\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{f(\theta + h_i e_i + h_j e_j) - f(\theta + h_i e_i) - f(\theta + h_j e_j) + f(\theta)}{h_i h_j}
\]

For second-order derivatives based on gradient calls (Dennis and Schnabel 1983, p. 103), \( n \) additional gradient calls are required:

\[
\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{g_i(\theta + h_j e_j) - g_i(\theta)}{2h_j} + \frac{g_j(\theta + h_i e_i) - g_j(\theta)}{2h_i}
\]

Central Difference Approximations

Central difference approximations are usually more precise, but they consume more computer time than approximations that use forward difference derivative formulas.

For first-order derivatives, \( 2n \) additional function calls are required:

\[
g_i = \frac{\partial f}{\partial \theta_i} \approx \frac{f(\theta + 2h_i e_i) - f(\theta - h_i e_i)}{2h_i}
\]

For second-order derivatives based on function calls only (Abramowitz and Stegun 1972, p. 884), \( 2n + 4n^2 / 2 \) additional function calls are required.

\[
\frac{\partial^2 f}{\partial \theta_i^2} \approx \frac{-f(\theta + 2h_i e_i) + 16f(\theta + h_i e_i) - 30f(\theta) + 16f(\theta - h_i e_i) - f(\theta - 2h_i e_i)}{12h_i^2}
\]

\[
\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{f(\theta + h_i e_i + h_j e_j) - f(\theta + h_i e_i - h_j e_j) - f(\theta - h_i e_i + h_j e_j) + f(\theta - h_i e_i - h_j e_j)}{4h_i h_j}
\]

For second-order derivatives based on gradient calls, \( 2n \) additional gradient calls are required:

\[
\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{g_i(\theta + h_j e_j) - g_i(\theta - h_j e_j)}{4h_j} + \frac{g_j(\theta + h_i e_i) - g_j(\theta - h_i e_i)}{4h_i}
\]

You can use the FDIGITS= option to specify the number of accurate digits in the evaluation of the objective function. This specification is helpful in determining an appropriate interval size \( h \) to be used in the finite difference formulas.

The step sizes \( h_j, j = 1, \ldots, n \) are defined as follows.

For the forward difference approximation of first-order derivatives using function calls and second-order derivatives using gradient calls, \( h_j = \frac{\sqrt{7}}{7}(1 + |\theta_j|) \).
• For the forward difference approximation of second-order derivatives using only function calls and all central difference formulas, 
  \[ h_j = \sqrt[3]{\eta(1 + |\theta_j|)} \].

The value of \( \eta \) is defined by the FDIGITS= option:

• If you specify the number of accurate digits using FDIGITS=r, \( \eta \) is set to \( 10^{-r} \).
• If you do not specify the FDIGITS= option, \( \eta \) is set to the machine precision \( \epsilon \).

**Hessian Scaling**

The rows and columns of the Hessian matrix can be scaled when you use the trust region, Newton-Raphson, and double dogleg optimization techniques. Each element \( H_{i,j} \), \( i, j = 1, \ldots, n \) is divided by the scaling factor \( d_i d_j \), where the scaling vector \( d = (d_1, \ldots, d_n) \) is iteratively updated in a way specified by the HESCAL=i option, as follows.

\[ i = 0 : \text{No scaling is done (equivalent to } d_i = 1). \]

\[ i \neq 0 : \text{First iteration and each restart iteration sets:} \]

\[ d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)} \]

\[ i = 1 : \text{Refer to Moré (1978):} \]

\[ d_i^{(k+1)} = \max\left[ d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right] \]

\[ i = 2 : \text{Refer to Dennis, Gay, and Welsch (1981):} \]

\[ d_i^{(k+1)} = \max\left[ 0.6 d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right] \]

\[ i = 3 : d_i \text{ is reset in each iteration:} \]

\[ d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \]

In the preceding equations, \( \epsilon \) is the relative machine precision or, equivalently, the largest double precision value that, when added to 1, results in 1.

**Active Set Methods**

The parameter vector \( \theta \in \mathbb{R}^n \) can be subject to a set of \( m \) linear equality and inequality constraints:

\[ \sum_{j=1}^{n} a_{ij} \theta_j = b_i \quad i = 1, \ldots, m_e \]

\[ \sum_{j=1}^{n} a_{ij} \theta_j \geq b_i \quad i = m_e + 1, \ldots, m \]
The coefficients $a_{ij}$ and right-hand sides $b_i$ of the equality and inequality constraints are collected in the $m \times n$ matrix $A$ and the $m$ vector $b$.

The $m$ linear constraints define a feasible region $\mathcal{G}$ in $\mathbb{R}^n$ that must contain the point $\theta_*$ that minimizes the problem. If the feasible region $\mathcal{G}$ is empty, no solution to the optimization problem exists.

In PROC NLMIXED, all optimization techniques use active set methods. The iteration starts with a feasible point $\theta^{(0)}$, which you can provide or which can be computed by the Schittkowski and Stoer (1979) algorithm implemented in PROC NLMIXED. The algorithm then moves from one feasible point $\theta^{(k-1)}$ to a better feasible point $\theta^{(k)}$ along a feasible search direction $s^{(k)}$:

$$\theta^{(k)} = \theta^{(k-1)} + \alpha^{(k)} s^{(k)}, \quad \alpha^{(k)} > 0$$

Theoretically, the path of points $\theta^{(k)}$ never leaves the feasible region $\mathcal{G}$ of the optimization problem, but it can reach its boundaries. The active set $\mathcal{A}^{(k)}$ of point $\theta^{(k)}$ is defined as the index set of all linear equality constraints and those inequality constraints that are satisfied at $\theta^{(k)}$. If no constraint is active $\theta^{(k)}$, the point is located in the interior of $\mathcal{G}$, and the active set $\mathcal{A}^{(k)} = \emptyset$ is empty. If the point $\theta^{(k)}$ in iteration $k$ hits the boundary of inequality constraint $i$, this constraint $i$ becomes active and is added to $\mathcal{A}^{(k)}$. Each equality constraint and each active inequality constraint reduce the dimension (degrees of freedom) of the optimization problem.

In practice, the active constraints can be satisfied only with finite precision. The LCEPSILON= $r$ option specifies the range for active and violated linear constraints. If the point $\theta^{(k)}$ satisfies the condition

$$\left| \sum_{j=1}^{n} a_{ij} \theta_j^{(k)} - b_i \right| \leq t$$

where $t = r(|b_i| + 1)$, the constraint $i$ is recognized as an active constraint. Otherwise, the constraint $i$ is either an inactive inequality or a violated inequality or equality constraint. Due to rounding errors in computing the projected search direction, error can be accumulated so that an iterate $\theta^{(k)}$ steps out of the feasible region.

In those cases, PROC NLMIXED may try to pull the iterate $\theta^{(k)}$ back into the feasible region. However, in some cases the algorithm needs to increase the feasible region by increasing the LCEPSILON= $r$ value. If this happens, a message is displayed in the log output.

If the algorithm cannot improve the value of the objective function by moving from an active constraint back into the interior of the feasible region, it makes this inequality constraint an equality constraint in the next iteration. This means that the active set $\mathcal{A}^{(k+1)}$ still contains the constraint $i$. Otherwise, it releases the active inequality constraint and increases the dimension of the optimization problem in the next iteration.
A serious numerical problem can arise when some of the active constraints become (nearly) linearly dependent. PROC NLMIXED removes linearly dependent equality constraints before starting optimization. You can use the LCSINGULAR= option to specify a criterion used in the update of the QR decomposition that determines whether an active constraint is linearly dependent relative to a set of other active constraints.

If the solution $\theta^*$ is subjected to $n_{\text{act}}$ linear equality or active inequality constraints, the QR decomposition of the $n \times n_{\text{act}}$ matrix $\hat{A}^T$ of the linear constraints is computed by $\hat{A}^T = QR$, where $Q$ is an $n \times n$ orthogonal matrix and $R$ is an $n \times n_{\text{act}}$ upper triangular matrix. The $n$ columns of matrix $Q$ can be separated into two matrices, $Q = [Y, Z]$, where $Y$ contains the first $n_{\text{act}}$ orthogonal columns of $Q$ and $Z$ contains the last $n - n_{\text{act}}$ orthogonal columns of $Q$. The $n \times (n - n_{\text{act}})$ column-orthogonal matrix $Z$ is also called the nullspace matrix of the active linear constraints $\hat{A}^T$. The $n - n_{\text{act}}$ columns of the $n \times (n - n_{\text{act}})$ matrix $Z$ form a basis orthogonal to the rows of the $n_{\text{act}} \times n$ matrix $\hat{A}$.

At the end of the iterating, PROC NLMIXED computes the projected gradient $g_Z$,

$$g_Z = Z^T g$$

In the case of boundary-constrained optimization, the elements of the projected gradient correspond to the gradient elements of the free parameters. A necessary condition for $\theta^*$ to be a local minimum of the optimization problem is

$$g_Z(\theta^*) = Z^T g(\theta^*) = 0$$

The symmetric $n_{\text{act}} \times n_{\text{act}}$ matrix $G_Z$,

$$G_Z = Z^T G Z$$

is called a projected Hessian matrix. A second-order necessary condition for $\theta^*$ to be a local minimizer requires that the projected Hessian matrix is positive semidefinite. Those elements of the $n_{\text{act}}$ vector of first-order estimates of Lagrange multipliers,

$$\lambda = (\hat{A} \hat{A}^T)^{-1} \hat{A} Z Z^T g$$

that correspond to active inequality constraints indicate whether an improvement of the objective function can be obtained by releasing this active constraint. For minimization, a significant negative Lagrange multiplier indicates that a possible reduction of the objective function can be achieved by releasing this active linear constraint. The LCDEACT= $r$ option specifies a threshold $r$ for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. (In the case of boundary-constrained optimization, the Lagrange multipliers for active lower (upper) constraints are the negative (positive) gradient elements corresponding to the active parameters.)
Line-Search Methods

In each iteration $k$, the (dual) quasi-Newton, conjugate gradient, and Newton-Raphson minimization techniques use iterative line-search algorithms that try to optimize a linear, quadratic, or cubic approximation of $f$ along a feasible descent search direction $s^{(k)}$.

$$\theta^{(k+1)} = \theta^{(k)} + \alpha^{(k)} s^{(k)}, \quad \alpha^{(k)} > 0$$

by computing an approximately optimal scalar $\alpha^{(k)}$.

Therefore, a line-search algorithm is an iterative process that optimizes a nonlinear function $f(\alpha)$ of one parameter ($\alpha$) within each iteration $k$ of the optimization technique. Since the outside iteration process is based only on the approximation of the objective function, the inside iteration of the line-search algorithm does not have to be perfect. Usually, it is satisfactory that the choice of $\alpha$ significantly reduces (in a minimization) the objective function. Criteria often used for termination of line-search algorithms are the Goldstein conditions (refer to Fletcher 1987).

You can select various line-search algorithms by specifying the LIS= option. The line-search method LIS=2 seems to be superior when function evaluation consumes significantly less computation time than gradient evaluation. Therefore, LIS=2 is the default method for Newton-Raphson, (dual) quasi-Newton, and conjugate gradient optimizations.

You can modify the line-search methods LIS=2 and LIS=3 to be exact line searches by using the LSPRECISION= option and specifying the $\sigma$ parameter described in Fletcher (1987). The line-search methods LIS=1, LIS=2, and LIS=3 satisfy the left-hand side and right-hand side Goldstein conditions (refer to Fletcher 1987). When derivatives are available, the line-search methods LIS=6, LIS=7, and LIS=8 try to satisfy the right-hand side Goldstein condition; if derivatives are not available, these line-search algorithms use only function calls.

Restricting the Step Length

Almost all line-search algorithms use iterative extrapolation techniques that can easily lead them to (feasible) points where the objective function $f$ is no longer defined or difficult to compute. Therefore, PROC NLMIXED provides options restricting the step length $\alpha$ or trust region radius $\Delta$, especially during the first main iterations.

The inner product $g^T s$ of the gradient $g$ and the search direction $s$ is the slope of $f(\alpha) = f(\theta + \alpha s)$ along the search direction $s$. The default starting value $\alpha^{(0)} = \alpha^{(k,0)}$ in each line-search algorithm ($\min_{\alpha>0} f(\theta + \alpha s)$) during the main iteration $k$ is computed in three steps:

1. The first step uses either the difference $df = |f^{(k)} - f^{(k-1)}|$ of the function values during the last two consecutive iterations or the final step-size value $\alpha$– of the last iteration $k - 1$ to compute a first value of $\alpha^{(0)}_1$. 
• If the DAMPSTEP option is not used,

\[ \alpha_1^{(0)} = \begin{cases} 
  \text{step} & \text{if } 0.1 \leq \text{step} \leq 10 \\
  10 & \text{if } \text{step} > 10 \\
  0.1 & \text{if } \text{step} < 0.1 
\end{cases} \]

with

\[ \text{step} = \begin{cases} 
  \frac{df}{|g^T s|} & \text{if } |g^T s| \geq \epsilon \max(100df, 1) \\
  1 & \text{otherwise} 
\end{cases} \]

This value of \( \alpha_1^{(0)} \) can be too large and can lead to a difficult or impossible function evaluation, especially for highly nonlinear functions such as the EXP function.

• If the DAMPSTEP[=r] option is used,

\[ \alpha_1^{(0)} = \min(1, r\alpha^-) \]

The initial value for the new step length can be no larger than \( r \) times the final step length \( \alpha^- \) of the former iteration. The default value is \( r = 2 \).

2. During the first five iterations, the second step enables you to reduce \( \alpha_1^{(0)} \) to a smaller starting value \( \alpha_2^{(0)} \) using the INSTEP=r option:

\[ \alpha_2^{(0)} = \min(\alpha_1^{(0)}, r) \]

After more than five iterations, \( \alpha_2^{(0)} \) is set to \( \alpha_1^{(0)} \).

3. The third step can further reduce the step length by

\[ \alpha_3^{(0)} = \min(\alpha_2^{(0)}, \min(10, u)) \]

where \( u \) is the maximum length of a step inside the feasible region.

The INSTEP=r option enables you to specify a smaller or larger radius \( \Delta \) of the trust region used in the first iteration of the trust region and double dogleg algorithms. The default initial trust region radius \( \Delta^{(0)} \) is the length of the scaled gradient (Moré 1978). This step corresponds to the default radius factor of \( r = 1 \). In most practical applications of the TRUREG and DBLDOG algorithms, this choice is successful. However, for bad initial values and highly nonlinear objective functions (such as the EXP function), the default start radius can result in arithmetic overflows. If this happens, you can try decreasing values of INSTEP=r, \( 0 < r < 1 \), until the iteration starts successfully. A small factor \( r \) also affects the trust region radius \( \Delta^{(k+1)} \) of the next steps because the radius is changed in each iteration by a factor \( 0 < c \leq 4 \), depending on the ratio \( \rho \) expressing the goodness of quadratic function approximation. Reducing the radius \( \Delta \) corresponds to increasing the ridge parameter \( \lambda \), producing smaller steps directed more closely toward the (negative) gradient direction.
Computational Problems

Floating Point Errors and Overflows

Numerical optimization of a numerically integrated function is a difficult task, and the computation of the objective function and its derivatives can lead to arithmetic exceptions and overflows. A typical cause of these problems is parameters with widely varying scales. If the scaling of your parameters varies by more than a few orders of magnitude, the numerical stability of the optimization problem can be seriously reduced and result in computational difficulties. A simple remedy is to rescale each parameter so that its final estimated value has a magnitude near 1.

If parameter rescaling does not help, consider the following actions:

- Specify the ITDETAILS option in the PROC NLMIXED statement to obtain more detailed information about when and where the problem is occurring.
- Provide different initial values or try a grid search of values.
- Use boundary constraints to avoid the region where overflows may happen.
- Delete outlying observations or subjects from the input data, if this is reasonable.
- Change the algorithm (specified in programming statements) that computes the objective function.

The line-search algorithms that work with cubic extrapolation are especially sensitive to arithmetic overflows. If an overflow occurs during a line search, you can use the INSTEP= option to reduce the length of the first trial step during the first five iterations, or you can use the DAMPSTEP or MAXSTEP option to restrict the step length of the initial $\alpha$ in subsequent iterations. If an arithmetic overflow occurs in the first iteration of the trust region or double dogleg algorithms, you can use the INSTEP= option to reduce the default trust region radius of the first iteration. You can also change the optimization technique or the line-search method.

Long Run Times

PROC NLMIXED can take a long time to run for problems with complex models, many parameters, or large input data sets. Although the optimization techniques used by PROC NLMIXED are some of the best ones available, they are not guaranteed to converge quickly for all problems. Ill-posed or misspecified models can cause the algorithms to use more extensive calculations designed to achieve convergence, and this can result in longer run times. So first make sure that your model is specified correctly, that your parameters are scaled to be of the same order of magnitude, and that your data reasonably match the model you are contemplating.

If you are using the default adaptive Gaussian quadrature algorithm and no iteration history is printing at all, then PROC NLMIXED may be bogged down trying to determine the number of quadrature points at the first set of starting values. Specifying the QPOINTS= option will bypass this stage and proceed directly to iterations; however, be aware that the likelihood approximation may not be accurate if there are too few quadrature points.
PROC NLMIXED may also have difficulty determining the number of quadrature points if the initial starting values are far from the optimum values. To obtain more accurate starting values for the model parameters, one easy method is to fit a model with no RANDOM statement. You can then use these estimates as starting values, although you will still need to specify values for the random-effects distribution. For normal-normal models, another strategy is to use METHOD=FIRO. If you can obtain estimates using this approximate method, then they can be used as starting values for more accurate likelihood approximations.

If you are running PROC NLMIXED multiple times, you will probably want to include a statement like the following in your program:

```sas
ods output ParameterEstimates=pe;
```

This statement creates a SAS data set named PE upon completion of the run. In your next invocation of PROC NLMIXED, you can then specify

```sas
parms / data=pe;
```

to read in the previous estimates as starting values.

To speed general computations, you should check over your programming statements to minimize the number of floating point operations. Using auxiliary variables and factoring amenable expressions can be useful changes in this regard.

### Problems Evaluating Code for Objective Function

The starting point $\theta^{(0)}$ must be a point for which the programming statements can be evaluated. However, during optimization, the optimizer may iterate to a point $\theta^{(k)}$ where the objective function or its derivatives cannot be evaluated. In some cases, the specification of boundary for parameters can avoid such situations. In many other cases, you can indicate that the point $\theta^{(0)}$ is a bad point simply by returning an extremely large value for the objective function. In these cases, the optimization algorithm reduces the step length and stays closer to the point that has been evaluated successfully in the former iteration.

### No Convergence

There are a number of things to try if the optimizer fails to converge.

- Change the initial values by using a grid search specification to obtain a set of good feasible starting values.
- Change or modify the update technique or the line-search algorithm.

This method applies only to TECH=QUANEW and TECH=CONGRA. For example, if you use the default update formula and the default line-search algorithm, you can

- change the update formula with the UPDATE= option
– change the line-search algorithm with the LIS= option
– specify a more precise line search with the LSPRECISION= option, if you use LIS=2 or LIS=3

• Change the optimization technique.
  For example, if you use the default option, TECH=QUANEW, you can try one of the second-derivative methods if your problem is small or the conjugate gradient method if it is large.

• Adjust finite difference derivatives.
  The forward difference derivatives specified with the FD[=] or FDHESSIAN[=] option may not be precise enough to satisfy strong gradient termination criteria. You may need to specify the more expensive central difference formulas. The finite difference intervals may be too small or too big, and the finite difference derivatives may be erroneous.

• Double-check the data entry and program specification.

**Convergence to Stationary Point**

The gradient at a stationary point is the null vector, which always leads to a zero search direction. This point satisfies the first-order termination criterion. Search directions that are based on the gradient are zero, so the algorithm terminates. There are two ways to avoid this situation:

• Use the PARMS statement to specify a grid of feasible initial points.
• Use the OPTCHECK[=r] option to avoid terminating at the stationary point.

The signs of the eigenvalues of the (reduced) Hessian matrix contain information regarding a stationary point.

• If all of the eigenvalues are positive, the Hessian matrix is positive definite, and the point is a minimum point.
• If some of the eigenvalues are positive and all remaining eigenvalues are zero, the Hessian matrix is positive semidefinite, and the point is a minimum or saddle point.
• If all of the eigenvalues are negative, the Hessian matrix is negative definite, and the point is a maximum point.
• If some of the eigenvalues are negative and all of the remaining eigenvalues are zero, the Hessian matrix is negative semidefinite, and the point is a maximum or saddle point.
• If all of the eigenvalues are zero, the point can be a minimum, maximum, or saddle point.
**Precision of Solution**

In some applications, PROC NLMIXED may result in parameter values that are not precise enough. Usually, this means that the procedure terminated at a point too far from the optimal point. The termination criteria define the size of the termination region around the optimal point. Any point inside this region can be accepted for terminating the optimization process. The default values of the termination criteria are set to satisfy a reasonable compromise between the computational effort (computer time) and the precision of the computed estimates for the most common applications. However, there are a number of circumstances in which the default values of the termination criteria specify a region that is either too large or too small.

