandwidth Restriction**

Because the areal segments generated from the angle and distance classes increase in area as the lag distance increases, it is sometimes desirable to restrict this area (Duetsch and Journel 1992, p. 45). If you specify the BANDW= option in the COMPUTE statement, the lateral, or perpendicular, distance from the axis defining the angle classes is fixed.

For example, suppose two points \( P_3, P_4 \) are picked from the domain in Figure 80.11 and are superimposed on the grid defining distance and angle classes, as shown in Figure 80.15.
Figure 80.15. Selected Pair \(P_3P_4\) Falls Outside Bandwidth Limit

The endpoint of vector \(P_3P_4\) falls within the angle class around \(60^\circ\) and the 5th lag class; however, it falls outside the restricted area defined by the bandwidth. Hence, it is excluded from the semivariogram calculation.

Finally, a pair \(P_iP_j\) that falls in a lag class larger than the value of the MAXLAG= option is excluded from the semivariogram calculation.

From this description, it is clear that the number of pairs within each angle/distance class is strongly affected by the angle and lag tolerances. Since it is desirable to have the maximum number of point pairs within each class, the angle tolerance and the distance tolerance should usually be the default values.

**Semivariogram Computation**

With the classification of a point pair \(P_iP_j\) into an angle/distance class, as shown in the preceding section, the semivariogram computation proceeds as follows.

Denote all pairs \(P_iP_j\) belonging to angle class \([\theta_k - \delta\theta_k, \theta_k + \delta\theta_k]\) and distance class \(L = L(P_iP_j)\) by \(N(\theta_k, L)\). For example, in the preceding illustration, \(P_1P_2\) belongs to \(N(60^\circ, 1)\).

Let \(|N(\theta_k, L)|\) denote the number of such pairs. Let \(V_i, V_j\) be the measured values at points \(P_i, P_j\). The component of the standard (or method of moments) semivariogram
Output Data Sets

The VARIOGRAM procedure produces three data sets: the OUTVAR=SAS-data-set, the OUTPAIR=SAS-data-set, and the OUTDIST=SAS-data-set. These data sets are described in the following sections.

OUTVAR=SAS-data-set

The OUTVAR= data set contains the standard and robust versions of the sample semivariogram, the covariance, and other information at each lag class.

The details of the computation of the variogram, the robust variogram, and the covariance is described in the section “Theoretical and Computational Details of the Semivariogram” on page 4872.

The OUTVAR= data set contains the following variables:

- **ANGLE**, which is the angle class value (clockwise from N–S)
- **ATOL**, which is the angle tolerance for the lag/angle class
- **AVERAGE**, which is the average variable value for the lag/angle class
• BANDW, which is the band width for the lag/angle class
• COUNT, which is the number of pairs in the lag/angle class
• COVAR, which is the covariance value for the lag/angle class
• DISTANCE, which is the average lag distance for the lag/angle class
• LAG, which is lag class value (in LAGDISTANCE= units)
• RVARIO, which is the sample robust variogram value for the lag/angle class
• VARIOG, which is the sample variogram value for the lag/angle class
• VARNAME, which is the name of the current VAR= variable

The bandwidth variable, BANDW, is not included in the data set if no bandwidth specification is given in the COMPUTE statement or in a DIRECTIONS statement.

OUTDIST=SAS-data-set

The OUTDIST= data set contains counts for a modified histogram showing the distribution of pairwise distances. The purpose of this data set is to enable you to make choices for the value of the LAGDISTANCE= option in the COMPUTE statement in subsequent runs of PROC VARIOGRAM.

For plotting and estimation purposes, it is desirable to have as many points as possible for a variogram plot. However, a rule of thumb used in computing sample semivariograms is to use at least 30 points in each interval whenever possible. Hence, there is a lower limit to the value of the LAGDISTANCE= option.

Since the distribution of pairwise distances is seldom known in advance, the information contained in the OUTDIST= data set enables you to choose, in an iterative fashion, a value for the LAGDISTANCE= parameter. The value you choose is a compromise between the number of pairs making up each variogram point and the number of variogram points.

In some cases, the pattern of measured points may result in some lag or distance classes having a small number of pairs, while the remaining classes have a large number of pairs. By adjusting the value of the LAGDISTANCE= option to honor the rule of thumb (at least 30 pairs), you are “wasting” pairs in the other distance classes.

One strategy for solving this problem is to use less than 30 pairs for these distance classes. Then, either delete the corresponding variogram points or use them and accept the increased uncertainty. Unfortunately, the deficient distance classes are usually those close to the origin (\(h = 0\)). This is the crucial portion of the experimental variogram curve for determining the form of the theoretical variogram and for detecting the presence of a nugget effect.