If the termination region is too large, then it can contain points with low precision. In such cases, you should determine which termination criterion stopped the optimization process. In many applications, you can obtain a solution with higher precision simply by using the old parameter estimates as starting values in a subsequent run in which you specify a smaller value for the termination criterion that was satisfied at the former run.

If the termination region is too small, the optimization process may take longer to find a point inside such a region, or it may not even find such a point due to rounding errors in function values and derivatives. This can easily happen in applications in which finite difference approximations of derivatives are used and the GCONV and ABSGCONV termination criteria are too small to respect rounding errors in the gradient values.

**Covariance Matrix**

The estimated covariance matrix of the parameter estimates is computed as the inverse Hessian matrix, and for unconstrained problems it should be positive definite. If the final parameter estimates are subjected to \( n_{\text{act}} > 0 \) active linear inequality constraints, the formulas of the covariance matrices are modified similar to Gallant (1987) and Cramer (1986, p. 38) and additionally generalized for applications with singular matrices.

There are several steps available that enable you to tune the rank calculations of the covariance matrix.

1. You can use the ASINGULAR=, MSINGULAR=, and VSINGULAR= options to set three singularity criteria for the inversion of the Hessian matrix \( H \). The singularity criterion used for the inversion is

   \[
   |d_{j,j}| \leq \max(\text{ASING}, \text{VSING} \times |H_{j,j}|, \text{MSING} \times \max(|H_{1,1}|, \ldots, |H_{n,n}|))
   \]

   where \( d_{j,j} \) is the diagonal pivot of the matrix \( H \), and ASING, VSING, and MSING are the specified values of the ASINGULAR=, VSINGULAR=, and MSINGULAR= options. The default values are
   
   - **ASING**: the square root of the smallest positive double precision value
   - **MSING**: \( 1E - 12 \) if you do not specify the SINGHESS= option and \( \max(10\epsilon, 1E-4\times\text{SINGHESS}) \) otherwise, where \( \epsilon \) is the machine precision
• VSING: 1E − 8 if you do not specify the SINGHESS= option and the value of SINGHESS otherwise

Note that, in many cases, a normalized matrix $D^{-1}AD^{-1}$ is decomposed, and the singularity criteria are modified correspondingly.

2. If the matrix $H$ is found to be singular in the first step, a generalized inverse is computed. Depending on the G4= option, either a generalized inverse satisfying all four Moore-Penrose conditions is computed or a generalized inverse satisfying only two Moore-Penrose conditions is computed. If the number of parameters $n$ of the application is less than or equal to G4=i, a G4 inverse is computed; otherwise, only a G2 inverse is computed. The G4 inverse is computed by the (computationally very expensive but numerically stable) eigenvalue decomposition, and the G2 inverse is computed by Gauss transformation. The G4 inverse is computed using the eigenvalue decomposition $A = ZΛZ^T$, where $Z$ is the orthogonal matrix of eigenvectors and $Λ$ is the diagonal matrix of eigenvalues, $Λ = diag(λ_1, ..., λ_n)$. The G4 inverse of $H$ is set to

$$A^- = ZΛ^-Z^T$$

where the diagonal matrix $Λ^- = diag(λ^-_1, ..., λ^-_n)$ is defined using the COVSING= option.

$$λ^-_i = \begin{cases} 
1/λ_i & \text{if } |λ_i| > \text{COVSING} \\
0 & \text{if } |λ_i| \leq \text{COVSING} 
\end{cases}$$

If you do not specify the COVSING= option, the $nr$ smallest eigenvalues are set to zero, where $nr$ is the number of rank deficiencies found in the first step.

For optimization techniques that do not use second-order derivatives, the covariance matrix is computed using finite difference approximations of the derivatives.

**Prediction**

The nonlinear mixed model is a useful tool for statistical prediction. Assuming a prediction is to be made regarding the $i$th subject, suppose that $f(θ, u_i)$ is a differentiable function predicting some quantity of interest. Recall that $θ$ denotes the vector of unknown parameters and $u_i$ denotes the vector of random effects for the $i$th subject. A natural point prediction is $f(\hat{θ}, \hat{u}_i)$, where $\hat{θ}$ is the maximum likelihood estimate of $θ$ and $\hat{u}_i$ is the empirical Bayes estimate of $u_i$ described previously in “Integral Approximations.”

An approximate prediction variance matrix for $(\hat{θ}, \hat{u}_i)$ is

$$P = \begin{bmatrix}
\hat{H}^{-1} & \hat{H}^{-1} \left(\frac{∂\hat{u}_i}{∂θ}\right)^T \\
\left(\frac{∂\hat{u}_i}{∂θ}\right)^T \hat{H}^{-1} & \hat{Γ}^{-1} + \left(\frac{∂\hat{u}_i}{∂θ}\right) \hat{H}^{-1} \left(\frac{∂\hat{u}_i}{∂θ}\right)^T
\end{bmatrix}$$

where $\hat{H}$ is the approximate Hessian matrix from the optimization for $\hat{θ}$, $\hat{Γ}$ is the approximate Hessian matrix from the optimization for $\hat{u}_i$, and $(∂\hat{u}_i/∂θ)$ is the derivative
of $\hat{u}_i$ with respect to $\theta$, evaluated at $(\hat{\theta}, \hat{u}_i)$. The approximate variance matrix for $\hat{\theta}$ is the standard one discussed in the previous section, and that for $\hat{u}_i$ is an approximation to the conditional mean squared error of prediction described by Booth and Hobert (1998).

The prediction variance for a general scalar function $f(\theta, u_i)$ is defined as the expected squared difference $E[(f(\hat{\theta}, \hat{u}_i) - f(\theta, u_i))^2]$. PROC NLMIXED computes an approximation to it as follows. The derivative of $f(\theta, u_i)$ is computed with respect to each element of $(\theta, u_i)$ and evaluated at $(\hat{\theta}, \hat{u}_i)$. If $a_i$ is the resulting vector, then the approximate prediction variance is $a_i^T P a_i$. This approximation is known as the delta method (Billingsley, 1986; Cox, 1998).

### Computational Resources

Since nonlinear optimization is an iterative process that depends on many factors, it is difficult to estimate how much computer time is necessary to find an optimal solution satisfying one of the termination criteria. You can use the MAXTIME=, MAXITER=, and MAXFU= options to restrict the amount of CPU time, the number of iterations, and the number of function calls in a single run of PROC NLMIXED.

In each iteration $k$, the NRRIDG technique uses a symmetric Householder transformation to decompose the $n \times n$ Hessian matrix $H$

$$H = V^T V, \quad V: \text{orthogonal}, \quad T: \text{tridiagonal}$$

to compute the (Newton) search direction $s$

$$s^{(k)} = -[H^{(k)}]^{-1} g^{(k)} \quad k = 1, 2, 3, \ldots$$

The TRUREG and NEWRAP techniques use the Cholesky decomposition to solve the same linear system while computing the search direction. The QUANEW, DBLDOG, CONGRA, and NMSIMP techniques do not need to invert or decompose a Hessian matrix; thus, they require less computational resources than the other techniques.

The larger the problem, the more time is needed to compute function values and derivatives. Therefore, you may want to compare optimization techniques by counting and comparing the respective numbers of function, gradient, and Hessian evaluations.

Finite difference approximations of the derivatives are expensive because they require additional function or gradient calls:

- forward difference formulas
  - For first-order derivatives, $n$ additional function calls are required.
  - For second-order derivatives based on function calls only, for a dense Hessian, $n + n^2/2$ additional function calls are required.
  - For second-order derivatives based on gradient calls, $n$ additional gradient calls are required.
central difference formulas
  – For first-order derivatives, \(2n\) additional function calls are required.
  – For second-order derivatives based on function calls only, for a dense Hessian, \(2n + 2n^2\) additional function calls are required.
  – For second-order derivatives based on gradient calls, \(2n\) additional gradient calls are required.

Many applications need considerably more time for computing second-order derivatives (Hessian matrix) than for computing first-order derivatives (gradient). In such cases, a dual quasi-Newton technique is recommended, which does not require second-order derivatives.

### Displayed Output

This section describes the displayed output from PROC NLMIXED. See the section “ODS Table Names” on page 3107 for details about how this output interfaces with the Output Delivery System.

### Specifications

The NLMIXED procedure first displays the “Specifications” table, listing basic information about the nonlinear mixed model that you have specified. It includes the principal variables and estimation methods.

### Dimensions

The “Dimensions” table lists counts of important quantities in your nonlinear mixed model, including the number of observations, subjects, parameters, and quadrature points.

### Parameters

The “Parameters” table displays the information you provided with the PARMS statement and the value of the negative log likelihood function evaluated at the starting values.

### Starting Gradient and Hessian

The START option in the PROC NLMIXED statement displays the gradient of the negative log likelihood function at the starting values of the parameters. If you also specify the HESS option, then the starting Hessian is displayed as well.

### Iterations

The iteration history consists of one line of output for each iteration in the optimization process. The iteration history is displayed by default because it is important that you check for possible convergence problems. The default iteration history includes the following variables:

- Iter, the iteration number
- Calls, the number of function calls
• NegLogLike, the value of the objective function
• Diff, the difference between adjacent function values
• MaxGrad, the maximum of the absolute (projected) gradient components (except NMSIMP)
• Slope, the slope $g^T s$ of the search direction $s$ at the current parameter iterate $\theta_{(k)}$ (QUANEW only)
• Rho, the ratio between the achieved and predicted value of Diff (NRRIDG only)
• Radius, the radius of the trust region (TRUREG only)
• StdDev, the standard deviation of the simplex values (NMSIMP only)
• Delta, the vertex length of the simplex (NMSIMP only)
• Size, the size of the simplex (NMSIMP only)

For the QUANEW method, the value of Slope should be significantly negative. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently. If this difficulty is encountered, an asterisk (*) appears after the iteration number. If there is a tilde (~) after the iteration number, the BFGS update is skipped, and very high values of the Lagrange function are produced. A backslash (\) after the iteration number indicates that Powell’s correction for the BFGS update is used.

For methods using second derivatives, an asterisk (*) after the iteration number means that the computed Hessian approximation was singular and had to be ridged with a positive value.

For the NMSIMP method, only one line is displayed for several internal iterations. This technique skips the output for some iterations because some of the termination tests (StdDev and Size) are rather time consuming compared to the simplex operations, and they are performed only every five simplex operations.

The ITDETAILS option in the PROC NLMIXED statement provides a more detailed iteration history. Besides listing the current values of the parameters and their gradients, the following values are provided in addition to the default output:

• Restart, the number of iteration restarts
• Active, the number of active constraints
• Lambda, the value of the Lagrange multiplier (TRUREG and DBLDOG only)
• Ridge, the ridge value (NRRIDG only)
• Alpha, the line-search step size (QUANEW only)

An apostrophe (‘) trailing the number of active constraints indicates that at least one of the active constraints was released from the active set due to a significant Lagrange multiplier.
Fitting Information

The “Fitting Information” table lists the final minimized value of $-2$ times the log likelihood as well as the information criteria of Akaike (AIC) and Schwarz (BIC), as well as a finite-sample corrected version of AIC (AICC). The criteria are computed as follows:

$$
AIC = 2f(\hat{\theta}) + 2p \\
AICC = 2f(\hat{\theta}) + \frac{2pn}{(n - p - 1)} \\
BIC = 2f(\hat{\theta}) + p\log(s)
$$

where $f()$ is the negative of the marginal log likelihood function, $\hat{\theta}$ is the vector of parameter estimates, $p$ is the number of parameters, $n$ is the number of observations, and $s$ is the number of subjects. Refer to Hurvich and Tsai (1989) and Burnham and Anderson (1998) for additional details.

Parameter Estimates

The “Parameter Estimates” table lists the estimates of the parameter values after successful convergence of the optimization problem or the final values of the parameters under nonconvergence. If the problem did converge, standard errors are computed from the final Hessian matrix. The ratio of the estimate with its standard error produces a $t$ value, with approximate degrees of freedom computed as the number of subjects minus the number of random effects. A $p$-value and confidence limits based on this $t$ distribution are also provided. Finally, the gradient of the negative log likelihood function is displayed for each parameter, and you should verify that they each are sufficiently small for non-constrained parameters.

Covariance and Correlation Matrices

Following standard maximum likelihood theory (for example, Serfling 1980), the asymptotic variance-covariance matrix of the parameter estimates equals the inverse of the Hessian matrix. You can display this matrix with the COV option in the PROC NLMIXED statement. The corresponding correlation form is available with the CORR option.

Additional Estimates

The “Additional Estimates” table displays the results of all ESTIMATE statements that you specify, with the same columns as the “Parameter Estimates” table. The ECOV and ECORR options in the PROC NLMIXED statement produce tables displaying the approximate covariance and correlation matrices of the additional estimates. They are computed using the delta method (Billingsley 1986; Cox 1998). The EDER option in the PROC NLMIXED statement produces a table displaying the derivatives of the additional estimates with respect to the model parameters evaluated at their final estimated values.
ODS Table Names

PROC NL MIXED assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 51.2. ODS Tables Produced in PROC NL MIXED

Examples

Example 51.1. One-Compartment Model with Pharmacokinetic Data

A popular application of nonlinear mixed models is in the field of pharmacokinetics, which studies how a drug disperses through a living individual. This example considers the theophylline data from Pinheiro and Bates (1995). Serum concentrations of the drug theophylline are measured in 12 subjects over a 25-hour period after oral administration. The data are as follows.

data theoph;
  input subject time conc dose wt;
  datalines;
  1  0.00  0.74  4.02  79.6
  1  0.25  2.84  4.02  79.6

</table>
Pinheiro and Bates (1995) consider the following first-order compartment model for these data:

\[ C_{it} = \frac{D k_e_i k_{a_i}}{C_l_i (k_{a_i} - k_{e_i})} \left[ \exp(-k_{e_i} t) - \exp(-k_{a_i} t) \right] + e_{it} \]

where \( C_{it} \) is the observed concentration of the \( i \)th subject at time \( t \), \( D \) is the dose of theophylline, \( k_{e_i} \) is the elimination rate constant for subject \( i \), \( k_{a_i} \) is the absorption rate constant for subject \( i \), \( C_l_i \) is the clearance for subject \( i \), and \( e_{it} \) are normal errors.

To allow for random variability between subjects, they assume

\[
\begin{align*}
C_{l_i} &= \exp(\beta_1 + b_{11}) \\
k_{a_i} &= \exp(\beta_2 + b_{12}) \\
k_{e_i} &= \exp(\beta_3)
\end{align*}
\]

where the \( \beta \)s denote fixed-effects parameters and the \( b \)s denote random-effects parameters with an unknown covariance matrix.

The PROC NLMIXED statements to fit this model are as follows.

```sas
proc nlmixed data=theoph;
parms beta1=-3.22 beta2=0.47 beta3=-2.45
          s2b1=0.03 cb12=0 s2b2=0.4 s2=0.5;
        cl = exp(beta1 + b1);      
        ka = exp(beta2 + b2);      
        ke = exp(beta3);           
        pred = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
model conc ~ normal(pred,s2);
random b1 b2 ~ normal([0,0],[s2b1,cb12,s2b2]) subject=subject;
run;
```

The PARMS statement specifies starting values for the three \( \beta \)s and four variance-covariance parameters. The clearance and rate constants are defined using SAS programming statements, and the conditional model for the data is defined to be normal.
with mean PRED and variance S2. The two random effects are B1 and B2, and their joint distribution is defined in the RANDOM statement. Brackets are used in defining their mean vector (two zeroes) and the lower triangle of their variance-covariance matrix (a general $2 \times 2$ matrix). The SUBJECT= variable is SUBJECT.

The results from this analysis are as follows.

The “Specifications” table lists the set up of the model.

The “Dimensions” table indicates that there are 132 observations, 12 subjects, and 7 parameters. PROC NLMIXED selects 5 quadrature points for each random effect, producing a total grid of 25 points over which quadrature is performed.
The "Parameters" table lists the 7 parameters, their starting values, and the initial evaluation of the negative log likelihood using adaptive Gaussian quadrature.

The “Parameter Estimates” table contains the maximum likelihood estimates of the parameters. Both S2B1 and S2B2 are marginally significant, indicating between-subject variability in the clearances and absorption rate constants, respectively. There does not appear to be a significant covariance between them, as seen by the estimate of CB12.

The estimates of $\beta_1$, $\beta_2$, and $\beta_3$ are close to the adaptive quadrature estimates listed in Table 3 of Pinheiro and Bates (1995). However, Pinheiro and Bates use a Cholesky-root parameterization for the random-effects variance matrix and a logarithmic parameterization for the residual variance. The PROC NLMIXED statements using their parameterization are as follows, and results are similar.

```sas
proc nlmixed data=theoph;
   parms ll1=-1.5 l2=0 ll3=-0.1 beta1=-3 beta2=0.5 beta3=-2.5
        ls2=-0.7;
   s2 = exp(ls2);
   l1 = exp(ll1);
   l3 = exp(ll3);
   s2b1 = l1*l1*s2;
   cb12 = l2*l1*s2;
   s2b2 = (l2*l2 + l3*l3)*s2;
   cl = exp(beta1 + b1);
   ka = exp(beta2 + b2);
   ke = exp(beta3);
   pred = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
   model conc ~ normal(pred,s2);
   random b1 b2 ~ normal([0,0],[s2b1,cb12,s2b2]) subject=subject;
run;
```
Example 51.2. Probit-Normal Model with Binomial Data

For this example, consider the data from Weil (1970), also studied by Williams (1975), Ochi and Prentice (1984), and McCulloch (1994). In this experiment 16 pregnant rats receive a control diet and 16 receive a chemically treated diet, and the litter size for each rat is recorded after 4 and 21 days. The SAS data set is as follows.

data rats;
  input trt$ m x;
  if (trt='c') then do;
    x1 = 1;
    x2 = 0;
  end;
  else do;
    x1 = 0;
    x2 = 1;
  end;
  litter = _n_;  
datalines;
  c 13 13
  c 12 12
  c 9 9
  c 9 9
  c 8 8
  c 8 8
  c 13 12
  c 12 11
  c 10 9
  c 10 9
  c 9 8
  c 13 11
  c 5 4
  c 7 5
  c 10 7
  c 10 7
  t 12 12
  t 11 11
  t 10 10
  t 9 9
  t 11 10
  t 10 9
  t 10 9
  t 9 8
  t 9 8
  t 5 4
  t 9 7
  t 7 4
  t 10 5
  t 6 3
  t 10 3
  t 7 0
run;
Here, \( M \) represents the size of the litter after 4 days, and \( X \) represents the size of the litter after 21 days. Also, indicator variables \( X_1 \) and \( X_2 \) are constructed for the two treatment levels.

Following McCulloch (1994), assume a latent survival model of the form

\[
y_{ijk} = t_i + \alpha_{ij} + e_{ijk}
\]

where \( i \) indexes treatment, \( j \) indexes litter, and \( k \) indexes newborn rats within a litter. The \( t_i \) represent treatment means, the \( \alpha_{ij} \) represent random litter effects assumed to be iid \( N(0, \sigma_i^2) \), and the \( e_{ijk} \) represent iid residual errors, all on the latent scale.

Instead of observing the survival times \( y_{ijk} \), assume that only the binary variable indicating whether \( y_{ijk} \) exceeds 0 is observed. If \( x_{ij} \) denotes the sum of these binary variables for the \( i \)th treatment and the \( j \)th litter, then the preceding assumptions lead to the following generalized linear mixed model:

\[
x_{ij} | \alpha_{ij} \sim \text{Binomial}(m_{ij}, p_{ij})
\]

where \( m_{ij} \) is the size of each litter after 4 days and

\[
p_{ij} = \Phi(t_i + \alpha_{ij})
\]

The PROC NLMIXED statements to fit this model are as follows.

```sas
proc nlmixed data=rats;
  parms t1=1 t2=1 s1=.05 s2=1;
  eta = x1*t1 + x2*t2 + alpha;
  p = probnorm(eta);
  model x ~ binomial(m,p);
  random alpha ~ normal(0,x1*s1*s1+x2*s2*s2) subject=litter;
  estimate 'gamma2' t2/sqrt(1+s2*s2);
  predict p out=p;
run;
```

As in the previous example, the PROC NLMIXED statement invokes the procedure and the PARMS statement defines the parameters. The parameters for this example are the two treatment means, \( T_1 \) and \( T_2 \), and the two random-effect standard deviations, \( S_1 \) and \( S_2 \).

The indicator variables \( X_1 \) and \( X_2 \) are used in the program to assign the proper mean to each observation in the input data set as well as the proper variance to the random effects. Note that programming expressions are permitted inside the distributional specifications, as illustrated by the random-effects variance specified here.

The ESTIMATE statement requests an estimate of \( \gamma_2 = t_2/\sqrt{1 + s_2^2} \), which is a location-scale parameter from Ochi and Prentice (1984).