Another alternative is to force distance classes to contain approximately the same number of pairs. This results in distance classes of unequal widths.

While PROC VARIOGRAM does not produce such distance classes directly, the OUTPAIR= data set, described in the section “OUTPAIR=SAS-data-set” on page 4881, contains information on all distinct pairs of points. You can use this data set,
along with the RANK procedure, to produce experimental variogram-based equal
tables of pairs in each distance class.

To request an OUTDIST= data set, you specify the OUTDIST= data set in the PROC
VARIOGRAM statement and the NOVARIOGRAM option in the COMPUTE state-
ment. The NOVARIOGRAM option prevents any variogram or covariance computa-
tion from being performed.

**Computation of the Distribution Distance Classes**

The simplest way of determining the distribution of pairwise distances is to determine
the maximum distance $h_{\text{max}}$ between pairs and divide this distance by some number
$N$ of intervals to produce distance classes of length $\delta = \frac{h_{\text{max}}}{N}$. The distance between
each pair of points $P_1, P_2$, denoted $|P_1P_2|$, is computed, and the pair $P_1P_2$ is
counted in the $k$th distance class if $|P_1P_2| \in [(k - 1)\delta, k\delta)$ for $k = 1, \cdots, N$.

The actual computation is a slight variation of this. A bound, rather than the ac-
tual maximum distance, is computed. This bound is the length of the diagonal of a
bounding rectangle for the data points. This bounding rectangle is found by using the
maximum and minimum $x$ and $y$ coordinates, $x_{\text{max}}, x_{\text{min}}, y_{\text{max}}, y_{\text{min}}$, and forming
the rectangle determined by the points

$$(x_{\text{max}}, y_{\text{max}}), (x_{\text{max}}, y_{\text{min}}), (x_{\text{min}}, y_{\text{min}}), (x_{\text{min}}, y_{\text{max}})$$

See Figure 80.16 for an illustration of the bounding rectangle.

![Figure 80.16. Bounding Rectangle to Determine Maximum Pairwise Distance](image)

The pairwise distance bound, denoted by $h_b$, is given by

$$h_b^2 = (x_{\text{max}} - x_{\text{min}})^2 + (y_{\text{max}} - y_{\text{min}})^2$$
Using \( h_0 \), the interval \((0, h_b]\) is divided into \( N + 1 \) subintervals, where \( N \) is the value of the NHCLASSES= option specified in the COMPUTE statement, or \( N = 10 \) if the NHCLASSES= option is not specified. The basic distance unit is \( h_0 = \frac{h_b}{N} \); the distance intervals are centered on \( h_0, 2h_0, \cdots, Nh_0 \), with a distance tolerance of \( \pm \frac{h_0}{2} \). The extra subinterval is \((0, h_0/2)\), corresponding to the 0th lag. It is half the length of the remaining subintervals, and it often contains the smallest number of pairs.

This method of partitioning the interval \((0, h_b]\) is identical to what is done when you actually compute the sample variogram.

The lag classes corresponding to \( h_0 = 1 \) are shown in Figure 80.17.

![Figure 80.17. Lag Classes Corresponding to \( h_0 = 1 \)](image)

By increasing or decreasing the value of the NHCLASSES= option, you can adjust the lag or distance class with the smallest count so that this count is around 30 or some other value that you judge appropriate.

Once you determine an appropriate value for the NHCLASSES= option, you can use the width of the lag classes as a candidate value for the LAGDIST= option in the COMPUTE statement. The width of the lag classes is determined by the upper bound (UB) and lower bound (LB) variables.

For example, read the observation from the OUTDIST= data set corresponding to lag 1 and compute the quantity UB-LB. Use this value for the LAGDIST= option in the COMPUTE statement.

**Note:** Do not use the 0th lag class; it is half the length of the other intervals. Use lag 1 instead.

**Variables in the OUTDIST= data set**

The following variables are written to the OUTDIST= data set:

- **COUNT**, which is the number of pairs falling into this lag class
- **LAG**, which is the lag class value
- **LB**, which is the lower bound of the lag class interval
- **UB**, which is the upper bound of the lag class interval
- **PER**, which is the percent of all pairs falling in this lag class
- **VARNAME**, which is the name of the current VAR= variable
The OUTPAIR= data set contains one observation for each distinct pair of points $P_1, P_2$ in the original data set, unless you specify the OUTPDISTANCE= option in the COMPUTE statement.

If you specify OUTPDISTANCE=$D_{max}$ in the COMPUTE statement, all pairs $P_1, P_2$ in the original data set that satisfy the relation $|P_1P_2| \leq D_{max}$ are written to the OUTPAIR= data set.

Note that the OUTPAIR= data set can be very large even for a moderately sized DATA= data set. For example, if the DATA= data set has NOBS=500, the OUTPAIR= data set has NOBS(NOBS − 1)/2 = 124,750 if no OUTPDISTANCE= restriction is given in the COMPUTE statement.

The OUTPAIR= data set contains information on the distance and orientation for each point pair, and you can use it for specialized continuity measure calculations.

The OUTPAIR= data set contains the following variables:

- AC, which is the angle class value
- COS, which is the cosine of the angle between pairs
- DC, which is the distance (lag) class
- DISTANCE, which is the distance between pairs
- V1, which is the variable value for the first point in the pair
- V2, which is the variable value for the second point in the pair
- VARNAME, which is the variable name for the current VAR variable
- X1, which is the $x$ coordinate of the first point in the pair
- X2, which is the $x$ coordinate of the second point in the pair
- Y1, which is the $y$ coordinate of the first point in the pair
- Y2, which is the $y$ coordinate of the second point in the pair

Computational Resources

The computations of the VARIOGRAM procedure are basically binning: for each pair of observations in the input data set, a distance and angle class is determined and recorded. Let $N_d$ denote the number of distance classes, $N_a$ denote the number of angle classes, and $N_v$ denote the number of VAR variables. The memory requirements for these operations are proportional to $N_d \times N_a \times N_v$. This is typically small.

The CPU time required for the computations is proportional to the number of pairs of observations, or to $N^2 \times N_v$, where $N$ is the number of observations in the input data set.
Example

Example 80.1. A Box Plot of the Square Root Difference Cloud

The Gaussian form chosen for the variogram in the “Getting Started” section on page 4852 is based on the consideration of the plots of the sample variogram. For the coal thickness data, the Gaussian form appears to be a reasonable choice.

It can often happen, however, that a plot of the sample variogram shows so much scatter that no particular form is evident. The cause of this scatter can be one or more outliers in the pairwise differences of the measured quantities.

A method of identifying potential outliers is discussed in Cressie (1993, section 2.2.2). This example illustrates how to use the OUTPAIR= data set from PROC VARIOGRAM to produce a square root difference cloud, which is useful in detecting outliers.

For the spatial process $Z(s), s \in \mathbb{R}^2$, the square root difference cloud for a particular direction $e$ is given by

$$|Z(s_i + he) - Z(s_i)|^{1/2}$$

for a given lag distance $h$. In the actual computation, all pairs of points $P_1, P_2$ within a distance tolerance around $h$ and an angle tolerance around the direction $e$ are used. This generates a number of point pairs for each lag class $h$. The spread of these values gives an indication of outliers.

Following the example in the “Getting Started” section on page 4852, this example uses a basic lag distance of 7 units, with a distance tolerance of 3.5, and a direction of N–S, with a 30° angle tolerance.

First, input the data, then use PROC VARIOGRAM to produce an OUTPAIR= data set. Then use a DATA step to subset this data by choosing pairs within 30° of N–S. In addition, compute lag class and square root difference variables. Next, summarize the results using the MEANS procedure and present them in a box plot using the SHEWHART procedure. The box plot facilitates the detection of outliers.

You can conclude from this example that there does not appear to be any outliers in the N–S direction for the coal seam thickness data.

Appendix A
Special SAS Data Sets

Introduction to Special SAS Data Sets

All SAS/STAT procedures create SAS data sets. Any table generated by a procedure can be saved to a data set by using the Output Delivery System (ODS), and many procedures also have syntax to enable you to save other statistics to data sets. Some of these data sets are organized according to certain conventions that allow them to be read by a SAS/STAT procedure for further analysis. Such specially organized data sets are recognized by the TYPE= attribute of the data set.

For example, the CORR procedure (refer to the SAS Procedures Guide) can create a data set with the attribute TYPE=CORR containing a correlation matrix. This TYPE=CORR data set can be read by the REG or FACTOR procedure, among others. If the original data set is large, using a special SAS data set in this way can save a great deal of computer time by avoiding the recomputation of the correlation matrix in each of several analyses.

As another example, the REG procedure can create a TYPE=EST data set containing estimated regression coefficients. If you need to make predictions for new observations, you can have the SCORE procedure read both the TYPE=EST data set and a data set containing the new observations. PROC SCORE can then compute predicted values or residuals without repeating the entire regression analysis. See Chapter 64, “The SCORE Procedure,” for an example.