The PREDICT statement constructs predictions for each observation in the input data set. For this example, predictions of \( P \) and approximate standard errors of prediction are output to a SAS data set named \( P \). These predictions are functions of the parameter estimates and the empirical Bayes estimates of the random effects \( \alpha_i \).
The output for this model is as follows.

The “Parameter Estimates” table indicates significance of all of the parameters except S1.
The "Additional Estimates" table displays results from the ESTIMATE statement. The estimate of $\gamma_2$ equals 0.66, agreeing with that obtained by McCulloch (1994). The standard error 0.22 is computed using the delta method (Billingsley 1986; Cox, 1998).

Not shown is the P data set, which contains the original 32 observations and predictions of the $p_{ij}$.

**Example 51.3. Probit-Normal Model with Ordinal Data**

The data for this example are from Ezzet and Whitehead (1991), who describe a crossover experiment on two groups of patients using two different inhaler devices (A and B). Patients from group 1 used device A for one week and then device B for another week. Patients from group 2 used the devices in reverse order. The data entered as a SAS data set are as follows.

```sas
data inhaler;
  input clarity group time freq;
  gt = group*time;
  sub = floor(_n_+1)/2;
  datalines;
1 0 0 59
1 0 1 59
1 0 0 35
2 0 1 35
1 0 0 3
3 0 1 3
1 0 0 2
4 0 1 2
2 0 0 11
1 0 1 11
2 0 0 27
2 0 1 27
2 0 0 2
3 0 1 2
2 0 0 1
4 0 1 1
4 0 0 1
1 0 1 1
4 0 0 1
2 0 1 1
```
The response measurement, CLARITY, is the patients’ assessment on the clarity of the leaflet instructions for the devices. The CLARITY variable is on an ordinal scale, with 1=easy, 2=only clear after rereading, 3=not very clear, and 4=confusing. The GROUP variable indicates the treatment group and the TIME variable indicates the time of measurement. The FREQ variable indicates the number of patients with exactly the same responses. A variable GT is created to indicate a group by time interaction, and a variable SUB is created to indicate patients.

As in the previous example and in Hedeker and Gibbons (1994), assume an underlying latent continuous variable, here with the form

\[ y_{ij} = \beta_0 + \beta_1 g_i + \beta_2 t_j + \beta_3 g_i t_j + u_i + e_{ij} \]

where \( i \) indexes patient and \( j \) indexes the time period, \( g_i \) indicates groups, \( t_j \) indicates time, \( u_i \) is a patient-level normal random effect, and \( e_{ij} \) are iid normal errors. The \( \beta \)s are unknown coefficients to be estimated.

Instead of observing \( y_{ij} \), though, you observe only whether it falls in one of the four intervals: \((-\infty, 0), (0, I_1), (I_1, I_1 + I_2), \) or \((I_1 + I_2, \infty)\), where \( I_1 \) and \( I_2 \) are both positive. The resulting category is the value assigned to the CLARITY variable.

The following code sets up and fits this ordinal probit model:
The PROC statement specifies the input data set and requests correlations both for
the parameter estimates (CORR option) and the additional estimates specified with
ESTIMATE statements (ECORR option).

The parameters as defined in the PARMS statement are as follows. B0 (overall inter-
cept), B1 (group main effect), B2 (time main effect), B3 (group by time interaction),
SD (standard deviation of the random effect), I1 (increment between first and second
thresholds), and I2 (increment between second and third thresholds). The BOUNDS
statement restricts I1 and I2 to be positive.

The SAS programming statements begin by defining the linear predictor ETA, which
is a linear combination of the B parameters and a single random effect U. The next
statements define the ordinal likelihood according to the CLARITY variable, ETA,
and the increment variables. An error trap is included in case the likelihood becomes
too small.

A general log likelihood specification is used in the MODEL statement, and the
RANDOM statement defines the random effect U to have standard deviation SD and
subject variable SUB. The REPLICATE statement indicates that data for each subject
should be replicated according to the FREQ variable.

The ESTIMATE statements specify the second and third thresholds in terms of the
increment variables (the first threshold is assumed to equal zero for model identifi-
cability). Also computed is the intraclass correlation.

The output is as follows.

Example 51.4. Poisson-Normal Model with Count Data

This example uses the pump failure data of Gaver and O’Muircheartaigh (1987). The number of failures and the time of operation are recorded for 10 pumps. Each of the pumps is classified into one of two groups corresponding to either continuous or intermittent operation. The data are as follows.

```plaintext
data pump;
  input y t group;
pump = _n_;  
  logtstd = log(t) - 2.4564900;
datalines;
  5 94.320 1
  1 15.720 2
  5 62.880 1
  14 125.760 1
  3 5.240 2
  19 31.440 1
  1 1.048 2
  1 1.048 2
  4 2.096 2
  22 10.480 2
run;
```

Each row denotes data for a single pump, and the variable LOGTSTD contains the centered operation times.

Letting $y_{ij}$ denote the number of failures for the $j$th pump in the $i$th group, Draper (1996) considers the following hierarchical model for these data:

\[
\begin{align*}
y_{ij} | \lambda_{ij} & \sim \text{Poisson}(\lambda_{ij}) \\
\log \lambda_{ij} & = \alpha_i + \beta_i (\log t_{ij} - \log t) + e_{ij} \\
e_{ij} | \sigma^2 & \sim \text{Normal}(0, \sigma^2)
\end{align*}
\]

The model specifies different intercepts and slopes for each group, and the random effect is a mechanism for accounting for overdispersion.

The corresponding PROC NLMIXED statements are as follows.

```plaintext
proc nlmixed data=pump;
  parms logsig 0 beta1 1 beta2 1 alpha1 1 alpha2 1;
  if (group = 1) then eta = alpha1 + beta1*logtstd + e;
  else eta = alpha2 + beta2*logtstd + e;
  lambda = exp(eta);
  model y ~ poisson(lambda);
  random e ~ normal(0,exp(2*logsig)) subject=pump;
  estimate 'alpha1-alpha2' alpha1-alpha2;
  estimate 'beta1-beta2' beta1-beta2;
run;
```
Example 51.4. Poisson-Normal Model with Count Data

The output is as follows.

The “Parameter Estimates” and “Additional Estimates” tables list the maximum likelihood estimates for each of the parameters and two differences. The point estimates for the mean parameters agree fairly closely with the Bayesian posterior means reported by Draper (1996); however, the likelihood-based standard errors are roughly half the Bayesian posterior standard deviations. This is most likely due to the fact that the Bayesian standard deviations account for the uncertainty in estimating \( \sigma^2 \), whereas the likelihood values plug in its estimated value. This downward bias can be corrected somewhat by using the \( t_9 \) distribution shown here.
Example 51.5. Failure Time and Frailty Model

In this example an accelerated failure time model with proportional hazard is fitted with and without random effects. The data are from the “Getting Started” example of PROC LIFEREG, see Chapter 39, “The LIFEREG Procedure.” Thirty-eight patients are divided into two groups of equal size, and different pain relievers are assigned to each group. The outcome reported is the time in minutes until headache relief. The variable censor indicates whether relief was observed during the course of the observation period (censor = 0) or whether the observation is censored (censor = 1).

data headache;
  input minutes group censor @@;
  patient = _n_;
datalines;
11 1 0 12 1 0 19 1 0 19 1 0
19 1 0 19 1 0 21 1 0 20 1 0
21 1 0 21 1 0 20 1 0 21 1 0
20 1 0 21 1 1 25 1 0 27 1 0
30 1 0 21 1 1 24 1 1 14 2 0
16 2 0 16 2 0 21 2 0 21 2 0
23 2 0 23 2 0 23 2 0 23 2 0
25 2 1 23 2 0 24 2 0 24 2 0
26 2 1 32 2 1 30 2 1 30 2 0
32 2 1 20 2 1
;

In modeling survival data, censoring of observations must be taken into account carefully. In this example, only right censoring occurs. If g(t, β), h(t, β), and G(t, β) denote the density of failure, hazard function, and survival distribution function at time t, respectively, the log-likelihood can be written as

\[
l(\beta; t) = \sum_{i \in U_u} \log f(t_i, \beta) + \sum_{i \in U_c} \log G(t_i, \beta) \\
= \sum_{i \in U_u} \log h(t_i, \beta) + \sum_{i=1}^{n} \log G(t_i, \beta)
\]

Refer to Cox and Oakes (1984, ch. 3). In these expressions \( U_u \) is the set of uncensored observations, \( U_c \) is the set of censored observations, and \( n \) denotes the total sample size.

The proportional hazards specification expresses the hazard in terms of a baseline hazard, multiplied by a constant. In this example the hazard is that of a Weibull model and is parameterized as \( h(t, \beta) = \gamma \alpha (\alpha t)^{\gamma-1} \) and \( \alpha = \exp\{-x^t/\beta\} \).

The linear predictor is set equal to the intercept in the reference group (group = 2); this defines the baseline hazard. The corresponding distribution of survival past time \( t \) is \( G(t, \beta) = \exp\{-(\alpha t)^\gamma\} \). Refer to Cox and Oakes (1984, Table 2.1) and the
section “Supported Distributions” in Chapter 39, “The LIFEREG Procedure,” for this and other survival distribution models and various parameterizations.

The following NLMIXED statements fit this accelerated failure time model and estimate the cumulative distribution function of time to headache relief.

```plaintext
proc nlmixed data=headache;
  bounds gamma > 0;
  linp = b0 - b1*(group-2);
  alpha = exp(-linp);
  G_t  = exp(-(alpha*minutes)**gamma);
  g    = gamma*alpha*((alpha*minutes)**(gamma-1))*G_t;
  ll   = (censor=0)*log(g) + (censor=1)*log(G_t);
  model minutes ~ general(ll);
  predict 1-G_t out=cdf;
run;
proc print data=cdf;
  var group censor patient minutes pred;
run;
```

**Output 51.5.1. Analysis Results for Failure Time Model**

The “Specifications” table shows that no integration is required, since the model does not contain random effects.
No starting values were given for the three parameters. The NLMIXED procedure assigns the default values in this case.

After 17 iterations and 34 evaluations of the objective function, the procedure converges.
The parameter estimates and their standard errors are identical to those obtained with the LIFEREG procedure and the statements

```plaintext
proc lifereg data=headache;
  class group;
  model minutes*censor(1) = group / dist=weibull;
run;
```

The $t$ statistic and confidence limits are based on 38 degrees of freedom. The LIFEREG procedure computes $z$-intervals for the parameter estimates.

For the two groups you obtain

\[ \hat{\alpha}(\text{group} = 1) = \exp\{-3.3091 + 0.1933\} = 0.04434 \]
\[ \hat{\alpha}(\text{group} = 2) = \exp\{-3.3091\} = 0.03655 \]

The probabilities of headache relief by $t$ minutes are estimated as

\[ 1 - G(t, \text{group} = 1) = 1 - \exp\{-0.04434 \times t\}^{4.7128} \]
\[ 1 - G(t, \text{group} = 2) = 1 - \exp\{-0.03655 \times t\}^{4.7128} \]

These probabilities, calculated at the observed times, are shown for the two groups in Output 51.5.2.
Output 51.5.2. Estimated Cumulative Distribution Function

</tbody>
</table>

Since the slope estimate is negative with p-value of 0.0185, you can infer that pain reliever 1 leads to overall significantly faster relief, but the estimated probabilities give no information about patient-to-patient variation within and between groups. For example, while pain reliever 1 provides faster relief overall, some patients in group 2 may respond more quickly than other patients in group 1. A frailty model enables you to accommodate and estimate patient-to-patient variation in health status by introducing random effects into a subject’s hazard function.

The following statements model the hazard for patient \( i \) in terms of \( \alpha_i = \exp\{-x_i'\beta - z_i\} \), where \( z_i \) is a (normal) random patient effect. Notice that the only difference from the previous NLMIXED statements are the RANDOM statement and the addition of \( Z \) in the linear predictor. The empirical Bayes estimates of the random effect (RANDOM statement), the parameter estimates (ODS OUTPUT statement), and the estimated cumulative distribution function (PREDICT statement) are saved to subsequently graph the patient-specific distribution functions.
ods output ParameterEstimates=est;
proc nlmixed data=headache;
   bounds gamma > 0;
   linp = b0 - b1*(group-2) + z;

NOTE: GCONV convergence criterion satisfied.

The procedure converges after 15 iterations. The achieved -2 log likelihood is only 1.2 less than that in the model without random effects. Compared to a chi-square distribution with one degree of freedom, the addition of the random effect appears not to improve the model significantly. Care must be exercised, however, in the interpretation of likelihood ratio tests when the value under the null hypothesis falls on the boundary of the parameter space (refer to, for example, Self and Liang 1987).
The NLMIXED Procedure

The estimate of the Weibull parameter has changed drastically from the model without random effects. The variance of the patient random effect is \( \exp\{-2 \times 1.9027\} = 0.02225 \). The next listing shows the empirical Bayes estimates of the random effects. These are the adjustments made to the linear predictor in order to obtain a patient’s survival distribution.
The predicted values and patient-specific survival distributions can be plotted with the SAS code that follows.

```sas
data cdf; set cdf; symbolid = int((patient-1)/19);
proc transpose data=est(keep=estimate) out=trest;
data trest; set trest; rename col1=gamma col2=b0 col3=b1;
data pred; merge eb(keep=estimate)
  headache(keep=patient group);
  if _n_ = 1 then merge trest(keep=gamma b0 b1);
do minutes=11 to 32;
  linp = b0 - b1*(group-2) + estimate;
  pred = 1-exp(- (exp(-linp)*minutes)**gamma);
symbolid = patient+1;
output;
end;
keep pred minutes symbolid;
run;
```
data pred; set cdf(keep=pred minutes symbolid) pred;
run;

axis1 label=(angle=90 rotate=0
‘Estimated Patient-specific CDF’)  
minor=none;
axis2 label=('Minutes to Headache Relief’)  
minor=none order=(10 to 35 by 5);

symbol1 value=dot c=black h=0.15in i=none r=1;
symbol2 value=circle c=black h=0.15in i=none r=1;
symbol3 value=none c=black l=1 i=join r=19;
symbol4 value=none c=black l=2 i=join r=19;
proc gplot data=pred;
   plot pred*minutes=symbolid / frame cframe=ligr
         nolegend vaxis=axis1 haxis=axis2;
run;

The separation of the distribution functions by groups is evident in Output 51.5.4. Most of the distributions of patients in the first group are to the left of the distributions in the second group. The separation is not complete, however. Several patients assigned the second pain reliever experience headache relief more quickly than patients assigned to the first group.

Chapter 52
The NPAR1WAY Procedure

Overview

The NPAR1WAY procedure performs nonparametric tests for location and scale differences across a one-way classification. PROC NPAR1WAY also provides a standard analysis of variance on the raw data and tests based on the empirical distribution function.

PROC NPAR1WAY performs tests for location and scale differences based on the following scores of a response variable: Wilcoxon, median, Van der Waerden, Savage, Siegel-Tukey, Ansari-Bradley, Klotz, and Mood scores. Additionally, PROC NPAR1WAY provides tests using the raw input data as scores. When the data are classified into two samples, tests are based on simple linear rank statistics. When the data are classified into more than two samples, tests are based on one-way ANOVA statistics. Both asymptotic and exact p-values are available for these tests.

PROC NPAR1WAY also provides empirical distribution function (EDF) statistics, which test whether the distribution of a variable is the same across different groups. These include the Kolmogorov-Smirnov test, the Cramer-von Mises test, and, when the data are classified into only two samples, the Kuiper test. Exact p-values are available for the two-sample Kolmogorov-Smirnov test.

Getting Started

This example illustrates how you can use PROC NPAR1WAY to perform a one-way nonparametric analysis. The data from Halverson and Sherwood (1932) consist of weight gain measurements for five different levels of gossypol additive. Gossypol is a substance contained in cottonseed shells, and these data were collected to study the effect of gossypol on animal nutrition.

The following DATA step statements create the SAS data set Gossypol:

```
data Gossypol;
  input Dose n;
  do i=1 to n;
    input Gain @@;
    output;
  end;
datalines;
0 16
  228 229 218 216 224 208 235 229 219 224 220 232 200 208 232
.04 11
  186 229 220 208 228 198 222 273 216 198 213
.07 12
  179 193 183 180 143 204 114 188 178 134 208 196
.10 17
  130 87 135 116 118 165 151 59 126 64 78 94 150 160 122 110 178
```
The data set Gossypol contains the variable Dose, which represents the amount of gossypol additive, and the variable Gain, which represents the weight gain.

Researchers are interested in whether there is a difference in weight gain among the different dose levels of gossypol. The following statements invoke the NPAR1WAY procedure to perform a nonparametric analysis of this problem:

```latex
proc npar1way data=Gossypol;
  class Dose;
  var Gain;
run;
```

The variable Dose is the CLASS variable, and the VAR statement specifies the variable Gain is the response variable. The CLASS statement is required, and you must name only one CLASS variable. You may name one or more analysis variables in the VAR statement. If you omit the VAR statement, PROC NPAR1WAY analyzes all numeric variables in the data set except for the CLASS variable, the FREQ variable, and the BY variables.

Since no analysis options are specified in the PROC NPAR1WAY statement, the ANOVA, WILCOXON, MEDIAN, VW, SAVAGE, and EDF options are invoked by default. The following tables show the results of these analyses.

The tables in Figure 52.1 are produced with the ANOVA option. For each level of the CLASS variable Dose, PROC NPAR1WAY displays the number of observations and the mean of the analysis variable Gain. PROC NPAR1WAY displays a standard analysis of variance on the raw data. This gives the same results as the GLM and ANOVA procedures. The p-value for the F test is <.0001, which indicates that Dose accounts for a significant portion of the variability in the dependent variable Gain.

*Figure 52.1. Analysis of Variance*
The WILCOXON option produces the output in Figure 52.2. PROC NPAR1WAY first provides a summary of the Wilcoxon scores for the analysis variable Gain by class level. For each level of the CLASS variable Dose, PROC NPAR1WAY displays the following information: number of observations, sum of the Wilcoxon scores, expected sum under the null hypothesis of no difference among class levels, standard deviation under the null hypothesis, and mean score.

Next PROC NPAR1WAY displays the one-way ANOVA statistic, which for Wilcoxon scores is known as the Kruskal-Wallis test. The statistic equals 52.6656, with four degrees of freedom, which is the number of class levels minus one. The $p$-value, or probability of a larger statistic under the null hypothesis, is $<.0001$. This leads to rejection of the null hypothesis that there is no difference in location for Gain among the levels of Dose. This $p$-value is asymptotic, computed from the asymptotic chi-square distribution of the test statistic. For certain data sets it may also be useful to compute the exact $p$-value; for example, for small data sets, or data sets that are sparse, skewed, or heavily tied. You can use the EXACT statement to request exact $p$-values for any of the location or scale tests available in PROC NPAR1WAY.

**Figure 52.2.** Wilcoxon Score Analysis

Figure 52.3 through Figure 52.5 display the analyses produced by the MEDIAN, VW, and SAVAGE options. For each score type, PROC NPAR1WAY provides a summary of scores and the one-way ANOVA statistic, as previously described for Wilcoxon scores. Other score types available in PROC NPAR1WAY are Siegel-Tukey, Ansari-Bradley, Klotz, and Mood, which are used to test for scale differences. Additionally, you can request the SCORES=DATA option, which uses the input data as scores. This option gives you the flexibility to construct any scores for your data with the DATA step and then analyze these scores with PROC NPAR1WAY.

**Figure 52.5.** Savage Score Analysis

**Figure 52.6.** Empirical Distribution Function Analysis
The tables in Figure 52.6 display the empirical distribution function statistics, comparing the distribution of Gain for the different levels of Dose. These tables are produced by the EDF option, and they include Kolmogorov-Smirnov statistics and Cramer-von Mises statistics.

In the preceding example, the CLASS variable Dose has five levels, and the analyses examine possible differences among these five levels, or samples. The following statements invoke the NPAR1WAY procedure to perform a nonparametric analysis of the two lowest levels of Dose:

```latex
proc npar1way data=Gossypol;
   where Dose <= .04;
   class Dose;
   var Gain;
run;
```

The following tables show the results of this two-sample analysis. The tables in Figure 52.7 are produced by the ANOVA option.

```latex

**Figure 52.8.** Wilcoxon Two-Sample Analysis

**Figure 52.8** displays the output produced by the WILCOXON option. PROC NPAR1WAY provides a summary of the Wilcoxon scores for the analysis variable Gain for each of the two class levels. Since there are only two levels, PROC NPAR1WAY displays the two-sample test, based on the simple linear rank statistic with Wilcoxon scores. The normal approximation includes a continuity correction. To remove this, you can specify the CORRECT=NO option. PROC NPAR1WAY also gives a t approximation for the Wilcoxon two-sample test. And as for the multisample analysis, PROC NPAR1WAY computes a one-way ANOVA statistic, which for Wilcoxon scores is known as the Kruskal-Wallis test. All these p-values show no difference in Gain for the two Dose levels at the .05 level of significance.

**Figure 52.9** through **Figure 52.11** display the two-sample analyses produced by the MEDIAN, VW, and SAVAGE options.

Figure 52.12. Two-Sample EDF Tests

The tables in Figure 52.12 display the empirical distribution function statistics, comparing the distribution of Gain for the two levels of Dose. The p-value for the Kolmogorov-Smirnov two-sample test is 0.6199, which indicates no rejection of the null hypothesis that the Gain distributions are identical for the two levels of Dose.
Syntax

The following statements are available in PROC NPAR1WAY:

```
PROC NPAR1WAY < options > ;
   BY variables ;
   CLASS variable ;
   EXACT statistic-options < / computation-options > ;
   FREQ variable ;
   OUTPUT < OUT=SAS-data-set > < options > ;
   VAR variables ;
```

Both the PROC NPAR1WAY statement and the CLASS statement are required for the NPAR1WAY procedure. The rest of this section gives detailed syntax information for the BY, CLASS, EXACT, FREQ, OUTPUT, and VAR statements in alphabetical order after the description of the PROC NPAR1WAY statement. Table 52.1 summarizes the basic function of each PROC NPAR1WAY statement.

Table 52.1. Summary of PROC NPAR1WAY Statements

<table>
<thead>
<tr>
<th>Statement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BY</td>
<td>provides separate analyses for each BY group</td>

<td>identifies a frequency variable</td>
</tr>
<tr>
<td>OUTPUT</td>
<td>requests an output data set</td>
</tr>
<tr>
<td>VAR</td>
<td>identifies analysis variables</td>
</tr>
</tbody>
</table>

PROC NPAR1WAY Statement

```
PROC NPAR1WAY < options > ;
```

The PROC NPAR1WAY statement invokes the procedure and optionally identifies the input data set or requests particular analyses. By default, the procedure uses the most recently created SAS data set and omits missing values from the analysis. If you do not specify any analysis options, PROC NPAR1WAY performs an analysis of variance (option ANOVA), tests for location differences (options WILCOXON, MEDIAN, SAVAGE, and VW), and performs empirical distribution function tests (option EDF).

The following table lists the options available with the PROC NPAR1WAY statement. Descriptions follow in alphabetical order.
You can specify the following options in the PROC NPAR1WAY statement:

**AB**
requests an analysis using Ansari-Bradley scores. See the section “Ansari-Bradley Scores” on page 3168 for more information.

**ANOVA**
requests a standard analysis of variance on the raw data.

**CORRECT=NO**
suppresses the continuity correction for the Wilcoxon two-sample test and the Siegel-Tukey two-sample test. See the section “Simple Linear Rank Tests for Two-Sample Data” on page 3163 for more information.

**D**
requests the one-sided Kolmogorov-Smirnov $D^+$ and $D^-$ statistics and their asymptotic $p$-values, in addition to the two-sided $D$ statistic produced by the EDF option for two-sample data. The D option invokes the EDF option. The statistics $D^+$ and $D^-$ are provided automatically if you request exact Kolmogorov-Smirnov statistics with the KS option in the EXACT statement for two-sample data. See the section “Tests Based on the Empirical Distribution Function” on page 3168 for details on Kolmogorov-Smirnov statistics.

**DATA=SAS-data-set**
names the SAS data set to be analyzed by PROC NPAR1WAY. If you omit the DATA= option, the procedure uses the most recently created SAS data set.
EDF requests statistics based on the empirical distribution function. These include the Kolmogorov-Smirnov and Cramer-von Mises tests and, if there are only two classification levels, the Kuiper test. See the section “Tests Based on the Empirical Distribution Function” on page 3168 for more information.

The EDF option produces the Kolmogorov-Smirnov $D$ statistic for two-sample data. You can also request the one-sided $D+$ and $D−$ statistics for two-sample data with the $D$ option.

KLOTZ requests an analysis using Klotz scores. See the section “Klotz Scores” on page 3168 for more information.

MEDIAN requests an analysis using median scores. When there are two classification levels, or two samples, this option produces the two-sample median test. When there are more than two samples, this option produces the multisample median test, which is also known as the Brown-Mood test. See the section “Median Scores” on page 3167 for more information.

MISSING treats missing values of the CLASS variable as a valid class level.

MOOD requests an analysis using Mood scores. See the section “Mood Scores” on page 3168 for more information.

NOPRINT suppresses the display of all output. You can use the NOPRINT option when you only want to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

SAVAGE requests an analysis using Savage scores. See the section “Savage Scores” on page 3167 for more information.

SCORES=DATA requests an analysis using input data as scores. This option gives you the flexibility to construct any scores for your data with the DATA step and then analyze these scores with PROC NPAR1WAY. See the section “Scores for Linear Rank and One-Way ANOVA Tests” on page 3166 for more information. Using the SCORES=DATA option for raw (unscored) two-sample data produces a permutation test known as Pitman’s test.

ST requests an analysis using Siegel-Tukey scores. See the section “Siegel-Tukey Scores” on page 3167 for more information.
requests an analysis using Van der Waerden scores. See the section “Van der Waerden Scores” on page 3167 for more information.

**WILCOXON**

requests an analysis using Wilcoxon scores. When there are two classification levels, or two samples, this option produces the Wilcoxon rank-sum test. For any number of classification levels, this option produces the Kruskal-Wallis test. See the section “Wilcoxon Scores” on page 3166 for more information.

**BY Statement**

```
BY variables;
```

You can specify a BY statement with PROC NPAR1WAY to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the NPAR1WAY procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

**CLASS Statement**

```
CLASS variable;
```

The CLASS statement, which is required, names one and only one classification variable. The variable can be character or numeric. The CLASS variable identifies groups (or samples) in the data, and PROC NPAR1WAY provides analyses to examine differences among these groups. There may be two or more groups in the data.
The EXACT statement requests exact tests for the specified statistics. Optionally, PROC NPAR1WAY computes Monte Carlo estimates of the exact p-values. The statistic-options specify the statistics for which to provide exact tests, and the computation-options specify options for the computation of exact statistics.

CAUTION: PROC NPAR1WAY computes exact tests with fast and efficient algorithms that are superior to direct enumeration. Exact tests are appropriate when a data set is small, sparse, skewed, or heavily tied. For some large problems, computation of exact tests may require a large amount of time and memory. Consider using asymptotic tests for such problems. Alternatively, when asymptotic methods may not be sufficient for such large problems, consider using Monte Carlo estimation of exact p-values. See the section “Computational Resources” on page 3173 for more information.

Statistic-Options

The statistic-options specify the statistics for which to provide exact tests.

Exact p-values are available for all nonparametric tests of location and scale differences produced by PROC NPAR1WAY. These include tests based on the following scores: Wilcoxon, median, Van der Waerden, Savage, Siegel-Tukey, Ansari-Bradley, Klotz, and Mood scores. Additionally, exact p-values are available for tests using the raw input data as scores. The procedure computes exact p-values when the data are classified into two levels (two-sample tests) and when the data are classified into more than two levels (multisample tests). Two-sample tests are based on simple linear rank statistics. Multisample tests are based on one-way ANOVA statistics. Exact p-values are also available for the two-sample Kolmogorov-Smirnov test. See the section “Exact Tests” on page 3171 for details.

Table 52.3 lists the available statistic-options and the exact tests computed. The option names are identical to the corresponding options in the PROC NPAR1WAY statement and the OUTPUT statement.

If you list no statistic-options in the EXACT statement, then PROC NPAR1WAY computes all the available exact p-values for those tests requested in the PROC NPAR1WAY statement.
Table 52.3. EXACT Statement Statistic-Options

<td>Van der Waerden Test</td>
</tr>
</tbody>
</table>

**Computation-Options**

The *computation-options* specify options for computation of exact statistics. You can specify the following *computation-options* in the EXACT statement:

**ALPHA=**\(\alpha\)

specifies the level of the confidence limits for Monte Carlo \(p\)-value estimates. The value of the ALPHA= option must be between 0 and 1, and the default is 0.01. A confidence level of \(\alpha\) produces \(100(1 - \alpha)\)% confidence limits. The default of ALPHA=0.01 produces 99% confidence limits for the Monte Carlo estimates. The ALPHA= option invokes the MC option.

**MAXTIME=**\(\text{value}\)

specifies the maximum clock time (in seconds) that PROC NPAR1WAY can use to compute an exact \(p\)-value. If the procedure does not complete the computation within the specified time, the computation terminates. The value of the MAXTIME= option must be a positive number. The MAXTIME= option is valid for Monte Carlo estimation of exact \(p\)-values, as well as for direct exact \(p\)-value computation. See the section “Computational Resources” on page 3173 for more information.

**MC**

requests Monte Carlo estimation of exact \(p\)-values, instead of direct exact \(p\)-value computation. Monte Carlo estimation can be useful for large problems that require a great amount of time and memory for exact computations but for which asymptotic approximations may not be sufficient. See the section “Monte Carlo Estimation” on page 3174 for more information.

The MC option is available for all the EXACT statement statistic-options. The ALPHA=, N=, and SEED= options also invoke the MC option.

**N=**\(n\)

specifies the number of samples for Monte Carlo estimation. The value of the N= option must be a positive integer, and the default is 10,000 samples. Larger values of \(n\) produce more precise estimates of exact \(p\)-values. Because larger values of \(n\) generate more samples, the computation time increases. The N= option invokes the MC option.
POINT requests exact point probabilities for the test statistics.

The POINT option is available for all the EXACT statement statistic-options. The POINT option is not available with the MC option.

SEED=number specifies the initial seed for random number generation for Monte Carlo estimation. The value of the SEED= option must be an integer. If you do not specify the SEED= option, or if the SEED= value is negative or zero, PROC NPARIWAY uses the time of day from the computer's clock to obtain the initial seed. The SEED= option invokes the MC option.

FREQ Statement

FREQ variable;

The FREQ statement names a numeric variable that provides a frequency for each observation in the DATA= data set. If you use a FREQ statement, PROC NPARIWAY assumes that an observation occurs n times, where n is the value of the FREQ variable for that observation. The sum of the FREQ variable values represents the total number of observations, and the analysis is based on this expanded number of observations.

If the value of the FREQ variable is missing or is less than one, PROC NPARIWAY does not use that observation in the analysis. If the value of the FREQ variable is not an integer, PROC NPARIWAY uses only the integer portion as the frequency of the observation.

OUTPUT Statement

OUTPUT < OUT=SAS-data-set > < options > ;

The OUTPUT statement creates a SAS data set containing statistics computed by PROC NPARIWAY. You specify which statistics to store in the output data set, using options identical to those used in the PROC NPARIWAY statement. The output data set contains one observation for each analysis variable named in the VAR statement. For more information on the contents of the output data set, see the section “Output Data Set” on page 3175.

Note that you can use the Output Delivery System (ODS) to create a SAS data set from any piece of PROC NPARIWAY output. For more information, see Table 52.6 on page 3184 and Chapter 14, “Using the Output Delivery System.”

You can specify the following options in the OUTPUT statement:

OUT=SAS-data-set names the output data set. If you omit the OUT= option, the data set is named DATAn, where n is the smallest integer that makes the name unique.

options specifies the statistics you want in the new data set. The options are identical to those used in the PROC NPARIWAY statement to request analyses. Table 52.4 shows the available options. When you specify one of these options in the OUTPUT statement,
the output data set contains statistics from that analysis. See the section “Output Data Set” on page 3175 for a list of the output data set variables corresponding to each option.

If you do not specify any statistics options in the OUTPUT statement, then the output data set includes statistics from all analyses specified in the PROC NPAR1WAY statement.

</tbody>
</table>

**VAR Statement**