A special SAS data set may contain different kinds of statistics. A special variable called _TYPE_ is used to distinguish the various statistics. For example, in a TYPE=CORR data set, an observation in which _TYPE_='MEAN' contains the means of the variables in the analysis, and an observation in which _TYPE_='STD' contains the standard deviations. Correlations appear in observations with _TYPE_='CORR'. Another special variable, _NAME_, is needed to identify the row of the correlation matrix. Thus, the correlation between variables X and Y would be given by the value of the variable X in the observation for which _TYPE_='CORR' and _NAME_='Y', or by the value of the variable Y in the observation for which _TYPE_='CORR' and _NAME_='X'.

You can create special SAS data steps directly in a DATA step by specifying the TYPE= option in parentheses after the data set name in the DATA statement. See Example A.2 on page 4896 for an example.

The special data sets created by SAS/STAT procedures can generally be used directly by other procedures without modification. However, if you create an output data set with PROC CORR and use the NOCORR option to omit the correlation matrix from the OUT= data set, you need to set the TYPE= option either in parentheses following the OUT= data set name in the PROC CORR statement or in parentheses following
the DATA= option in any other procedure that recognizes the special TYPE= attribute.
In either case, the TYPE= option should be set to COV, CSSCP, or SSCP according
to what type of matrix is stored in the data set and what data set types are accepted
as input by the other procedures you plan to use. If you do not follow these steps
and you use the TYPE=CORR data set with no correlation matrix as input to another
procedure, the procedure may issue an error message indicating that the correlation
matrix is missing from the data set.

If you use a DATA step with a SET statement to modify a special SAS data set, you
must specify the TYPE= option in the DATA statement. The TYPE= attribute of the
data set in the SET statement is not automatically copied to the data set being created.

You can determine the TYPE= attribute of a data set by using the CONTENTS pro-
procedure (see Example A.1 on page 4895 and refer to the SAS Procedures Guide for
details).

Table A.1 summarizes the TYPE= data sets that can be used as input to SAS/STAT
procedures and the TYPE= data sets that are created by SAS/STAT procedures. The
essential parts of the statements each procedure uses to create its output data set or
data sets are shown.

Formulas useful for illustrating differences between corrected and uncorrected matri-
ces in some special SAS data sets are shown in the “Definitional Formulas” section
on page 4902.

*If no TYPE= is shown, the procedure does not recognize any special data set types except possibly to issue an error message for inappropriate values of TYPE=.

Special SAS Data Sets

TYPE=CORR Data Sets

A TYPE=CORR data set usually contains a correlation matrix and possibly other statistics including means, standard deviations, and the number of observations in the original SAS data set from which the correlation matrix was computed.

Using PROC CORR with an output data set option (OUTP=, OUTS=, OUTK=, OUTH=, or OUT=) produces a TYPE=CORR data set. (For a complete description of the CORR procedure, refer to the SAS Procedures Guide). The CALIS, CANCORR, CANDISC, DISCRIM, PRINCOMP, and VARCLUS procedures can also create a TYPE=CORR data set with additional statistics.

A TYPE=CORR data set containing a correlation matrix can be used as input for the ACECLUS, CALIS, CANCORR, CANDISC, DISCRIM, FACTOR, PRINCOMP, REG, SCORE, STEPDISC, and VARCLUS procedures.
The variables in a TYPE=CORR data set are

- the BY variable or variables, if a BY statement is used with the procedure
- _TYPE_, a character variable of length eight with values identifying the type of statistic in each observation, such as 'MEAN', 'STD', 'N', and 'CORR'
- _NAME_, a character variable with values identifying the variable with which a given row of the correlation matrix is associated
- other variables that were analyzed by the CORR procedure or other procedures

The usual values of the _TYPE_ variable are as follows.

<table>
<thead>
<tr>
<th><em>TYPE</em></th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEAN</td>
<td>mean of each variable analyzed</td>
</tr>
<tr>
<td>STD</td>
<td>standard deviation of each variable</td>
</tr>
<tr>
<td>N</td>
<td>number of observations used in the analysis. PROC CORR records the number of nonmissing values for each variable unless the NOMISS option is used. If the NOMISS option is specified, or if the CALIS, CANCORR, CANDISC, PRINCOMP, or VARCLUS procedure is used to create the data set, observations with one or more missing values are omitted from the analysis, so this value is the same for each variable and provides the number of observations with no missing values. If a FREQ statement is used with the procedure that creates the data set, the number of observations is the sum of the relevant values of the variable in the FREQ statement. Procedures that read a TYPE=CORR data set use the smallest value in the observation with <em>TYPE</em>='N' as the number of observations in the analysis.</td>
</tr>
<tr>
<td>SUMWGT</td>
<td>sum of the observation weights if a WEIGHT statement is used with the procedure that creates the data set. The values are determined analogously to those of the <em>TYPE</em>='N' observation.</td>
</tr>
<tr>
<td>CORR</td>
<td>correlations with the variable named by the <em>NAME</em> variable</td>
</tr>
</tbody>
</table>

There may be additional observations in a TYPE=CORR data set depending on the particular procedure and options used.