```
VAR variables;
```

The VAR statement names the response or dependent variables to be analyzed. These variables must be numeric. If the VAR statement is omitted, the procedure analyzes all numeric variables in the data set except for the CLASS variable, the FREQ variable, and the BY variables.

**Details**

**Missing Values**

If an observation has a missing value for a response variable, PROC NPAR1WAY excludes that observation from the analysis.

By default, PROC NPAR1WAY excludes observations with missing values of the CLASS variable. If you specify the MISSING option, PROC NPAR1WAY treats missing values of the CLASS variable as a valid class level and includes these observations in the analysis.

PROC NPAR1WAY treats missing BY variable values like any other BY variable value. The missing values form a separate BY group. When a value of the FREQ variable is missing, PROC NPAR1WAY excludes the observation from the analysis.
Tied Values

_Tied values_ occur when two or more observations are equal, whether the observations occur in the same sample or in different samples. In theory, nonparametric tests were developed for continuous distributions where the probability of a tie is zero. In practice, however, ties often occur. PROC NPAR1WAY uses the same method to handle ties for all score types. The procedure computes the scores as if there were no ties, averages the scores for tied observations, and assigns this average score to each observation with the same value.

When there are tied values, PROC NPAR1WAY first sorts the observations in ascending order and assigns ranks as if there were no ties. Then the procedure computes the scores based on these ranks, using the formula for the specified score type. The procedure averages the scores for tied observations and assigns this average score to each of the tied observations. Thus, all equal data values have the same score value. PROC NPAR1WAY then computes the test statistic from these scores.

Note that the asymptotic tests may be less accurate when the distribution of the data is heavily tied. For such data, it may be appropriate to use the exact tests provided by PROC NPAR1WAY as described in the section “Exact Tests” on page 3171.

When computing empirical distribution function statistics for data with ties, PROC NPAR1WAY uses the formulas given in the section “Tests Based on the Empirical Distribution Function” on page 3168. No special handling of ties is necessary.

Note that PROC NPAR1WAY bases its computations on the internal numeric values of the analysis variables; the procedure does not format or round these values before analysis. When values differ in their internal representation, even slightly, PROC NPAR1WAY does not treat them as tied values. If this is a concern for your data, then round the analysis variables by an appropriate amount before invoking PROC NPAR1WAY. For information on the ROUND function, refer to the discussion in SAS Language Reference: Dictionary.

Statistical Computations

Simple Linear Rank Tests for Two-Sample Data

Statistics of the form

\[ S = \sum_{j=1}^{n} c_j a(R_j) \]

are called _simple linear rank statistics_, where

- \( R_j \) is the rank of the observation \( j \)
- \( a(R_j) \) is the score based on that rank
- \( c_j \) is an indicator variable denoting the class to which the \( j \)th observation belongs
- \( n \) is the total number of observations
For two-sample data (where the observations are classified into two levels), PROC NPAR1WAY calculates simple linear rank statistics for the scores that you specify. The section “Scores for Linear Rank and One-Way ANOVA Tests” on page 3166 describes the available scores, which you can use to test for differences in location and differences in scale.

To compute \( S \), PROC NPAR1WAY sums the scores of the observations in the smaller of the two samples. If both samples have the same number of observations, PROC NPAR1WAY sums those scores for the sample that appears first in the input data set.

For each score that you specify, PROC NPAR1WAY computes an asymptotic test of the null hypothesis of no difference between the two classification levels. Exact tests are also available for these two-sample linear rank statistics. PROC NPAR1WAY computes exact tests for each score type that you specify in the EXACT statement. See the section “Exact Tests” on page 3171 for details.

To compute an asymptotic test for a linear rank sum statistic, PROC NPAR1WAY uses a standardized test statistic \( z \), which has an asymptotic standard normal distribution under the null hypothesis. The standardized test statistic is computed as

\[
    z = \frac{S - E_0(S)}{\sqrt{Var_0(S)}}
\]

where \( E_0(S) \) is the expected value of \( S \) under the null hypothesis, and \( Var_0(S) \) is the variance under the null hypothesis. As shown in Randles and Wolfe (1979),

\[
    E_0(S) = \frac{n_1}{n} \sum_{j=1}^{n} a(R_j)
\]

where \( n_1 \) is the number of observations in the first (smaller) class level or sample, \( n_2 \) is the number of observations in the other class level, and

\[
    Var_0(S) = \frac{1}{(n-1)} \frac{n_1 n_2}{n} \left[ \sum_{j=1}^{n} (a(R_j) - \bar{a})^2 \right]
\]

where \( \bar{a} \) is the average score,

\[
    \bar{a} = \frac{1}{n} \sum_{j=1}^{n} a(R_j)
\]

PROC NPAR1WAY computes one-sided and two-sided asymptotic \( p \)-values for each two-sample linear rank test. When the test statistic \( z \) is greater than its null hypothesis expected value of zero, PROC NPAR1WAY computes the right-sided \( p \)-value, which is the probability of a larger value of the statistic occurring under the null hypothesis. When the test statistic is less than or equal to zero, PROC NPAR1WAY computes the
left-sided \( p \)-value, which is the probability of a smaller value of the statistic occurring under the null hypothesis. The one-sided \( p \)-value \( P_1 \) can be expressed as

\[
P_1 = \text{Prob} ( Z > z ) \quad \text{if } z > 0
\]

\[
P_1 = \text{Prob} ( Z < z ) \quad \text{if } z \leq 0
\]

where \( Z \) has a standard normal distribution. The two-sided \( p \)-value \( P_2 \) is computed as

\[
P_2 = \text{Prob} ( |Z| > |z| )
\]

For Wilcoxon scores and Siegel-Tukey scores, PROC NPAR1WAY incorporates a continuity correction when computing the standardized test statistic \( z \), unless you specify the \text{CORRECT=NO} \text{ option}. PROC NPAR1WAY applies the continuity correction by subtracting 0.5 from the numerator \( S - E_0(S) \) if it is greater than zero. If the numerator is less than zero, PROC NPAR1WAY adds 0.5. Some sources recommend a continuity correction for nonparametric tests that use a continuous distribution to approximate a discrete distribution. Refer to Sheskin (1997). If you specify \text{CORRECT=NO}, PROC NPAR1WAY does not use a continuity correction for any test.

### One-Way ANOVA Tests

PROC NPAR1WAY computes a one-way ANOVA test for each score type that you specify. Under the null hypothesis of no difference among class levels (or samples), this test statistic has an asymptotic chi-square distribution with \( r - 1 \) degrees of freedom, where \( r \) is the number of class levels. For Wilcoxon scores, this test is known as the Kruskal-Wallis test.

Exact one-way ANOVA tests are also available for multisample data (where the data are classified into more than two levels). For two-sample data, exact simple linear rank tests are available. PROC NPAR1WAY computes exact tests for each score type that you specify in the \text{EXACT} \text{ statement}. See the section “Exact Tests” on page 3171 for details on exact tests.

PROC NPAR1WAY computes the one-way ANOVA test statistic as

\[
C = \left( \frac{\sum_{i=1}^{r} (T_i - E_0(T_i))^2 / n_i}{S^2} \right)
\]

where \( T_i \) is the total of scores for the class level \( i \), \( E_0(T_i) \) is the expected total for level \( i \) under the null hypothesis of no difference among levels, \( n_i \) is the number of observations in level \( i \), and \( S^2 \) is the sample variance of the scores.

\[
T_i = \sum_{j=1}^{n} c_{ij} a(R_j)
\]
where $a(R_j)$ is the score for observation $j$, and $c_{ij}$ indicates whether observation $j$ is in level $i$.

$$E_0(T_i) = \frac{n_i}{n} \sum_{j=1}^{n} a(R_j)$$

$$S^2 = \frac{1}{(n - 1)} \left[ \sum_{j=1}^{n} (a(R_j) - \bar{a})^2 \right]$$

where $\bar{a}$ is the average score,

$$\bar{a} = \sum_{j=1}^{n} a(R_j) / n$$

**Scores for Linear Rank and One-Way ANOVA Tests**

For each score type that you specify, PROC NPAP1WAY computes a one-way ANOVA statistic and also a linear rank statistic for two-sample data. The following score types are used primarily to test for differences in location: Wilcoxon, median, Van der Waerden, and Savage. The following scores types are used to test for scale differences: Siegel-Tukey, Ansari-Bradley, Klotz, and Mood. This section gives formulas for the score types. For further information on the formulas and the applicability of each score, refer to Randles and Wolfe (1979), Gibbons and Chakraborti (1992), Conover (1999), and Hollander and Wolfe (1999).

In addition to the score types described in this section, you can specify the SCORES=DATA option to use the input data observations as scores. This enables you to produce a very wide variety of tests. You can construct any scores using the DATA step, and then PROC NPAP1WAY computes the corresponding linear rank and one-way ANOVA tests. You can also analyze the raw data with the SCORES=DATA option; for two-sample data, this permutation test is known as Pitman’s test.

**Wilcoxon Scores**

Wilcoxon scores are the ranks of the observations.

$$a(R_j) = R_j$$

Using Wilcoxon scores in the linear rank statistic for two-sample data produces the rank sum statistic of the Mann-Whitney-Wilcoxon test. Using Wilcoxon scores in the one-way ANOVA statistic produces the Kruskal-Wallis test. Wilcoxon scores are locally most powerful for location shifts of a logistic distribution.

When computing the asymptotic Wilcoxon two-sample test, PROC NPAP1WAY uses a continuity correction by default, as described in the section “Simple Linear Rank Tests for Two-Sample Data” on page 3163. If you specify CORRECT=NO in the PROC NPAP1WAY statement, the procedure does not use a continuity correction.
**Median Scores**

Median scores equal 1 for observations greater than the median, and 0 otherwise.

\[
a(R_j) = \begin{cases} 
1 & \text{if } R_j > \frac{n+1}{2} \\
0 & \text{if } R_j \leq \frac{n+1}{2}
\end{cases}
\]

Using median scores in the linear rank statistic for two-sample data produces the two-sample median test. The one-way ANOVA statistic with median scores is equivalent to the Brown-Mood test. Median scores are particularly powerful for distributions that are symmetric and heavy-tailed.

**Van der Waerden Scores**

Van der Waerden scores are the quantiles of a standard normal distribution. These scores are also known as *quantile normal scores*.

\[
a(R_j) = \Phi^{-1}\left( \frac{R_j}{n+1} \right)
\]

where \( \Phi \) is the cumulative distribution function of a standard normal distribution. These scores are powerful for normal distributions.

**Savage Scores**

Savage scores are expected values of order statistics from the exponential distribution, with 1 subtracted to center the scores around 0.

\[
a(R_j) = \sum_{i=1}^{R_j} \frac{1}{n - i + 1} - 1
\]

Savage scores are powerful for comparing scale differences in exponential distributions or location shifts in extreme value distributions (Hajek 1969, p. 83).

**Siegel-Tukey Scores**

Siegel-Tukey scores are computed as

\[
a(1) = 1, \quad a(n) = 2, \quad a(n - 1) = 3, \quad a(2) = 4, \\
a(3) = 5, \quad a(n - 2) = 6, \quad a(n - 3) = 7, \quad a(4) = 8, \ldots
\]

where the score values continue to increase in this pattern towards the middle ranks until all observations have been assigned a score.
Ansari-Bradley Scores

Ansari-Bradley scores are similar to Siegel-Tukey scores, but Ansari-Bradley assigns the same scores to corresponding extreme ranks. (Siegel Tukey scores are just a permutation of the ranks 1, 2, . . . , n.)

\[ a(1) = 1, \quad a(n) = 1, \]
\[ a(2) = 2, \quad a(n - 1) = 2, \ldots \]

Equivalently, Ansari-Bradley scores are defined as

\[ a(R_j) = \frac{n + 1}{2} - \left| R_j - \frac{n + 1}{2} \right| \]

Klotz Scores

Klotz scores are the squares of the Van der Waerden (or quantile normal) scores.

\[ a(R_j) = \left[ \Phi^{-1} \left( \frac{R_j}{n + 1} \right) \right]^2 \]

where \( \Phi \) is the cumulative distribution function of a standard normal distribution.

Mood Scores

Mood scores are computed as the square of the difference between each rank and the average rank.

\[ a(R_j) = \left[ R_j - \frac{n + 1}{2} \right]^2 \]

Tests Based on the Empirical Distribution Function

If you specify the EDF option, PROC NPAR1WAY computes tests based on the empirical distribution function. These include the Kolmogorov-Smirnov and Cramer-von Mises tests, and also the Kuiper test for two-sample data. This section gives formulas for these test statistics. For further information on the formulas and the interpretation of EDF statistics, refer to Hollander and Wolfe (1999) and Gibbons and Chakraborti (1992). For details on the k-sample analogues of the Kolmogorov-Smirnov and Cramer-von Mises statistics used by NPAR1WAY, refer to Kiefer (1959).

The empirical distribution function (EDF) of a sample \( \{x_j\}, j = 1, 2, \ldots, n \), is defined as the following function:

\[ F(x) = \frac{1}{n} \text{ (number of } x_j \leq x) = \frac{1}{n} \sum_{j=1}^{n} I(x_j \leq x) \]
where \( I(\cdot) \) is an indicator function. PROC NPAR1WAY uses the subsample of values within the \( i \)th class level to generate an EDF for the class, \( F_i \). The EDF for the overall sample, pooled over classes, can also be expressed as

\[
F = \frac{1}{n} \sum_i (n_i F_i)
\]

where \( n_i \) is the number of observations in the \( i \)th class level, and \( n \) is the total number of observations.

**Kolmogorov-Smirnov Test**

The Kolmogorov-Smirnov statistic measures the maximum deviation of the EDF within the classes from the pooled EDF. PROC NPAR1WAY computes the Kolmogorov-Smirnov statistic as

\[
KS = \max_j \sqrt{\frac{1}{n} \sum_i n_i \left( F_i(x_j) - F(x_j) \right)^2}
\]

where \( j = 1, 2, \ldots, n \)

The asymptotic Kolmogorov-Smirnov statistic is computed as

\[
KS_a = KS \times \sqrt{n}
\]

For each class level \( i \) and overall, PROC NPAR1WAY displays the value of \( F_i \) at the maximum deviation from \( F \) and the value \( (F_i - F) \sqrt{n_i} \) at the maximum deviation from \( F \). PROC NPAR1WAY also gives the observation where the maximum deviation occurs.

If there are only two class levels, PROC NPAR1WAY computes the two-sample Kolmogorov-Smirnov test statistic \( D \) as

\[
D = \max_j \left| F_1(x_j) - F_2(x_j) \right| \quad \text{where} \quad j = 1, 2, \ldots, n
\]

The \( p \)-value for this test is the probability that \( D \) is greater than the observed value \( d \) under the null hypothesis of no difference between class levels or samples. PROC NPAR1WAY computes the asymptotic \( p \)-value for \( D \) with the approximation

\[
\text{Prob} \left( D > d \right) = 1 - 2 \sum_{i=1}^{\infty} (-1)^{(i-1)} e^{-2i^2 z^2}
\]

where

\[
z = d \sqrt{\left( \frac{n_1 n_2}{n} \right)}
\]

The quality of this approximation has been studied by Hodges (1957).
If you specify the D option, or if you request exact Kolmogorov-Smirnov p-values with the KS option in the EXACT statement, PROC NPAR1WAY also computes the one-sided Kolmogorov-Smirnov statistics $D^+$ and $D^-$ for two-sample data.

\[
D^+ = \max_j (F_1(x_j) - F_2(x_j)) \quad \text{where } j = 1, 2, \ldots, n \\
D^- = \max_j (F_2(x_j) - F_1(x_j)) \quad \text{where } j = 1, 2, \ldots, n
\]

The asymptotic probability that $D^+$ is greater than the observed value $d^+$, under the null hypothesis of no difference between the two class levels, is computed as

\[
\text{Prob}(D^+ > d^+) = e^{-2z^2}, \quad \text{where } z = d^+ \sqrt{\left(\frac{n_1 n_2}{n}\right)}
\]

Similarly, the asymptotic probability that $D^-$ is greater than the observed value $d^-$ is computed as

\[
\text{Prob}(D^- > d^-) = e^{-2z^2}, \quad \text{where } z = d^- \sqrt{\left(\frac{n_1 n_2}{n}\right)}
\]

To request exact p-values for the Kolmogorov-Smirnov statistics, you can specify the KS option in the EXACT statement. See the section “Exact Tests” on page 3171 for more information.

**Cramer-von Mises Test**

The Cramer-von Mises statistic is defined as

\[
CM = \frac{1}{n^2} \sum_i \left( n_i \sum_{j=1}^p t_j (F_i(x_j) - F(x_j))^2 \right)
\]

where $t_j$ is the number of ties at the $j$th distinct value and $p$ is the number of distinct values. The asymptotic value is computed as

\[
CM_a = CM \times n
\]

PROC NPAR1WAY displays the contribution of each class level to the sum $CM_a$. 

---

**Chapter 52. The NPAR1WAY Procedure**
Kuiper Test

For data with two class levels, PROC NPAR1WAY computes the Kuiper statistic, its scaled value for the asymptotic distribution, and the asymptotic $p$-value. The Kuiper statistic is computed as

$$K = \max_j (F_1(x_j) - F_2(x_j)) - \min_j (F_1(x_j) - F_2(x_j)) \quad \text{where } j = 1, 2, \ldots, n$$

The asymptotic value is

$$K_a = K \sqrt{\frac{n_1 n_2}{n}}$$

PROC NPAR1WAY displays $\max_j |F_1(x_j) - F_2(x_j)|$ for each class level.

The $p$-value for the Kuiper test is the probability of observing a larger value of $K_a$ under the null hypothesis of no difference between the two classes. PROC NPAR1WAY computes this $p$-value according to Owen (1962), p. 441.

Exact Tests

PROC NPAR1WAY provides exact $p$-values for tests for location and scale differences based on the following scores: Wilcoxon, median, van der Waerden, Savage, Siegel-Tukey, Ansari-Bradley, Klotz, and Mood scores. Additionally, PROC NPAR1WAY provides exact $p$-values for tests using the raw data as scores. Exact tests are available for two-sample and multisample data. When the data are classified into two samples, tests are based on simple linear rank statistics. When the data are classified into more than two samples, tests are based on one-way ANOVA statistics.

Exact tests can be useful in situations where the asymptotic assumptions are not met and the asymptotic $p$-values are not close approximations for the true $p$-values. Standard asymptotic methods involve the assumption that the test statistic follows a particular distribution when the sample size is sufficiently large. When the sample size is not large, asymptotic results may not be valid, with the asymptotic $p$-values differing perhaps substantially from the exact $p$-values. Asymptotic results may also be unreliable when the distribution of the data is sparse, skewed, or heavily tied. Refer to Agresti (1996) and Bishop, Fienberg, and Holland (1975). Exact computations are based on the statistical theory of exact conditional inference for contingency tables, reviewed by Agresti (1992).

In addition to computation of exact $p$-values, PROC NPAR1WAY provides the option of estimating exact $p$-values by Monte Carlo simulation. This can be useful for problems that are so large that exact computations require a great amount of time and memory, but for which asymptotic approximations may not be sufficient.

The following sections summarize the exact computational algorithms, define the exact $p$-values that PROC NPAR1WAY computes, discuss the computational resource requirements, and describe the Monte Carlo estimation option.
Computational Algorithms

PROC NPAR1WAY computes exact \( p \)-values using the network algorithm developed by Mehta and Patel (1983). This algorithm provides a substantial advantage over direct enumeration, which can be very time consuming and feasible only for small problems. Refer to Agresti (1992) for a review of algorithms for computation of exact \( p \)-values, and refer to Mehta, Patel, and Tsiatis (1984) and Mehta, Patel, and Senchaudhuri (1991) for information on the performance of the network algorithm.

PROC NPAR1WAY constructs a contingency table from the input data, with rows formed by the levels of the classification variable and columns formed by the response variable values. The reference set for a given contingency table is the set of all contingency tables with the observed marginal row and column sums. Corresponding to this reference set, the network algorithm forms a directed acyclic network consisting of nodes in a number of stages. A path through the network corresponds to a distinct table in the reference set. The distances between nodes are defined so that the total distance of a path through the network is the corresponding value of the test statistic. At each node, the algorithm computes the shortest and longest path distances for all the paths that pass through that node. For the two-sample linear rank statistics, which can be expressed as a linear combination of cell frequencies multiplied by increasing row and column scores, PROC NPAR1WAY computes shortest and longest path distances using the algorithm given in Agresti, Mehta, and Patel (1990). For the multisample one-way test statistics, PROC NPAR1WAY computes an upper bound for the longest path and a lower bound for the shortest path, following the approach of Valz and Thompson (1994).

The longest and shortest path distances or bounds for a node are compared to the value of the test statistic to determine whether all paths through the node contribute to the \( p \)-value, none of the paths through the node contribute to the \( p \)-value, or neither of these situations occur. If all paths through the node contribute, the \( p \)-value is incremented accordingly, and these paths are eliminated from further analysis. If no paths contribute, these paths are eliminated from the analysis. Otherwise, the algorithm continues, still processing this node and the associated paths. The algorithm finishes when all nodes have been accounted for.

In applying the network algorithm, PROC NPAR1WAY uses full precision to represent all statistics, row and column scores, and other quantities involved in the computations. Although it is possible to use rounding to improve the speed and memory requirements of the algorithm, PROC NPAR1WAY does not do this since it can result in reduced accuracy of the \( p \)-values.

Definition of \( p \)-Values

For two-sample linear rank tests, PROC NPAR1WAY computes exact one-sided and two-sided \( p \)-values for each test specified in the EXACT statement. For the one-sided test, PROC NPAR1WAY displays the right-sided \( p \)-value when the observed value of the test statistic is greater than its expected value. The right-sided \( p \)-value is the sum of probabilities for those tables having a test statistic greater than or equal to the observed test statistic. Otherwise, when the test statistic is less than or equal to its expected value, PROC NPAR1WAY displays the left-sided \( p \)-value. The left-sided
The p-value is the sum of probabilities for those tables having a test statistic less than or equal to the one observed. The one-sided p-value $P_1$ can be expressed as

\[
P_1 = \text{Prob} \left( \text{Test Statistic} \geq S \right) \quad \text{if} \quad S > \text{Mean}
\]

\[
P_1 = \text{Prob} \left( \text{Test Statistic} \leq S \right) \quad \text{if} \quad S \leq \text{Mean}
\]

where $S$ is the observed value of the test statistic and Mean is the expected value of the test statistic under the null hypothesis. PROC NPAR1WAY computes the two-sided p-value as the sum of the one-sided p-value and the corresponding area in the opposite tail of the distribution of the statistic, equidistant from the expected value. The two-sided p-value $P_2$ can be expressed as

\[
P_2 = \text{Prob} \left( | \text{Test Statistic} - \text{Mean} | \geq | S - \text{Mean} | \right)
\]

For multisample data, the tests are based on one-way ANOVA statistics. For a test of this form, large values of the test statistic indicate a departure from the null hypothesis; the test is inherently two-sided. The exact p-value is the sum of probabilities for those tables having a test statistic greater than or equal to the value of the observed test statistic.

If you specify the POINT option in the EXACT statement, PROC NPAR1WAY also displays exact point probabilities for the test statistics. The exact point probability is the exact probability that the test statistic equals the observed value.

**Computational Resources**

PROC NPAR1WAY uses relatively fast and efficient algorithms for exact computations. These recently developed algorithms, together with improvements in computer power, make it feasible now to perform exact computations for data sets where previously only asymptotic methods could be applied. Nevertheless, there are still large problems that may require a prohibitive amount of time and memory for exact computations, depending on the speed and memory available on your computer. For large problems, consider whether exact methods are really needed or whether asymptotic methods might give results quite close to the exact results while requiring much less computer time and memory. When asymptotic methods may not be sufficient for such large problems, consider using Monte Carlo estimation of exact p-values, as described in the section “Monte Carlo Estimation” on page 3174.

A formula does not exist that can predict in advance how much time and memory are needed to compute an exact p-value for a certain problem. The time and memory required depend on several factors, including which test is being performed, the total sample size, the number of rows and columns, and the specific arrangement of the observations into table cells. Generally, larger problems (in terms of total sample size, number of rows, and number of columns) tend to require more time and memory. Additionally, for a fixed total sample size, time and memory requirements tend to increase as the number of rows and columns increase, since this corresponds to an increase in the number of tables in the reference set. Also for a fixed sample size, time
Chapter 52. The NPAR1WAY Procedure

and memory requirements increase as the marginal row and column totals become more homogeneous. Refer to Agresti, Mehta, and Patel (1990) and Gail and Mantel (1977).

At any time while PROC NPAR1WAY is computing exact p-values, you can terminate the computations by pressing the system interrupt key sequence (refer to the SAS Companion for your system) and choosing to stop computations. After you terminate exact computations, PROC NPAR1WAY completes all other remaining tasks. The procedure produces the requested output and reports missing values for any exact p-values not computed by the time of termination.

You can also use the MAXTIME= option in the EXACT statement to limit the amount of time PROC NPAR1WAY uses for exact computations. You specify a MAXTIME= value that is the maximum amount of time (in seconds) that PROC NPAR1WAY can use to compute an exact p-value. If PROC NPAR1WAY does not finish computing an exact p-value within that time, it terminates the computation and completes all other remaining tasks.

Monte Carlo Estimation

If you specify the MC option in the EXACT statement, PROC NPAR1WAY computes Monte Carlo estimates of the exact p-values instead of directly computing the exact p-values. Monte Carlo estimation can be useful for large problems that require a great amount of time and memory for exact computations but for which asymptotic approximations may not be sufficient. To describe the precision of each Monte Carlo estimate, PROC NPAR1WAY provides the asymptotic standard error and 100(1 − α)% confidence limits. The confidence level α is determined by the ALPHA= option in the EXACT statement, which, by default, equals 0.01, and produces 99% confidence limits. The N= option in the EXACT statement specifies the number of samples PROC NPAR1WAY uses for Monte Carlo estimation; the default is 10,000 samples. You can specify a larger value for n to improve the precision of the Monte Carlo estimates. Because larger values of n generate more samples, the computation time increases. Or you can specify a smaller value of n to reduce the computation time.

To compute a Monte Carlo estimate of an exact p-value, PROC NPAR1WAY generates a random sample of tables with the same total sample size, row totals, and column totals as the observed table. PROC NPAR1WAY uses the algorithm of Agresti, Wackerly, and Boyett (1979), which generates tables in proportion to their hypergeometric probabilities conditional on the marginal frequencies. For each sample table, PROC NPAR1WAY computes the value of the test statistic and compares it to the value for the observed table. When estimating a right-sided p-value, PROC NPAR1WAY counts all sample tables for which the test statistic is greater than or equal to the observed test statistic. Then the p-value estimate equals the number of these tables divided by the total number of tables sampled.

\[
\hat{P}_{MC} = \frac{M}{N}
\]

\[M = \text{number of samples with } (\text{Test Statistic} \geq t)\]

\[N = \text{total number of samples}\]

\[t = \text{observed Test Statistic}\]
PROC NPAR1WAY computes left-sided and two-sided $p$-value estimates in a similar manner. For left-sided $p$-values, PROC NPAR1WAY evaluates whether the test statistic for each sampled table is less than or equal to the observed test statistic. For two-sided $p$-values, PROC NPAR1WAY examines the sample test statistics according to the expression for $P_2$ given in the section “Definition of $p$-Values” on page 3172.

The variable $M$ is a binomial variable with $N$ trials and success probability $p$. It follows that the asymptotic standard error of the Monte Carlo estimate is

$$se(\hat{P}_{MC}) = \sqrt{\hat{P}_{MC} (1 - \hat{P}_{MC}) / (N - 1)}$$

PROC NPAR1WAY constructs asymptotic confidence limits for the $p$-values according to

$$\hat{P}_{MC} \pm z_{\alpha/2} \times se(\hat{P}_{MC})$$

where $z_{\alpha/2}$ is the $100(1 - \alpha/2)$ percentile of the standard normal distribution, and the confidence level $\alpha$ is determined by the ALPHA= option in the EXACT statement.

When the Monte Carlo estimate $\hat{P}_{MC}$ equals 0, then PROC NPAR1WAY computes the confidence limits for the $p$-value as

$$\left( 0, \; 1 - \alpha^{1/N} \right)$$

When the Monte Carlo estimate $\hat{P}_{MC}$ equals 1, then PROC NPAR1WAY computes the confidence limits as

$$\left( \alpha^{1/N}, \; 1 \right)$$

**Output Data Set**

The OUTPUT statement creates a SAS data set that contains statistics computed by PROC NPAR1WAY. You specify which statistics to store in the output data set, using options identical to those used in the PROC NPAR1WAY statement. When you specify one of these options in the OUTPUT statement, PROC NPAR1WAY includes all available statistics from that analysis in the output data set.

The output data set contains one observation for each analysis variable within a BY-group. The OUTPUT data set can include the following variables:

- BY variables
- _VAR_, which identifies the analysis variable
- variables containing the specified statistics
The following table lists the variable names and descriptions for all available statistics. Note that some statistics are available only for the two-sample case (where the classification variable groups the data into two classes). Other statistics are available only for the multisample case.

When you request exact \( p \)-values for certain analyses using the EXACT statement, PROC NPAR1WAY also includes those \( p \)-values in the output data set if you specify the corresponding analysis options in the OUTPUT statement. If you do not request exact \( p \)-values, then they do not appear in the output data set.

Monte Carlo estimates of exact \( p \)-values are not available in this output data set, but you can use the Output Delivery System (ODS) to store Monte Carlo estimates in a SAS data set. You can use the Output Delivery System to create a SAS data set from any piece of PROC NPAR1WAY output. For more information, see Table 52.6 on page 3184 and Chapter 14, “Using the Output Delivery System.”

* Statistic included only for two-sample cases
** Statistic included only for multisample cases
Displayed Output

If you specify the ANOVA option, PROC NPAR1WAY displays a Class Means table and an Analysis of Variance table for each response variable. The Class Means table includes the following information for each CLASS variable value, or level:

- N, the number of observations
- the Mean of the response variable

The Analysis of Variance table includes the following information for each Source of variation (Among classes, and Within classes):

- DF, the degrees of freedom associated with the source
- the Sum of Squares
- the Mean Square, the sum of squares divided by the degrees of freedom

The Analysis of Variance table also includes the following:

- the F Value for testing the hypothesis that the group means are equal. This is computed by dividing the Mean Square (Among) by the Mean Square (Within).
- Pr > F, the significance probability corresponding to the F Value

For each score type that you specify, PROC NPAR1WAY displays a Class Scores table. The available score types include Wilcoxon, median, Van der Waerden, Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and raw data scores. PROC NPAR1WAY assigns the specified scores to the response variable values, and classifies them according to the CLASS variable values. The Class Scores table includes the following information for each class:

- N, the number of observations
- Sum of Scores
- Expected Under H0, the expected sum of scores under the null hypothesis of no difference among classes
- Std Dev Under H0, the standard deviation under the null hypothesis
- Mean Score

When there are only two levels of the CLASS variable, PROC NPAR1WAY displays the following Two-Sample Test results for each analysis of scores:

- Statistic, which is the sum of scores for the class with the smaller sample size
- Z, the standardized test statistic, which has an asymptotic standard normal distribution under the null hypothesis
- One-Sided Pr < Z, or One-Sided Pr > Z, the asymptotic one-sided p-value, displayed as Pr < Z or Pr > Z, depending on whether Z is <= 0 or > 0
- Two-Sided Pr > |Z|, the asymptotic two-sided p-value
For Wilcoxon scores, PROC NPAR1WAY also displays a \( t \)-approximation for the two-sample test.

If you request an exact test by specifying the score type in the EXACT statement, PROC NPAR1WAY displays the following exact \( p \)-values for two-sample data:

- One-Sided \( Pr \leq S \), or One-Sided \( Pr \geq S \), the one-sided exact \( p \)-value, displayed as \( Pr \leq S \) or \( Pr \geq S \), depending on whether \( S \leq \text{Mean} \) or \( S > \text{Mean} \), where \( S \) is the test statistic and Mean is its expected value under the null hypothesis
- Point \( Pr = S \), the point probability, if you specify the POINT option in the EXACT statement
- Two-Sided \( Pr \geq |S - \text{Mean}| \), the two-sided exact \( p \)-value

If you request Monte Carlo estimates for the exact test by specifying the MC option in the EXACT statement, PROC NPAR1WAY displays the following information for two-sample data:

- Estimate of One-Sided \( Pr \leq S \) or One-Sided \( Pr \geq S \), the one-sided exact \( p \)-value, together with its Lower and Upper Confidence Limits
- Estimate of Two-Sided \( Pr \geq |S - \text{Mean}| \), the two-sided exact \( p \)-value, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimates
- Initial Seed used to compute the Monte Carlo estimates

For both two-sample and multisample data, PROC NPAR1WAY displays the following One-Way Analysis for each score type:

- Chi-Square, the one-way ANOVA statistic for testing the null hypothesis of no difference among classes
- DF, the degrees of freedom
- \( Pr > \text{Chi-Square} \), the asymptotic \( p \)-value

For multisample data, if you request an exact test by specifying the score type in the EXACT statement, PROC NPAR1WAY also displays the exact \( p \)-value as follows:

- Exact \( Pr \geq \text{Chi-Square} \)
- Exact \( Pr = \text{Chi-Square} \), the point probability, if you specify the POINT option in the EXACT statement
For multisample data, if you request a Monte Carlo estimate for the exact test by specifying the MC option in the EXACT statement, PROC NPAR1WAY displays the following information:

- Estimate of Pr >= Chi-Square, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimate
- Initial Seed used to compute the Monte Carlo estimate

If you specify the EDF option, PROC NPAR1WAY produces tables for the Kolmogorov-Smirnov Test, the Cramer-von Mises Test, and for two-sample data only, the Kuiper Test. The Kolmogorov-Smirnov Test table includes the following information for each CLASS variable value, or level:

- N, the number of observations
- EDF at Maximum, the value of the class EDF (empirical distribution function) at its maximum deviation from the pooled EDF
- Deviation from Mean at Maximum, the value of $\sqrt{n_i} \sqrt{F_i - F}$ at its maximum, where $n_i$ is the class sample size, $F_i$ is the class EDF, and $F$ is the pooled EDF

PROC NPAR1WAY displays the following Kolmogorov-Smirnov statistics:

- KS, the Kolmogorov-Smirnov statistic
- KSa, the asymptotic Kolmogorov-Smirnov statistic, where KSa = $\sqrt{n} KS$

For two-sample data, PROC NPAR1WAY displays the following Kolmogorov-Smirnov statistics:

- Pr > KSa, the asymptotic $p$-value for KSa, which equals Pr > D
- D = max |F1 - F2|, the two-sample Kolmogorov-Smirnov statistic

For two-sample data, if you specify the D option, PROC NPAR1WAY also displays the following one-sided Kolmogorov-Smirnov statistics and their asymptotic $p$-values:

- D+ = max (F1 - F2)
- Pr > D+
- D- = max(F2 - F1)
- Pr > D-
For two-sample data, if you request an exact Kolmogorov-Smirnov test by specifying the KS option in the EXACT statement, PROC NPAR1WAY displays the following exact p-values:

- Exact Pr >= D
- Exact Pr >= D+
- Exact Pr >= D-
- Exact Point Pr = D, Exact Point Pr = D+, and Exact Point Pr = D-, if you specify the POINT option in the EXACT statement

If you request Monte Carlo estimates for the two-sample exact Kolmogorov-Smirnov test, PROC NPAR1WAY displays the following information for two-sample data:

- Estimate of Pr >= D, together with its Lower and Upper Confidence Limits
- Estimate of Pr >= D+, together with its Lower and Upper Confidence Limits
- Estimate of Pr >= D-, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimates
- Initial Seed used to compute the Monte Carlo estimates

The Cramer-von Mises Test table includes the following information for each CLASS variable value, or level:

- N, the number of observations
- Summed Deviation from Mean, which is \( \sum_{j=1}^{p} t_j (F_i(x_j) - F(x_j))^2 \)

PROC NPAR1WAY also displays the following Cramer-von Mises statistics:

- CM, the Cramer-von Mises statistic
- CMa, the asymptotic Cramer-von Mises statistic, where CMa = \( n \) CM

For two-sample data, PROC NPAR1WAY displays the Kuiper Test table, which includes the following information for each class:

- N, the number of observations
- Deviation from Mean, which is \( \max_j |F_1(x_j) - F_2(x_j)| \)

PROC NPAR1WAY also displays the following Kuiper two-sample test statistics:

- K, the Kuiper two-sample test statistic
- Ka, the asymptotic Kuiper two-sample test statistic, where Ka = K \( \sqrt{n_1n_2/n} \)
- Pr > Ka
**ODS Table Names**

PROC NPAR1WAY assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

The WILCOXON, MEDIAN, VW, SAVAGE, and EDF options are the default if you do not specify any analysis options in the PROC NPAR1WAY statement.

** PROC NPAR1WAY produces this table only for multisample data.
Examples

Example 52.1. Two-Sample Location Tests and EDF Statistics

Fifty-nine female patients with rheumatoid arthritis who participated in a clinical trial were assigned to two groups, active and placebo. The response status (excellent=5, good=4, moderate=3, fair=2, poor=1) of each patient was recorded.

The following SAS statements create the data set Arthritis, which contains the observed status values for all the patients. The variable Treatment denotes the treatment received by a patient, and the variable Response contains the response status of the patient. The variable Freq contains the frequency of the observation, which is the number of patients with the Treatment and Response combination.

```sas
data Arthritis;
  input Treatment $ Response Freq @@;
datalines;
  Active 5 5 Active 4 11 Active 3 5 Active 2 1 Active 1 5
  Placebo 5 2 Placebo 4 4 Placebo 3 7 Placebo 2 7 Placebo 1 12
;
```

PROC NPAR1WAY tests the null hypothesis that there is no difference in the patient response status against an alternative hypothesis that the patient response status differs in the two treatment groups. The WILCOXON option requests the Wilcoxon test for difference in location, and the MEDIAN option requests the median test for difference in location. The EDF option requests empirical distribution function statistics. The variable Treatment is the CLASS variable, and the VAR statement specifies that the variable Response is the response variable.

```sas
proc npar1way wilcoxon median edf data=Arthritis;
  class Treatment;
  var Response;
  freq Freq;
run;
```

Output 52.1.1 shows the results of the Wilcoxon analysis. The Wilcoxon two-sample test statistic equals 999.0, which is the sum of the Wilcoxon scores for the smaller sample (Active). This sum is greater than 810.0, its expected value under the null hypothesis of no difference between the two samples Active and Placebo. The one-sided p-value is 0.0016, which shows that the patient response for the Active treatment is significantly more than for the Placebo group.
Output 52.1.1. Wilcoxon Two-Sample Test

</table>

Kuiper Two-Sample Test (Asymptotic)
K 0.405093  Ka 1.550191  Pr > Ka 0.1409

Output 52.1.3 shows empirical distribution function statistics comparing these two samples. The asymptotic p-value for the Kolmogorov-Smirnov test is 0.0164. This indicates rejection of the null hypothesis that the distributions are identical for the two groups.
Example 52.2. The Exact Wilcoxon Two-Sample Test

Researchers conducted an experiment to compare the effects of two stimulants. Thirteen randomly selected subjects received the first stimulant and six randomly selected subjects received the second stimulant. The reaction times (in minutes) were measured while the subjects were under the influence of the stimulants.

The following SAS statements create the data set `React`, which contains the observed reaction times for each stimulant. The variable `Stim` represents Stimulant 1 or 2. The variable `Time` contains the reaction times observed for subjects under the stimulant.

```sas
data React;
  input Stim Time @@;
datalines;
  1 1.94 1 1.94 1 2.92 1 2.92 1 2.92 1 2.92 1 3.27
  1 3.27 1 3.27 1 3.27 1 3.70 1 3.70 1 3.74
  2 3.27 2 3.27 2 3.27 2 3.70 2 3.70 2 3.74
;
```

PROC NPAR1WAY tests the null hypothesis that there is no difference between the effects of the two stimulants against an alternative hypothesis that stimulant 1 has smaller reaction times than stimulant 2. The WILCOXON option specifies that Wilcoxon scores are to be used. The CLASS statement specifies that the variable `Stim` determines the classes. The VAR statement identifies `Time` as the response variable. The EXACT option requests the exact p-values. Since the sample size is small, the normal approximation may not be completely accurate, and it is appropriate to compute the exact test.

```sas
proc npar1way wilcoxon data=React;
  class Stim;
  var Time;
  exact;
run;
```

Output 52.2.1 displays the results of the Wilcoxon two-sample test. The Wilcoxon statistic equals 79.50. Since this value is greater than 60.0, the expected value under the null hypothesis, PROC NPAR1WAY displays the right-sided p-values. The one-sided exact p-value equals 0.0527, which is not significant at the 0.05 level. The normal approximation yields a one-sided p-value of 0.0421, which is significant at the 0.05 level. Thus, the normal approximation may result in rejection of the null hypothesis, while the exact test may result in acceptance.
Output 52.2.1. Wilcoxon Two-Sample Test

Example 52.3. The Exact Savage Multisample Test

A researcher conducting a laboratory experiment randomly assigned 15 mice to receive one of three drugs. The survival time (in days) was then recorded.

The following SAS statements create the data set Mice, which contains the observed survival times for all the mice. The variable Trt denotes the treatment received by a mouse. The variable Days contains the number of days the mouse survived.

```sas
data Mice;
  input Trt $ Days @@;
datalines;
1 1 1 1 1 3 1 3 1 4
2 3 2 4 2 4 2 4 2 15
3 4 3 4 3 10 3 10 3 26;
```

```
PROC NPAR1WAY tests the null hypothesis that there is no difference in the survival times among the three drugs against an alternative hypothesis of difference among the drugs. The SAVAGE option specifies that Savage scores are to be used. The variable Trt is the CLASS variable, and the VAR statement specifies that the variable Days is the response variable. The EXACT statement requests the exact test.

```sas
proc npar1way savage data=Mice;
class Trt;
var Days;
exact;
run;
```

Output 52.3.1. Savage Multisample Test

<table>
<thead>
<tr>
<th>Trt</th>
<th>N</th>
<th>Sum of Scores</th>
<th>Expected Under H0</th>
<th>Std Dev Under H0</th>

REFERENCES .............................................. 3210
The ORTHOREG procedure fits general linear models by the method of least squares. Other SAS/STAT software procedures, such as GLM or REG, fit the same types of models, but PROC ORTHOREG can produce more accurate estimates than other regression procedures when your data are ill conditioned. Instead of collecting crossproducts, PROC ORTHOREG uses Gentleman-Givens transformations to update and compute the upper triangular matrix $R$ of the QR decomposition of the data matrix, with special care for scaling (Gentleman 1972; 1973). This method has the advantage over other orthogonalization methods (for example, Householder transformations) of not requiring the data matrix to be stored in memory.

The standard SAS regression procedures (REG and GLM) are very accurate for most problems. However, if you have very ill-conditioned data, these procedures can produce estimates that yield an error sum of squares very close to the minimum but still different from the exact least-squares estimates. Normally, this coincides with estimates that have very high standard errors. In other words, the numerical error is much smaller than the statistical standard error.

Note that PROC ORTHOREG fits models by the method of linear least squares, minimizing the sum of the squared residuals for predicting the responses. It does not perform the modeling method known as “orthogonal regression,” which minimizes a different criterion (the distance between the X/Y points taken together and the regression line.)

Longley Data

The labor statistics data set of Longley (1967) is noted for being ill conditioned. Both the ORTHOREG and GLM procedures are applied for comparison (only portions of the PROC GLM results are shown). Note: The results from this example vary from machine to machine, depending on floating-point configuration.

The following statements read the data into the SAS data set Longley.
title 'PROC ORTHOREG used with Longley data';
data Longley;
   input Employment Prices GNP Jobless Military PopSize Year;

;run;

The data set contains one dependent variable, Employment (total derived employment) and six independent variables: Prices (GNP implicit price deflator with year 1954 = 100), GNP (gross national product), Jobless (unemployment), Military (size of armed forces), PopSize (non-institutional population aged 14 and over), and Year (year).

The following statements use the ORTHOREG procedure to model the Longley data using a quadratic model in each independent variable, without interaction:

    proc orthoreg data=Longley;
    model Employment = Prices Prices*Prices
                      GNP GNP*GNP
                      Jobless Jobless*Jobless
                      Military Military*Military
                      PopSize PopSize*PopSize
                      Year Year*Year;
    run;

Figure 53.1 shows the resulting analysis.

**Figure 53.1.** PROC ORTHOREG Results

The estimates in Figure 53.1 compare very well with the best estimates available; for additional information, refer to Longley (1967) and Beaton et al. (1976).

The following statements request the same analysis from the GLM procedure:

```latex
proc glm data=Longley;  
  model Employment = Prices Prices*Prices GNP GNP*GNP Jobless Jobless*Jobless Military Military*Military PopSize PopSize*PopSize Year Year*Year;  
  ods select OverallANOVA FitStatistics ParameterEstimates Notes;  
run;
```

**Figure 53.2** contains the over-all ANOVA table and the parameter estimates produced by PROC GLM. Notice that the ORTHOREG fit achieves a somewhat smaller root
mean square error (RMSE) and also that the GLM procedure detects spurious singularities.

**PROC ORTHOREG used with Longley data**

NOTE: The X’X matrix has been found to be singular, and a generalized inverse was used to solve the normal equations. Terms whose estimates are followed by the letter ‘B’ are not uniquely estimable.

**Figure 53.2.** Partial PROC GLM Results

**Syntax**

The following statements are available in PROC ORTHOREG.

```plaintext
PROC ORTHOREG < options >;
   MODEL dependent=independents < / option >;
   BY variables;
   CLASS variables < / option >;
   WEIGHT variable;
```
The BY, CLASS, MODEL, and WEIGHT statements are described after the PROC ORTHOREG statement.

**PROC ORTHOREG Statement**

```plaintext
PROC ORTHOREG < options > ;
```

The PROC ORTHOREG statement has the following options:

- **DATA=SAS-data-set**
  specifies the input SAS data set to use. By default, the procedure uses the most recently created SAS data set. The data set specified cannot be a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set.

- **NOPRINT**
  suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

- **ORDER=DATA | FORMATTED | FREQ | INTERNAL**
  specifies the order in which you want the levels of the classification variables (specified in the CLASS statement) to be sorted. This ordering determines which parameters in the model correspond to each level in the data. Note that the ORDER= option applies to the levels for all classification variables. The exception is the default ORDER=FORMATTED for numeric variables for which you have supplied no explicit format. In this case, the levels are ordered by their internal value. Note that this represents a change from previous releases for how class levels are ordered. In releases previous to Version 8, numeric class levels with no explicit format were ordered by their BEST12. formatted values, and in order to revert to the previous ordering you can specify this format explicitly for the affected classification variables. The change was implemented because the former default behavior for ORDER=FORMATTED often resulted in levels not being ordered numerically and usually required the user to intervene with an explicit format or ORDER=INTERNAL to get the more natural ordering.

The ORDER= option can take the following values.

<table>
<thead>
<tr>
<th>Value of ORDER=</th>
<th>Levels Sorted By</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>order of appearance in the input data set</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value</td>
</tr>
<tr>
<td>FREQ</td>
<td>descending frequency count; levels with the most observations come first in the order</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>unformatted value</td>
</tr>
</tbody>
</table>

If you omit the ORDER= option, PROC ORTHOREG orders by the external formatted value.
OUTEST=SAS-data-set
produces an output data set containing the parameter estimates, the BY variables, and the special variables _TYPE_ (value PARMS), _NAME_ (blank), _RMSE_ (root mean squared error), and Intercept.

SINGULAR=s
specifies a singularity criterion \( s \geq 0 \) for the inversion of the triangular matrix \( R \).
By default, SINGULAR=10E−12.

BY Statement

BY variables ;
You can specify a BY statement with PROC ORTHOREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.
If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the ORTHOREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

CLASS Statement

CLASS variables < / option > ;
The CLASS statement names the classification variables to be used in the model. Typical class variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.
By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. In releases prior to Version 9, class levels were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the TRUNCATE option on the CLASS statement. In any case, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the SAS Procedures Guide.
and the discussions for the FORMAT statement and SAS formats in SAS Language Reference: Dictionary.

You can specify the following option in the CLASS statement after a slash (/):

TRUNCATE
specifies that class levels should be determined using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to Version 9.

**MODEL Statement**

```plaintext
MODEL dependent=independents < / option > ;
```

The MODEL statement names the dependent variable and the independent effects. Only one MODEL statement is allowed. The specification of effects and the parameterization of the linear model is the same as in the GLM procedure; see Chapter 32, “The GLM Procedure,” for further details.

The following option can be used in the MODEL statement:

NOINT
omits the intercept term from the model.

**WEIGHT Statement**

```plaintext
WEIGHT variable ;
```

A WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least-squares regression. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE). For a more complete description of the WEIGHT statement, see the “WEIGHT Statement” section on page 1782 in Chapter 32, “The GLM Procedure.”

**Details**

**Missing Values**

If there is a missing value for any model variable in an observation, the entire observation is dropped from the analysis.

**Output Data Set**

The OUTEST= option produces a TYPE=EST output SAS data set containing the BY variables, parameter estimates, and four special variables. For each new value of the BY variables, PROC ORTHOREG outputs an observation to the OUTTEST= data set. The variables in the data set are as follows:

- parameter estimates for all variables listed in the MODEL statement
BY variables
• __TYPE__, which is a character variable with the value PARMS for every observation
• __NAME__, which is a character variable left blank for every observation
• __RMSE__, which is the root mean squared error (the estimate of the standard deviation of the true errors)
• Intercept, which is the estimated intercept. This variable does not exist in the OUTEST= data set if the NOINT option is specified.

Displayed Output
PROC ORTHOREG displays the parameter estimates and associated statistics. These include the following:

• overall model analysis of variance, including the error mean square, which is an estimate of \( \sigma^2 \) (the variance of the true errors), and the overall \( F \) test for a model effect
• root mean squared error, which is an estimate of the standard deviation of the true errors. It is calculated as the square root of the mean squared error.
• R-square, which is a measure between 0 and 1 that indicates the portion of the total variation that is attributed to the fit
• estimates for the parameters in the linear model

The table of parameter estimates consists of

• the terms used as regressors, including the Intercept, identifying the intercept parameter
• degrees of freedom (DF) for the variable. There is one degree of freedom for each parameter being estimated unless the model is not full rank.
• estimated linear coefficients
• estimates of the standard errors of the parameter estimates
• the critical \( t \) values for testing whether the parameters are zero. This is computed as the parameter estimate divided by its standard error.
• the two-sided \( p \)-value for the \( t \)-test, which is the probability that a \( t \)-statistic would obtain a greater absolute value than that observed given that the true parameter is zero

ODS Table Names
PROC ORTHOREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”
Example 53.1. Precise Analysis of Variance

The data for the following example are from Powell et al. (1982). In order to calibrate an instrument for measuring atomic weight, 24 replicate measurements of the atomic weight of silver (chemical symbol $\text{Ag}$) are made with the new instrument and with a reference instrument.

Note: The results from this example vary from machine to machine depending on floating-point configuration.