If you create a TYPE=CORR data set yourself, the data set need not contain the observations with _TYPE_='MEAN', 'STD', 'N', or 'SUMWGT', unless you intend to use one of the discriminant procedures. Procedures assume that all of the means are 0.0 and that the standard deviations are 1.0 if this information is not in the TYPE=CORR data set. If _TYPE_='N' does not appear, most procedures assume that the number of observations is 10,000; significance tests and other statistics that depend on the number of observations are, of course, meaningless. In the CALIS and CANCORR procedures, you can use the EDF= option instead of including a _TYPE_='N' observation.
A correlation matrix is symmetric; that is, the correlation between X and Y is the same as the correlation between Y and X. The CALIS, CANCORR, CANDISC, CORR, DISCRIM, PRINCOMP, and VARCLUS procedures output the entire correlation matrix. If you create the data set yourself, you need to include only one of the two occurrences of the correlation between two variables; the other may be given a missing value.

If you create a TYPE=CORR data set yourself, the _TYPE_ and _NAME_ variables are not necessary except for use with the discriminant procedures and PROC SCORE. If there is no _TYPE_ variable, then all observations are assumed to contain correlations. If there is no _NAME_ variable, the first observation is assumed to correspond to the first variable in the analysis, the second observation to the second variable, and so on. However, if you omit the _NAME_ variable, you will not be able to analyze arbitrary subsets of the variables or list the variables in a VAR or MODEL statement in a different order.

**Example A.1: A TYPE=CORR Data Set Produced by PROC CORR**

See Output A.1.1 for an example of a TYPE=CORR data set produced by the following SAS statements. Output A.1.2 displays partial output from the CONTENTS procedure, which indicates that the “Data Set Type” is ’CORR’.

**TYPE=UCORR Data Sets**

A TYPE=UCORR data set is almost identical to a TYPE=CORR data set, except that the correlations are uncorrected for the mean. The corresponding value of the _TYPE_= variable is ‘UCORR’ instead of ‘CORR’. Uncorrected standard deviations are in observations with _TYPE_='USTD'.

A TYPE=UCORR data set can be used as input for every SAS/STAT procedure that uses a TYPE=CORR data set, except for the CANDISC, DISCRIM, and STEPDISC procedures. TYPE=UCORR data sets can be created by the CALIS, CANCORR, PRINCOMP, and VARCLUS procedures.

**TYPE=COV Data Sets**

A TYPE=COV data set is similar to a TYPE=CORR data set except that it has _TYPE_='COV' observations containing covariances instead of or in addition to _TYPE_='CORR' observations containing correlations. The CALIS and PRINCOMP procedures create a TYPE=COV data set if the COV option is used. You can also create a TYPE=COV data set by using PROC CORR with the COV and NOCORR options and specifying the data set option TYPE=COV in parentheses following the name of the output data set. You can use only the OUTP= or OUT= options to create a TYPE=COV data set with PROC CORR.

Another way to create a TYPE=COV data set is to read a covariance matrix in a data set, in the same manner as shown in Example A.2 on page 4896 for a TYPE=CORR data set.

TYPE=COV data sets are used by the same procedures that use TYPE=CORR data sets.
**TYPE=UCOV Data Sets**

A TYPE=UCOV data set is similar to a TYPE=COV data set, except that the covariances are uncorrected for the mean. Also, the corresponding value of the _TYPE_ variable is 'UCOV' instead of 'COV'.

A TYPE=UCOV data set can be used as input for every SAS/STAT procedure that uses a TYPE=COV data set, except for the CANDISC, DISCRIM, and STEPDISC procedures. TYPE=UCOV data sets can be created by the CALIS and PRINCOMP procedures.

**TYPE=SSCP Data Sets**

A TYPE=SSCP data set contains an uncorrected sum of squares and crossproducts (SSCP) matrix. TYPE=SSCP data sets are produced by PROC REG when the OUTSSCP= option is specified in the PROC REG statement. You can also create a TYPE=SSCP data set by using PROC CORR with the SSCP option and specifying the data set option TYPE=SSCP in parentheses following the name of the OUTP= or OUT= data set. You can also create TYPE=SSCP data sets in a DATA step; in this case, TYPE=SSCP must be specified as a data set option.