The following statements read the measurements for the two instruments into the SAS data set $\text{AgWeight}$.

```sas
title 'Atomic Weight of Silver by Two Different Instruments';
data AgWeight;
   input Instrument AgWeight @@;
datalines;
1 107.8681568 1 107.8681465 1 107.8681572 1 107.8681785
1 107.8681446 1 107.8681903 1 107.8681526 1 107.8681494
1 107.8681616 1 107.8681587 1 107.8681519 1 107.8681486
1 107.8681419 1 107.8681569 1 107.8681508 1 107.8681672
1 107.8681385 1 107.8681518 1 107.8681662 1 107.8681424
1 107.8681360 1 107.8681333 1 107.8681610 1 107.8681477
2 107.8681079 2 107.8681344 2 107.8681513 2 107.8681197
2 107.8681604 2 107.8681385 2 107.8681642 2 107.8681365
2 107.8681151 2 107.8681082 2 107.8681517 2 107.8681448
2 107.8681198 2 107.8681482 2 107.8681334 2 107.8681609
2 107.8681101 2 107.8681512 2 107.8681469 2 107.8681360
2 107.8681254 2 107.8681261 2 107.8681450 2 107.8681368
;
```

Notice that the variation in the atomic weight measurements is several orders of magnitude less than their mean. This is a situation that can be difficult for standard, regression-based analysis-of-variance procedures to handle correctly.
The following statements invoke the ORTHOREG procedure to perform a simple one-way analysis of variance, testing for differences between the two instruments.

```
proc orthoreg data=AgWeight;
class Instrument;
  model AgWeight = Instrument;
run;
```

Output 53.1.1 shows the resulting analysis.

**Output 53.1.1.** PROC ORTHOREG Results for Atomic Weight Example

</tr>
</tbody>
</table>

The mean difference between instruments is about $1.74 \times 10^{-5}$ (the value of the (Instrument='1') parameter in the parameter estimates table), whereas the level of background variation in the measurements is about $1.51 \times 10^{-5}$ (the value of the root mean squared error). The difference is significant, with a $p$-value of 0.0002.

The National Institute of Standards and Technology (1998) has provided certified ANOVA values for this data set. The following statements use ODS to examine the ANOVA values produced by both the ORTHOREG and GLM procedures more precisely for comparison with the NIST-certified values:
ods listing close;
ods output ANOVA = OrthoregANOVA
    FitStatistics = OrthoregFitStat;

proc orthoreg data=AgWeight;
    class Instrument;
    model AgWeight = Instrument;
run;

ods output OverallANOVA = GLMANOVA
    FitStatistics = GLMFitStat;
proc glm data=AgWeight;
    class Instrument;
    model AgWeight = Instrument;
run;
ods listing;

data _null_; set OrthoregANOVA (in=inANOVA)
    OrthoregFitStat(in=inFitStat);
    if (inANOVA) then do;
        if (Source = 'Model') then put "Model SS: " ss e20.;
        if (Source = 'Error') then put "Error SS: " ss e20.;
    end;
    if (inFitStat) then do;
        if (Statistic = 'Root MSE') then
            put "Root MSE: " nValue1 e20.;
        if (Statistic = 'R-Square') then
            put "R-Square: " nValue1 best20.;
    end;

data _null_; set GLMANOVA (in=inANOVA)
    GLMFitStat(in=inFitStat);
    if (inANOVA) then do;
        if (Source = 'Model') then put "Model SS: " ss e20.;
        if (Source = 'Error') then put "Error SS: " ss e20.;
    end;
    if (inFitStat) then put "Root MSE: " RootMSE e20.;
    if (inFitStat) then put "R-Square: " RSquare best20.;
run;

In releases of SAS/STAT software prior to Version 8, PROC GLM gave much less accurate results than PROC ORTHOREG, as shown in the following tables, which compare the ANOVA values certified by NIST with those produced by the two procedures.
While the ORTHOREG values and the GLM values for Version 8 are quite close to the certified ones, the GLM values for prior releases are not. In fact, since the model sum of squares is so small, in prior releases the GLM procedure set it (and consequently $R^2$) to zero.

**Example 53.2. Wampler Data**

This example applies the ORTHOREG procedure to a collection of data sets noted for being ill conditioned. The OUTEST= data set is used to collect the results for comparison with values certified to be correct by the National Institute of Standards and Technology (1998).

**Note:** The results from this example vary from machine to machine depending on floating-point configuration.

The data are from Wampler (1970). The independent variates for all five data sets are $x^i, i = 1, \ldots, 5$, for $x = 0, 1, \ldots, 20$. Two of the five dependent variables are exact linear functions of the independent terms:

$$
    y_1 = 1 + x + x^2 + x^3 + x^4 + x^5 \\
    y_2 = 1 + 0.1x + 0.01x^2 + 0.001x^3 + 0.0001x^4 + 0.00001x^5
$$

The other three dependent variables have the same mean value as $y_1$, but with nonzero errors.

$$
    y_3 = y_1 + e \\
    y_4 = y_1 + 100e \\
    y_5 = y_1 + 10000e
$$

where e is a vector of values with standard deviation 2044, chosen to be orthogonal to the mean model for $y_1$.

|
The following statements create a SAS data set `Wampler` containing the Wampler data, run a SAS macro program using PROC ORTHOREG to fit a fifth-order polynomial in $x$ to each of the Wampler dependent variables, and collect the results in a data set named `ParmEst`.

```sas
data Wampler;
  do x=0 to 20;
    input e @@;
    y1 = 1 + x + x*x + x*x*x + x*x*x*x + x*x*x*x*x;
    y2 = 1 + .1 *x + .01 *x*x + .001*x*x*x + .0001*x*x*x*x + .00001*x*x*x*x*x;
    y3 = y1 + e;
    y4 = y1 + 100*e;
    y5 = y1 + 10000*e;
    output;
  end;
datalines;
759  -2048  2048  -2048  2523  -2048  2048  -2048  1838  -2048  2048  -2048  1838  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048  -2048  2048

%macro WTest;
  data ParmEst; if (0); run;
  %do i = 1 %to 5;
    proc orthoreg data=Wampler outest=ParmEst&i noprint;
      model y&i = x x*x x*x*x x*x*x*x x*x*x*x*x;
      data ParmEst&i; set ParmEst&i; Dep = "y&i";
      data ParmEst; set ParmEst ParmEst&i;
      label Col1='x' Col2='x**2' Col3='x**3' Col4='x**4' Col5='x**5';
    run;
  %end;
%mend;
%WTest;
```

Instead of displaying the raw values of the RMSE and parameter estimates, use a further DATA step to compute the deviations from the values certified to be correct by the National Institute of Standards and Technology (1998).

```sas
data ParmEst; set ParmEst;
  if (Dep = 'y1') then
    _RMSE_ = _RMSE_ - 0.0000000000000000;
  else if (Dep = 'y2') then
    _RMSE_ = _RMSE_ - 0.0000000000000000;
  else if (Dep = 'y3') then
    _RMSE_ = _RMSE_ - 2360.14502379268;
  else if (Dep = 'y4') then
    _RMSE_ = _RMSE_ - 236014.502379268;
  else if (Dep = 'y5') then
    _RMSE_ = _RMSE_ - 23601450.2379268;
```

if (Dep ^= 'y2') then do;
    Intercept = Intercept - 1.00000000000000;
    Col1 = Col1 - 1.00000000000000;
    Col2 = Col2 - 1.00000000000000;
    Col3 = Col3 - 1.00000000000000;
    Col4 = Col4 - 1.00000000000000;
    Col5 = Col5 - 1.00000000000000;
end;
else do;
    Intercept = Intercept - 1.00000000000000;
    Col1 = Col1 - 0.100000000000000;
    Col2 = Col2 - 0.100000000000000e-1;
    Col3 = Col3 - 0.100000000000000e-2;
    Col4 = Col4 - 0.100000000000000e-3;
    Col5 = Col5 - 0.100000000000000e-4;
end;

proc print data=ParmEst label noobs;
title 'Wampler data: Deviations from Certified Values';
format _RMSE_ Intercept Col1-Col5 e9.;
var Dep _RMSE_ Intercept Col1-Col5;
run;

The results, shown in Output 53.2.1, indicate that the values computed by PROC ORTHOREG are quite close to the NIST-certified values.

REFERENCES .............................................................. 3329
The analysis of survival data requires special techniques because the data are almost always incomplete, and familiar parametric assumptions may be unjustifiable. Investigators follow subjects until they reach a prespecified endpoint (for example, death). However, subjects sometimes withdraw from a study, or the study is completed before the endpoint is reached. In these cases, the survival times (also known as failure times) are censored; subjects survived to a certain time beyond which their status is unknown. The uncensored survival times are sometimes referred to as event times. Methods for survival analysis must account for both censored and uncensored data.

There are many types of models that have been used for survival data. Two of the more popular types of models are the accelerated failure time model (Kalbfleisch and Prentice 1980) and the Cox proportional hazards model (Cox 1972). Each has its own assumptions on the underlying distribution of the survival times. Two closely related functions often used to describe the distribution of survival times are the survivor function and the hazard function (see the section “Failure Time Distribution” on page 3239 for definitions). The accelerated failure time model assumes a parametric form for the effects of the explanatory variables and usually assumes a parametric form for the underlying survivor function. Cox’s proportional hazards model also assumes a parametric form for the effects of the explanatory variables, but it allows an unspecified form for the underlying survivor function.

The PHREG procedure performs regression analysis of survival data based on the Cox proportional hazards model. Cox’s semiparametric model is widely used in the analysis of survival data to explain the effect of explanatory variables on hazard rates. The survival time of each member of a population is assumed to follow its own hazard function, \( \lambda_i(t) \), expressed as

\[
\lambda_i(t) = \lambda(t; Z_i) = \lambda_0(t) \exp(Z_i'\beta)
\]

where \( \lambda_0(t) \) is an arbitrary and unspecified baseline hazard function, \( Z_i \) is the vector of explanatory variables for the \( i \)th individual, and \( \beta \) is the vector of unknown regression parameters associated with the explanatory variables. The vector \( \beta \) is assumed to be the same for all individuals. The survivor function can be expressed as

\[
S(t; Z_i) = [S_0(t)]^{\exp(Z_i'\beta)}
\]

where \( S_0(t) = \exp(-\int_0^t \lambda_0(u)du) \) is the baseline survivor function. To estimate \( \beta \), Cox (1972; 1975) introduced the partial likelihood function, which eliminates the unknown baseline hazard \( \lambda_0(t) \) and accounts for censored survival times.
The partial likelihood of Cox also allows time-dependent explanatory variables. An explanatory variable is time-dependent if its value for any given individual can change over time. Time-dependent variables have many useful applications in survival analysis. You can use a time-dependent variable to model the effect of subjects changing treatment groups. Or you can include time-dependent variables such as blood pressure or blood chemistry measures that vary with time during the course of a study. You can also use time-dependent variables to test the validity of the proportional hazards model.

An alternative way to fit models with time-dependent explanatory variables is to use the counting process style of input. The counting process formulation enables PROC PHREG to fit a superset of the Cox model, known as the multiplicative hazards model. This extension also includes recurrent events data and left truncation of failure times. The theory of these models is based on the counting process pioneered by Andersen and Gill (1982), and the model is often referred to as the Andersen-Gill Model.

Multivariate failure time data arise when each study subject can potentially experience several events (for instance, multiple infections after surgery) or when there exists some natural or artificial clustering of subjects (for instance, a litter of mice) that induces dependence among the failure times of the same cluster. Data in the former situation are referred to as multiple events data, which include recurrent events data as a special case; data in the latter situation are referred to as clustered data. You can use PROC PHREG to carry out various methods for analyzing these data.

The population under study may consist of a number of subpopulations, each of which has its own baseline hazard function. PROC PHREG performs a stratified analysis to adjust for such subpopulation differences. Under the stratified model, the hazard function for the \( j \)th individual in the \( i \)th stratum is expressed as

\[
\lambda_{ij}(t) = \lambda_{i0}(t) \exp(Z_{ij}'\beta)
\]

where \( \lambda_{i0}(t) \) is the baseline hazard function for the \( i \)th stratum, and \( Z_{ij} \) is the vector of explanatory variables for the individual. The regression coefficients are assumed to be the same for all individuals across all strata.

Ties in the failure times may arise when the time scale is genuinely discrete or when survival times generated from the continuous-time model are grouped into coarser units. The PHREG procedure includes four methods of handling ties. The \textit{discrete} logistic model is available for discrete time-scale data. The other three methods apply to continuous time-scale data. The \textit{exact} method computes the exact conditional probability under the model that the set of observed tied event times occurs before all the censored times with the same value or before larger values. \textit{Breslow} and \textit{Efron} methods provide approximations to the exact method.

Variable selection is a typical exploratory exercise in multiple regression when the investigator is interested in identifying important prognostic factors from a large number of candidate variables. The PHREG procedure provides four model selection methods: forward selection, backward elimination, stepwise selection, and best subset selection. The best subset selection method is based on the likelihood score.
statistic. This method identifies a specified number of best models containing one, two, three variables and so on, up to the single model containing all of the explanatory variables.

The PHREG procedure also enables you to

- include an offset variable in the model
- weight the observations in the input data
- test linear hypotheses about the regression parameters
- perform conditional logistic regression analysis for matched case-control studies
- create a SAS data set containing survivor function estimates, residuals, and regression diagnostics
- create a SAS data set containing survival distribution estimates and confidence interval for the survivor function at each event time for a given realization of the explanatory variables

PROC PHREG can also be used to fit the multinomial logit choice model to discrete choice data. See [http://support.sas.com/techsup/tnote/tnote_stat.html#market] for more information on discrete choice modeling and the multinomial logit model. Look for the latest “Discrete Choice” report.

The remaining sections of this chapter contain information on how to use PROC PHREG, information on the underlying statistical methodology, and some sample applications of the procedure. The “Getting Started” section on page 3217 introduces PROC PHREG with two examples. The “Syntax” section on page 3221 describes the syntax of the procedure. The “Details” section on page 3239 summarizes the statistical techniques employed in PROC PHREG. The “Examples” section on page 3272 includes eight additional examples of useful applications. Experienced SAS/STAT software users may decide to proceed to the “Syntax” section, while other users may choose to read both the “Getting Started” and “Examples” sections before proceeding to “Syntax” and “Details.”

Experimental graphics are now available in PROC PHREG for model assessment. For more information, see the section “ODS Graphics” on page 3271.

### Getting Started

PROC PHREG syntax is similar to that of the other regression procedures in the SAS System. For simple uses, only the PROC PHREG and MODEL statements are required.

Consider the following data from (Kalbfleisch and Prentice 1980). Two groups of rats received different pretreatment regimes and then were exposed to a carcinogen. Investigators recorded the survival times of the rats from exposure to mortality from vaginal cancer. Four rats died of other causes, so their survival times are censored. Interest lies in whether the survival curves differ between the two groups.
The data set Rats contains the variable Days (the survival time in days), the variable Status (the censoring indicator variable: 0 if censored and 1 if not censored), and the variable Group (the pretreatment group indicator).

data Rats;
  label Days = 'Days from Exposure to Death';
  input Days Status Group @@;
datalines;
  143 1 0  164 1 0  188 1 0  188 1 0
  190 1 0  192 1 0  206 1 0  209 1 0
  213 1 0  216 1 0  220 1 0  227 1 0
  230 1 0  234 1 0  246 1 0  265 1 0
  304 1 0  216 0 0  244 0 0  142 1 1
  156 1 1  163 1 1  198 1 1  205 1 1
  232 1 1  232 1 1  233 1 1  233 1 1
  233 1 1  233 1 1  239 1 1  240 1 1
  261 1 1  280 1 1  280 1 1  296 1 1
  296 1 1  323 1 1  204 0 1  344 0 1
;run;

In the MODEL statement, the response variable, Days, is crossed with the censoring variable, Status, with the value that indicates censoring enclosed in parentheses (0). The values of Days are considered censored if the value of Status is 0; otherwise, they are considered event times.

proc phreg data=Rats;
  model Days*Status(0)=Group;
run;

Results of the PROC PHREG analysis appear in Figure 54.1. Since Group takes only two values, the null hypothesis for no difference between the two groups is identical to the null hypothesis that the regression coefficient for Group is 0. All three tests in the “Testing Global Null Hypothesis: BETA=0” table (see the section “Testing the Global Null Hypothesis” on page 3246) suggest that the survival curves for the two pretreatment groups may not be the same. In this model, the hazards ratio (or risk ratio) for Group, defined as the exponentiation of the regression coefficient for Group, is the ratio of the hazard functions between the two groups. The estimate is 0.551, implying that the hazard function for Group=1 is smaller than that for Group=0. In other words, rats in Group=1 lived longer than those in Group=0.

Figure 54.1. Comparison of Two Survival Curves

In this example, the comparison of two survival curves is put in the form of a proportional hazards model. This approach is essentially the same as the log-rank (Mantel-Haenszel) test. In fact, if there are no ties in the survival times, the likelihood score test in the Cox regression analysis is identical to the log-rank test. The advantage of the Cox regression approach is the ability to adjust for the other variables by including them in the model. For example, the present model could be expanded by including a variable that contains the initial body weights of the rats.
Next, consider a simple test of the validity of the proportional hazards assumption. The proportional hazards model for comparing the two pretreatment groups is given by the following:

\[
\lambda(t) = \begin{cases} 
\lambda_0(t) & \text{if } \text{GROUP} = 0 \\
\lambda_0(t)e^{\beta_1} & \text{if } \text{GROUP} = 1
\end{cases}
\]

The ratio of hazards is \(e^{\beta_1}\), which does not depend on time. If the hazard ratio changes with time, the proportional hazards model assumption is invalid. Simple forms of departure from the proportional hazards model can be investigated with the following time-dependent explanatory variable \(x = x(t):\)

\[
x(t) = \begin{cases} 
0 & \text{if } \text{GROUP} = 0 \\
\log(t) - 5.4 & \text{if } \text{GROUP} = 1
\end{cases}
\]

Here, \(\log(t)\) is used instead of \(t\) to avoid numerical instability in the computation. The constant, 5.4, is the average of the logs of the survival times and is included to improve interpretability. The hazard ratio in the two groups then becomes \(e^{\beta_1 - 5.4/\hat{\beta}_2 t^{\hat{\beta}_2}}\), where \(\hat{\beta}_2\) is the regression parameter for the time-dependent variable \(x\). The term \(e^{\beta_1}\) represents the hazard ratio at the geometric mean of the survival times. A nonzero value of \(\beta_2\) would imply an increasing \((\beta_2 > 0)\) or decreasing \((\beta_2 < 0)\) trend in the hazard ratio with time.

The MODEL statement in this analysis also includes the time-dependent explanatory variable \(X\), which is defined within the procedure by the programming statement that follows the MODEL statement. At each event time, subjects in the risk set (those alive just before the event time) have their \(X\) values changed accordingly.

```plaintext
proc phreg data=Rats;
  model Days*Status(0)=Group X;
  X=Group*(log(Days) - 5.4);
run;
```

### Figure 54.2. A Simple Test of Trend in the Hazard Ratio

The analysis of the parameter estimates is displayed in Figure 54.2. The Wald chi-square statistic for testing the null hypothesis that \(\beta_2 = 0\) is 0.0158. The statistic is not statistically significant when compared to a chi-square distribution with one degree of freedom \((p = 0.8999)\). Thus, you can conclude that there is no evidence of an increasing or decreasing trend over time in the hazard ratio. See the “Examples” section beginning on page 3272 for additional illustrations of PROC PHREG usage.
Syntax

The following statements are available in PROC PHREG.

```
PROC PHREG < options > ;
   ASSESS keyword < / options > ;
   MODEL response < *censor(list) > = variables < /options > ;
   < programming statements >
   STRATA variable < (list) > < . . . variable < (list) > </option > ;
   < label: > TEST equation1 < , . . . , equationk > </option > ;
   FREQ variable ;
   WEIGHT variable < /option > ;
   ID variables ;
   OUTPUT < OUT=SAS-data-set >
       < keyword=name . . . keyword=name ></options > ;
   BASELINE < OUT=SAS-data-set >
       < COVARIATES=SAS-data-set >
       < keyword=name . . . keyword=name ></options > ;
   BY variables ;
```

The PROC PHREG statement invokes the procedure. All other statements except the MODEL statement are optional. Items within < > are optional, and there is no required order for the statements following the PROC PHREG statement. The MODEL statement specifies the variables that define the survival time, the censoring variable, and the explanatory variables. The STRATA statement specifies a variable or set of variables defining the strata for the analysis. The TEST statement contains equations that define linear hypotheses concerning the model parameters. The ID statement specifies the variables with values that are used to label the observations. The OUTPUT and BASELINE statements create data sets containing the survival estimates. DATA step programming statements can be included to create time-dependent explanatory variables.

PROC PHREG Statement

```
PROC PHREG < options > ;
```

You can specify the following options in the PROC PHREG statement.

**COVOUT**

adds the estimated covariance matrix of the parameter estimates to the OUTTEST= data set. The COVOUT option has no effect unless the OUTTEST= option is specified.