The variables in a TYPE=SSCP data set include those found in a TYPE=CORR data set. In addition, there is a variable called Intercept that contains crossproducts for the intercept (sums of the variables). The SSCP matrix is stored in observations with _TYPE_='SSCP', including a row with _NAME_='Intercept'. PROC REG also outputs an observation with _TYPE_='N'. PROC CORR includes observations with _TYPE_='MEAN' and _TYPE_='STD' as well.

TYPE=SSCP data sets are used by the same procedures that use TYPE=CORR data sets.

**Example A.3: A TYPE=SSCP Data Set Produced by PROC REG**

Output A.3.1 shows a TYPE=SSCP data set produced by PROC REG from the SocEcon data set created in Example A.1 on page 4895.

```sas
proc reg data=SocEcon outsscp=regsscp;
   model house=pop school employ services / noprint;
run;

proc print data=regsscp;
run;
```

TYPE=CSSCP Data Sets

A TYPE=CSSCP data set contains a corrected sum of squares and crossproducts (CSSCP) matrix. TYPE=CSSCP data sets are created by using the CORR procedure with the CSSCP option and specifying the data set option TYPE=CSSCP in parentheses following the name of the OUTP= or OUT= data set. You can also create TYPE=CSSCP data sets in a DATA step; in this case, TYPE=CSSCP must be specified as a data set option.

The variables in a TYPE=CSSCP data set are the same as those found in a TYPE=SSCP data set, except that there is not a variable called Intercept or a row with _NAME_='Intercept'.

TYPE=CSSCP data sets are read by only the CANDISC, DISCRIM, and STEPDISC procedures.

TYPE=EST Data Sets

A TYPE=EST data set contains parameter estimates. The CALIS, CATMOD, LIFEREG, LOGISTIC, NLIN, ORTHOREG, PHREG, PROBIT, and REG procedures create TYPE=EST data sets when the OUTEST= option is specified. A TYPE=EST data set produced by PROC LIFEREG, PROC ORTHOREG, or PROC REG can be used with PROC SCORE to compute residuals or predicted values.

The variables in a TYPE=EST data set include

- the BY variables, if a BY statement is used
- _TYPE_, a character variable of length eight, that indicates the type of estimate. The values depend on which procedure created the data set. Usually a value of ‘PARM’ or ‘PARMS’ indicates estimated regression coefficients, and a value of ‘COV’ or ‘COVB’ indicates estimated covariances of the parameter estimates. Some procedures, such as PROC NLIN, have other values of _TYPE_ for special purposes.
- _NAME_, a character variable that contains the values of the names of the rows of the covariance matrix when the procedure outputs the covariance matrix of the parameter estimates.
- variables that contain the parameter estimates, usually the same variables that appear in the VAR statement or in any MODEL statement. See Chapter
Appendix A. Special SAS Data Sets

Other variables can be included depending on the particular procedure and options used.

**Example A.4: A TYPE=EST Data Set Produced by PROC REG**

Output A.4.1 shows the TYPE=EST data set produced by the following statements:

```
proc reg data=SocEcon outest=regest covout;
  full: model house=pop school employ services / noprint;
  empser: model house=employ services / noprint;
run;
proc print data=regest;
run;
```

**TYPE=ACE Data Sets**

A TYPE=ACE data set is created by the ACECLUS procedure, and it contains the approximate within-cluster covariance estimate, as well as eigenvalues and eigenvectors from a canonical analysis, among other statistics. It can be used as input to the ACECLUS procedure to initialize another execution of PROC ACECLUS. It can also be used to compute canonical variable scores with the SCORE procedure and as input to the FACTOR procedure, specifying METHOD=SCORE, to rotate the canonical variables. See Chapter 16, “The ACECLUS Procedure,” for details.
**TYPE=WEIGHT Data Sets**

The CALIS procedure creates and accepts as input a TYPE=WEIGHT data set. This data set contains the weight matrix used in generalized, weighted, or diagonally weighted least-squares estimation. See Chapter 19, “The CALIS Procedure,” for details.

**TYPE=DISTANCE Data Sets**

You can create a TYPE=DISTANCE data set containing distance or dissimilarity measures using the DISTANCE procedure. The proximity measures are stored as a lower triangular matrix or a square matrix in the OUT= data set (depending on the SHAPE= option). See Chapter 26, “The DISTANCE Procedure,” for details. You can also create a TYPE=DISTANCE data set in a DATA step by reading or computing a lower triangular or symmetric matrix of dissimilarity values, such as a chart of mileage between cities. The number of observations must be equal to the number of variables used in the analysis. This type of data set is used as input by the CLUSTER and MODECLUS procedures. PROC CLUSTER ignores the upper triangular portion of a TYPE=DISTANCE data set and assumes that all main diagonal values are zero, even if they are missing. PROC MODECLUS uses the entire distance matrix and does not require the matrix to be symmetric. See Chapter 23, “The CLUSTER Procedure,” and Chapter 47, “The MODECLUS Procedure,” for examples and details.

**TYPE=FACTOR Data Sets**

A TYPE=FACTOR data set is created by PROC FACTOR when the OUTSTAT= option is specified. The CALIS, CANCORR, FACTOR, PRINCOMP, SCORE, and VARCLUS procedures can use TYPE=FACTOR data sets as input. The variables are the same as in a TYPE=CORR data set. The statistics include means, standard deviations, sample size, correlations, eigenvalues, eigenvectors, factor patterns, residual correlations, scoring coefficients, and others depending on the options specified. See Chapter 27, “The FACTOR Procedure,” for details.

When the NOINT option is used with the OUTSTAT= option in PROC FACTOR, the value of the _TYPE_ variable is set to 'USCORE' instead of 'SCORE' to indicate that the scoring coefficients have not been corrected for the mean. If this data set is used with the SCORE procedure, the value of the _TYPE_ variable tells PROC SCORE whether or not to subtract the mean from the scoring coefficients.

**TYPE=RAM Data Sets**

The CALIS procedure creates and accepts as input a TYPE=RAM data set. This data set contains the model specification and the computed parameter estimates. A TYPE=RAM data set is intended to be reused as an input data set to specify good initial values in subsequent analyses by PROC CALIS. See Chapter 19, “The CALIS Procedure,” for details.
TYPE=LINEAR Data Sets

A TYPE=LINEAR data set contains the coefficients of a linear function of the variables in observations with _TYPE_='LINEAR'.

The DISCRIM procedure stores linear discriminant function coefficients in a TYPE=LINEAR data set when you specify METHOD=NORMAL (the default method), POOL=YES, and an OUTSTAT= data set; the data set can be used in a subsequent invocation of PROC DISCRIM to classify additional observations. Many other statistics can be included depending on the options used. See Chapter 25, “The DISCRIM Procedure,” for details.

TYPE=QUAD Data Sets

A TYPE=QUAD data set contains the coefficients of a quadratic function of the variables in observations with _TYPE_='QUAD'.

The DISCRIM procedure stores quadratic discriminant function coefficients in a TYPE=QUAD data set when you specify METHOD=NORMAL (the default method), POOL=NO, and an OUTSTAT= data set; the data set can be used in a subsequent invocation of PROC DISCRIM to classify additional observations. Many other statistics can be included depending on the options used. See Chapter 25, “The DISCRIM Procedure,” for details.

TYPE=MIXED Data Sets

A TYPE=MIXED data set contains coefficients of either a linear or a quadratic function, or both if there are BY groups.

The DISCRIM procedure produces a TYPE=MIXED data set when you specify METHOD=NORMAL (the default method), POOL=TEST, and an OUTSTAT= data set. See Chapter 25, “The DISCRIM Procedure,” for details.

Definitional Formulas

This section contrasts corrected and uncorrected SSCP, COV, and CORR matrices by showing how these matrices can be computed.

In the following formulas, assume that the data consist of two variables, X and Y, with n observations.

\[
\text{SSCP} = \begin{bmatrix}
\sum X & \sum X^2 & \sum XY \\
\sum Y & \sum XY & \sum Y^2 \\
\end{bmatrix}
\]

\[
\text{CSSCP} = \begin{bmatrix}
\sum (X - \bar{X})^2 \\
\sum (X - \bar{X})(Y - \bar{Y}) \\
\sum (Y - \bar{Y})^2 \\
\end{bmatrix}
\]
\[
\text{COV} = \frac{\text{CSSCP}}{n - 1} = \frac{1}{n - 1} \left[ \frac{\sum (X - \bar{X})^2}{\sum (X - \bar{X})(Y - \bar{Y})} \right] \frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sum (Y - \bar{Y})^2} \\
\text{UCOV} = \frac{1}{n} \left[ \frac{\sum X^2}{\sum XY} \right] \frac{\sum XY}{\sum Y^2} \\
\text{CORR} = \left[ \begin{array}{cc} 1 & \frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum (X - \bar{X})^2 \sum (Y - \bar{Y})^2}} \\
\frac{\sum (X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum (X - \bar{X})^2 \sum (Y - \bar{Y})^2}} & 1 
\end{array} \right] \\
\text{UCORR} = \left[ \begin{array}{cc} 1 & \frac{\sum XY}{\sqrt{\sum X^2 \sum Y^2}} \\
\frac{\sum XY}{\sqrt{\sum X^2 \sum Y^2}} & 1 
\end{array} \right]
\]

Appendix B
Using the %PLOTIT Macro

Overview

You can use the PLOT procedure to create low-resolution printer plots of labeled points. Alternatively, you can use the %PLOTIT macro to create high-resolution graphical scatter plots of labeled points.

The %PLOTIT macro is designed to make it easy to display raw data, regression results, and results from the CORRESP, MDS, PRINCOMP, PRINQUAL, and TRANSREG procedures. You can use this macro to position labels, draw curves, vectors, and circles, and shade to show density or a third variable. You can also use the %PLOTIT macro to control the colors, sizes, fonts, and general appearance of the plots and to create contour plots for discriminant analysis.

The %PLOTIT macro is a part of the SAS autocall library. If your site has installed the autocall libraries supplied by SAS Institute and uses the standard configuration of SAS software supplied by the Institute, you need only to ensure that the SAS system option MAUTOSOURCE is in effect to begin using the autocall macros.

%PLOTIT Macro Options Used in This Book

Most of the examples in this book that invoke the %PLOTIT macro are created with a specific set of options. The graphics are generated by using a special macro variable called plotitop.

The code you see in the examples creates the color graphics that appear in the online (CD) version of the manual. A slightly different set of options and statements are used to create the black-and-white graphics that appear in the printed version of the book.

To create the online (color) version of the graphic output, the plotitop variable is defined as follows.
%let plotitop = gopts = gsfmode = replace
gaccess = gsasfile device = gif
hsiz3 = 5.63 vsiz3 = 3.5
cback = white,
cframe = ligr,
color = black,
colors = red blue white,
options = noclip expand, post=myplot.gif;

To create the black-and-white version of the graphic output, which appears in the printed version of the manual, the plotitop variable is defined as follows:

%let plotitop = gopts = gsfmode = replace
gaccess = gsasfile device = pslepsf
hsiz3 = 5.63 vsiz3 = 3.5
cback = white,
color = black,
colors = black,
options = noclip border expand, post=myplot.ps;

For information on graphics options used in other examples, see Chapter 1, “Introduction.”

  NPAR1WAY procedure, 3168
ante-dependence structure
  MIXED procedure, 2721
apparent error rate, 1163
approximate covariance, options (CALIS), 621
  standard errors (CALIS), 576, 587, 648, 686
approximate Bayesian bootstrap
  MI procedure, 2543
approximate covariance estimation
  clustering, 387
arbitrary missing pattern
  MI procedure, 2539
arcsine-square root transform
  LIFETEST procedure, 2205
arcsine-square root transformation
  LIFETEST procedure, 2169, 2177
arrays
  NLMIXED procedure, 3074
association tests
  LIFETEST procedure, 2150, 2156, 2200
association, measures of
  FREQ procedure, 1474
asterisk (*) operator
  TRANSREG procedure, 4558
asymmetric
  data (MDS), 2484
  binary variable
  DISTANCE procedure, 1250
asymmetric lambda, 1474, 1482
asymptotic covariance
  CALIS procedure, 575, 645
  MIXED procedure, 2674
asymptotic variances
  CALIS procedure, 647
asymptotically distribution free estimation
  CALIS procedure, 574, 646
at sign (@) operator
  ANOVA procedure, 452
  CATMOD procedure, 865
  GENMOD procedure, 1660
  GLM procedure, 1786
  MIXED procedure, 2743, 2745, 2819
  TRANSREG procedure, 4558
autocorrelation
  REG procedure, 3915
  MI procedure, 2557
autoregressive structure
  example (MIXED), 2788
  MIXED procedure, 2721
average linkage
  CLUSTER procedure, 966, 976
average relative increase in variance
  MIANALYZE procedure, 2627
average variance of means
  LATTICE procedure, 2074
axes labels, modifying
  examples, ODS Graphics, 368

B
B-spline basis
  TRANSREG procedure, 4560, 4614
backward elimination
  LOGISTIC procedure, 2317, 2340
  PHREG procedure, 3229, 3264
  REG procedure, 3800, 3874
badness of fit
  MDS procedure, 2479, 2482, 2483, 2489, 2490
balanced data
  ANOVA procedure, 423
  example, complete block, 1847
balanced design, 2985
balanced square lattice
  LATTICE procedure, 2069
banded Toeplitz structure
  MIXED procedure, 2721
bandwidth
  optimal (DISCRIM), 1162
  selection (KDE), 2008
  VARIOGRAM procedure, 4866, 4870, 4875