**COVM**

requests the model-based covariance matrix (which is the inverse of the observed information matrix) be presented and used in the analysis if the COVS option is also specified. The COVM option has no effect if the COVS option is not specified.
COVSANDWICH < (AGGREGATE) >
COVS < (AGGREGATE) >
requests the robust sandwich estimate of Lin and Wei (1989) for the covariance matrix. When this option is specified, this robust sandwich estimate is used in the Wald tests for testing the global null hypothesis, null hypotheses of individual parameters, and the hypotheses in the TEST statements. In addition, a modified score test is computed in the testing of the global null hypothesis, and the parameter estimates table has an additional StdErrRatio column, which contains the ratios of the robust estimate of the standard error relative to the corresponding model-based estimate. Optionally, you can specify the keyword AGGREGATE enclosed in parentheses after the COVSANDWICH (or COVS) option, which requests a summing up of the score residuals for each distinct ID pattern in the computation of the robust sandwich covariance estimate. This AGGREGATE option has no effects if the ID statement is not specified.

DATA= SAS-data-set
names the SAS data set containing the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

MULTIPASS
requests that, for each Newton-Raphson iteration, PROC PHREG recompiles the risk sets corresponding to the event times for the (start,stop) style of response and re-computes the values of the time-dependent variables defined by the programming statements for each observation in the risk sets. If the MULTIPASS option is not specified, PROC PHREG computes all risk sets and all the variable values and saves them into a utility file. The MULTIPASS option decreases required disk space at the expense of increased execution time; however, for very large data, it may actually save time since it is time consuming to write and read large utility files. This option has an effect only when the (start,stop) style of response is used or when there are time-dependent explanatory variables.

NOPRINT
suppresses all displayed output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

NOSUMMARY
suppresses the display of the event and censored observation frequencies.

OUTEST= SAS-data-set
creates an output SAS data set that contains estimates of the regression coefficients. If you use the COVOUT option, the data set also contains the estimated covariance matrix of the parameter estimates. The data set includes

- any BY variables specified
- _TIES_, a character variable of length 8 with four possible values: BRESLOW, DISCRETE, EFRON, and EXACT. These are the four values of the TIES= option in the MODEL statement.
- _TYPE_, a character variable of length 8 with two possible values: PARMS for parameter estimates or COV for covariance estimates. If both the COVM and COVS options are specified in the PROC LIFETEST statement along with the COVOUT option, _TYPE_ = COVM for the model-based covariance estimates and _TYPE_ = COVS for the robust sandwich covariance estimates.

- _STATUS_, a character variable indicating whether the estimates have converged

- _NAME_, a character variable containing the name of the TIME variable for the row of parameter estimates and the name of each explanatory variable to label the rows of covariance estimates

- one variable for each explanatory variable in the MODEL statement. In a forward, backward, or stepwise regression analysis, if an explanatory variable is not included in the final model, the corresponding parameter estimate and covariances are set to missing.

- _LNLIKEL_, a numeric variable containing the last computed value of the log likelihood

**SIMPLE**

displays simple descriptive statistics (mean, standard deviation, minimum, and maximum) for each explanatory variable in the MODEL statement.

**ASSESS Statement (Experimental)**

```
ASSESS < VAR=(list) > < PH > < /options > ;
```

The ASSESS statement performs the graphical and numerical methods of Lin, Wei, and Ying (1993) for checking the adequacy of the Cox regression model. The methods are derived from cumulative sums of martingale residuals over follow-up times or covariate values. You can assess the functional form of a covariate or you can check the proportional hazards assumption for each covariate in the Cox model. PROC PHREG uses the experimental ODS graphics for the graphical displays. For specific information about the experimental graphics that is available in PROC PHREG, see the section “ODS Graphics” on page 3271. You must specify at least one of the following to create an analysis.

**VAR=(list)**

specifies the list of explanatory variables for which their functional forms are assessed. For each variable on the list, the observed cumulative martingale residuals are plotted against the values of the explanatory variable along with 20 (or n if NPATHS=n is specified) simulated residual patterns.

**PROPORTIONALHAZARDS PH**

requests the checking of the proportional hazards assumption. For each explanatory variable in the model, the observed score process component is plotted against the follow-up time along with 20 (or n if NPATHS=n is specified) simulated patterns.

The following options can be specified after a slash (/).
NPATHS=n
specifies the number of simulated residual patterns to be displayed in a cumulative martingale residual plot or a score process plot. The default is \( n=20 \).

CRPANEL
requests that a plot with four panels, each containing the observed cumulative martingale residuals and two simulated residual patterns, be created.

RESAMPLE < =n >
requests that the Kolmogorov-type supremum test be computed on 1,000 simulated patterns or on \( n \) simulated patterns if \( n \) is specified.

SEED=n
specifies an integer seed for the random number generator used in creating simulated realizations for plots and for the Kolmogorov-type supremum tests. Specifying a seed enables you to reproduce identical graphs and \( p \)-values for the model assessments from the same PHREG specification. If the SEED= option is not specified, or if you specify a nonpositive seed, a random seed is derived from the time of day.

**BASELINE Statement**

```
BASELINE < OUT= SAS-data-set >< COVARIATES= SAS-data-set >
< keyword=name ... keyword=name > < /options > ;
```

The BASELINE statement creates a new SAS data set that contains the survivor function estimates at the event times of each stratum for every pattern of explanatory variable values \((x)\) given in the COVARIATES= data set. By default, the data set also contains the survivor function estimates corresponding to the means of the explanatory variables \((x = \overline{x})\) for each stratum. If you want only these estimates, you can omit the COVARIATES= option. No BASELINE data set is created if the model contains a time-dependent variable defined by means of programming statement.

The following list explains specifications in the BASELINE statement.

**OUT=SAS-data-set**
names the output BASELINE data set. If you omit the OUT= option, the data set is created and given a default name using the DATA\textit{n} convention.

**COVARIATES=SAS-data-set**
names the SAS data set containing the set of explanatory variable values for which the survivor functions are estimated. There must be a corresponding variable in the COVARIATES= data set for each explanatory variable in the final model.

**keyword=name**
specifies the statistics included in the BASELINE data set and assigns names to the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic. The keywords and the corresponding statistics are

- **CMF** cumulative mean function estimate for recurrent events data. Specifying CMF=_ALL_ is equivalent to specifying CMF=CMF, STDCMF=StdErrCMF, LOWERCMF=LowerCMF,
and \text{UPPERCMF}=\text{UpperCMF}. \text{Nelson} (2002) \text{ refers to the mean function estimate as MCF (mean cumulative function).}

\text{CUMHAZ} \text{ cumulative hazard function estimate for recurrent events data. Specifying CMFHAZ=} \text{_ALL_ is equivalent to specifying CUMHAZ=} \text{CumHaz, STDCUMHAZ=} \text{StdErrCumHaz, LOWERCUMHAZ=} \text{LowerCumHaz, and UPPERCUMHAZ=} \text{UpperCumHaz.}

\text{LOGLOGS} \text{ log of the negative log of SURVIVAL}

\text{LOGSURV} \text{ log of SURVIVAL}

\text{LOWER | L} \text{ lower pointwise confidence limit for the survivor function. The confidence level is determined by the ALPHA=} \text{ option.}

\text{LOWERCUMHAZ} \text{ lower pointwise confidence limit for the cumulative hazard function. The confidence level is determined by the ALPHA=} \text{ option.}

\text{STDERR} \text{ standard error of the survivor function estimator}

\text{STDCMF} \text{ standard error of the cumulative mean function estimator}

\text{STDCUMHAZ} \text{ standard error of the cumulative hazard function estimator}

\text{STDXBETA} \text{ standard error of the linear predictor estimator, } \sqrt{x'\hat{\text{V}}(\hat{\beta})x}

\text{SURVIVAL} \text{ survivor function estimate } \hat{S}(t) = [\hat{S}_0(t)]^{\exp(x'\hat{\beta})}

\text{Specifying SURVIVAL=} \text{_ALL_ is equivalent to specifying SURVIVAL=} \text{Survival, STDERR=} \text{StdErrSurvival, LOWER=} \text{LowerSurvival, and UPPER=} \text{UpperSurvival.}

\text{UPPER | U} \text{ upper pointwise confidence limit for the survivor function. The confidence level is determined by the ALPHA=} \text{ option.}

\text{UPPERCMF} \text{ upper pointwise confidence limit for the cumulative mean function. The confidence level is determined by the ALPHA=} \text{ option.}

\text{UPPERCUMHAZ} \text{ upper pointwise confidence limit for the cumulative hazard function. The confidence level is determined by the ALPHA=} \text{ option.}

\text{XBETA} \text{ estimate of the linear predictor, } x'\hat{\beta}

The following options can appear in the BASELINE statement after a slash (/).

\text{ALPHA=}value \text{ specifies the significance level of the confidence interval for the survivor function. The value must be between 0 and 1. The default is 0.05, which results in a 95\% confidence interval.}

\text{CLTYPE=}method \text{ specifies the method used to compute the confidence limits for } S(t, z), \text{ the survivor function for a subject with a fixed covariate vector } z \text{ at event time } t. \text{ The CLTYPE=} \text{ option can take the following values:}
LOG specifies that the confidence limits for $\log(S(t, z))$ are to be computed using the normal theory approximation. The confidence limits for $S(t, z)$ are obtained by back-transforming the confidence limits for $\log(S(t, z))$. The default is CLTYPE=LOG.

LOGLOG specifies that the confidence limits for $\log(-\log(S(t, z)))$ are to be computed using normal theory approximation. The confidence limits for $S(t, z)$ are obtained by back-transforming the confidence limits for $\log(-\log(S(t, z)))$.

NORMAL specifies that the confidence limits for $S(t, z)$ are to be computed directly using normal theory approximation.

METHOD=method specifies the method used to compute the survivor function estimates. The two available methods are

CH | EMP | NELSON specifies that the Nelson (empirical) cumulative hazard function estimate of the survivor function is to be computed; that is, the survivor function is estimated by exponentiating the negative empirical cumulative hazard function.

PL specifies that the product-limit estimate of the survivor function is to be computed. The default is METHOD=PL.

NOMEAN excludes the survivor function estimates corresponding to the sample means of the explanatory variables.

The METHOD= and CLTYPE= options apply only to the survival estimates. For recurrent events data, both CMF= and CUMHAZ= statistics are the Nelson estimators, but their standard error are not the same. Confidence limits for the cumulative mean function and cumulative hazard function are based on the log transform.

**BY Statement**

BY variables;

You can specify a BY statement with PROC PHREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PHREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
• Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in SAS Language Reference: Contents. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

**FREQ Statement**

```
FREQ variable < /option > ;
```

The `variable` in the FREQ statement identifies the variable (in the input data set) containing the frequency of occurrence of each observation. PROC PHREG treats each observation as if it appears $n$ times, where $n$ is the value of the FREQ variable for the observation. If not an integer, the frequency value is truncated to an integer. If the frequency value is missing, the observation is not used in the estimation of the regression parameters.

The following option can be specified in the FREQ statement after a slash (/):

```
NOTRUNCATE
```

specifies that frequency values are not truncated to integers.

**ID Statement**

```
ID variables ;
```

The ID statement specifies additional variables for identifying observations in the input data. These variables are placed in the OUT= data set created by the OUTPUT statement. In the computation of the robust sandwich variance estimate, you can aggregate over distinct values of these ID variables.

Only variables in the input data set can be included in the ID statement.

**MODEL Statement**

```
MODEL response < *censor ( list ) > = variables < /options > ;

MODEL (t1, t2) < *censor(list) > = variables < /options > ;
```

The MODEL statement identifies the variables to be used as the failure time variables, the optional censoring variable, and the explanatory variables. Two forms of MODEL syntax can be specified; the first form allows one response variable, while the second form allows two variables for the counting process style of input (see the section “Counting Process Style of Input” on page 3241 for more information).

In the first MODEL statement, preceding the equal sign, is the name of the failure time variable. This can optionally be followed by an asterisk, the name of the censoring variable, and a list of censoring values (separated by blanks or commas if there is more than one) enclosed in parentheses. If the censoring variable takes on one of these values, the corresponding failure time is considered to be censored. The
variables following the equal sign are the explanatory variables (sometimes called independent variables or covariates) for the model.

Instead of a single failure time variable, the second MODEL statement identifies a pair of failure time variables. Their names are enclosed in parentheses, and they signify the endpoints of a semi-closed interval \((t_1, t_2]\) during which the subject is at risk. If the censoring variable takes on one of the censoring values, the time \(t_2\) is considered to be censored.

The censoring variable and the explanatory variables must be numeric. The failure time variables must contain nonnegative values. Any observation with a negative failure time is excluded from the analysis, as is any observation with a missing value for any of the variables listed in the MODEL statement.

You can specify the following options in the MODEL statement.

**Ties-Handling Option**

**TIES=** method

specifies how to handle ties in the failure time. The TIES= option can take the following values:

- **BRESLOW** uses the approximate likelihood of Breslow (1974). This is the default value.
- **DISCRETE** replaces the proportional hazards model by the discrete logistic model

\[
\frac{\lambda(t; z)}{1 - \lambda(t; z)} = \frac{\lambda_0(t)}{1 - \lambda_0(t)} \exp(z' \beta)
\]

where \(\lambda_0(t)\) and \(h(t; z)\) are discrete hazard functions.

- **EFRON** uses the approximate likelihood of Efron (1977).
- **EXACT** computes the exact conditional probability under the proportional hazards assumption that all tied event times occur before censored times of the same value or before larger values. This is equivalent to summing all terms of the marginal likelihood for \(\beta\) that are consistent with the observed data (Kalbfleisch and Prentice 1980; DeLong, Guirguis, and So 1994).

The EXACT method may take a considerable amount of computer resources. If ties are not extensive, the EFRON and BRESLOW methods provide satisfactory approximations to the EXACT method for the continuous time-scale model. In general, Efron’s approximation gives results that are much closer to the EXACT method results than Breslow’s approximation does. If the time scale is genuinely discrete, you should use the DISCRETE method. The DISCRETE method is also required in the analysis of case-control studies when there is more than one case in a matched set. If there are no ties, all four methods result in the same likelihood and yield identical estimates. The default, TIES=BRESLOW, is the most efficient method when there are no ties.
**Model-Specification Options**

- **ENTRYTIME=variable** specifies the name of the variable that represents the left truncation time. This option has no effect when the counting process style of input is specified. See the section “Left Truncation of Failure Times” on page 3263 for more information.

- **NOFIT** performs the global score test, which tests the joint significance of all the explanatory variables in the MODEL statement. No parameters are estimated. If the NOFIT option is specified along with other MODEL statement options, NOFIT takes precedence, and all other options are ignored except the TIES= option.

- **OFFSET=name** specifies the name of an offset variable, which is an explanatory variable with a regression coefficient fixed as one. This option can be used to incorporate risk weights for the likelihood function.

- **SELECTION=method** specifies the method used to select the model. The methods available are:
  - **BACKWARD | B** requests backward elimination.
  - **FORWARD | F** requests forward selection.
  - **NONE | N** fits the complete model specified in the MODEL statement. This is the default value.
  - **SCORE** requests best subset selection. It identifies a specified number of models with the highest score chi-square statistic for all possible model sizes ranging from one explanatory variable to the total number of explanatory variables listed in the MODEL statement.
  - **STEPWISE | S** requests stepwise selection.

  For more information, see the section “Variable Selection Methods” on page 3264.

**Model-Building Options**

The following options enable you to provide additional specifications for the BACKWARD, FORWARD, SCORE, and STEPWISE model selection methods. They have no effect when SELECTION=NONE. Only the INCLUDE=, START=, STOP=, and BEST= options work with the SCORE method.

- **BEST=n** is used exclusively with the SCORE model selection method. The BEST=n option specifies that n models with the highest score chi-square statistics are to be displayed for each model size. If the option is omitted and there are no more than 10 explanatory variables, then all possible models are listed for each model size. If the option is omitted and there are more than 10 explanatory variables, then the number of models selected for each model size is, at most, equal to the number of explanatory variables
listed in the MODEL statement. See Example 54.2 on page 3279 for an illustration of the SCORE selection method and the BEST= option.

DETAILS
produces a detailed display at each step of the model-building process. It produces an “Analysis of Variables Not in the Model” table before displaying the variable selected for entry for FORWARD or STEPWISE selection. For each model fitted, it produces the “Analysis of Maximum Likelihood Estimates” table. See Example 54.1 on page 3272 for a discussion of these tables.

INCLUDE=n
includes the first n explanatory variables listed in the MODEL statement in every model. The value for n ranges from 1 to s, where s is the number of explanatory variables in the MODEL statement. The default value of n is 0.

MAXSTEP=n
specifies the maximum number of times the explanatory variables can move in and out of the model before the STEPWISE model-building process ends. The default value for n is twice the number of explanatory variables in the MODEL statement. The option has no effect for other model selection methods.

SEQUENTIAL
forces variables to be added to the model in the order specified in the MODEL statement or to be eliminated from the model in the reverse order specified in the MODEL statement.

SLE=value
SLENTRY=value
specifies the significance level (a value between 0 and 1) for entering an explanatory variable into the model in the FORWARD or STEPWISE method. For all variables not in the model, the one with the smallest p-value is entered if the p-value is less than or equal to the specified significance level. The default value is 0.05.

SLS=value
SLSTAY=value
specifies the significance level (a value between 0 and 1) for removing an explanatory variable from the model in the BACKWARD or STEPWISE method. For all variables in the model, the one with the largest p-value is removed if the p-value exceeds the specified significance level. The default value is 0.05.

START=n
begins the FORWARD, BACKWARD, or STEPWISE model selection process with the first n explanatory variables listed in the MODEL statement. The value for n ranges from 0 to s, where s is the total number of explanatory variables in the MODEL statement. The default value of n is s for the BACKWARD method and 0 for the FORWARD and STEPWISE methods. Note that START=n specifies only that the first n explanatory variables appear in the first model, while INCLUDE=n specifies that the first n explanatory variables be included in every model. For the SCORE method, START=n specifies that the smallest models contain n explanatory variables, where n ranges from 1 to s. The default value of n is 1.
STOP=n
specifies the maximum (FORWARD method) or minimum (BACKWARD method) number of explanatory variables to be included in the final model. The value for n ranges from 0 to s, where s is the number of explanatory variables in the MODEL statement. The default value of n is 0 for the BACKWARD method and s for the FORWARD method. For the SCORE method, STOP=n specifies that the largest models contain n explanatory variables, where n ranges from 1 to s. The default value of n is s. The STOP= option has no effect for the STEPWISE method.

STOPRES SR
specifies that the addition and deletion of variables are to be based on the result of the likelihood score test for testing the joint significance of variables not in the model. This score chi-square statistic is referred to as the residual chi-square. In the FORWARD method, the STOPRES option enters the explanatory variables into the model one at a time until the residual chi-square becomes insignificant (that is, until the p-value of the residual chi-square exceeds the SLENTRY= value). In the BACKWARD method, the STOPRES option removes variables from the model one at a time until the residual chi-square becomes significant (that is, until the p-value of the residual chi-square becomes less than the SLSTAY= value). The STOPRES option has no effect for the STEPWISE method.

Optimization Options

Four convergence criteria are allowed: ABSFCONV=, FCONV=, GCONV=, and XCONV=. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is GCONV=1E−8.

ABSFCONV=value
specifies the absolute function convergence criterion. Termination requires a small change in the objective function (log partial likelihood function) in subsequent iterations,

$$|l_k - l_{k-1}| < value$$

where $l_k$ is the value of the objective function at iteration $k$.

CONVERGELIKE=value
is the same as specifying the ABSFCONV= option.

CONVERGEPARM=value
is the same as specifying the XCONV= option.

FCONV=value
specifies the relative function convergence criterion. Termination requires a small relative change in the objective function (log partial likelihood function) in subsequent iterations,
\begin{align*}
\frac{|l_k - l_{k-1}|}{|l_{k-1}| + 1E - 6} < value
\end{align*}

where \(l_k\) is the value of the objective function at iteration \(k\).

**GCONV=**\(value\)

specifies the relative gradient convergence criterion. Termination requires that the normalized prediction function reduction is small,

\begin{align*}
\frac{g_k H_k^{-1} g_k}{|l_k| + 1E - 6} < value
\end{align*}

where \(l_k\) is the log partial likelihood, \(g_k\) is the gradient vector (first partial derivatives of the log partial likelihood), and \(H_k\) is the negative Hessian matrix (second partial derivatives of the log partial likelihood), all at iteration \(k\).

**MAXITER=**\(n\)

specifies the maximum number of iterations allowed. The default value for \(n\) is 25. If convergence is not attained in \(n\) iterations, the displayed output and all data sets created by PROC PHREG contain results that are based on the last maximum likelihood iteration.

**RIDGING=**\(ABSOLUTE \mid RELATIVE \mid NONE\)

specifies the technique to improve the log-likelihood when its value is worse than that of the previous step. For RIDGING=ABSOLUTE, the diagonal elements of the negative (expected) Hessian are inflated by adding the ridge value. For RIDGING=RELATIVE, the diagonal elements are inflated by the factor equal to 1 plus the ridge value. For RIDGING=NONE, the crude line-search method of taking half a step is used instead of ridging.

**SINGULAR=**\(value\)

specifies the singularity criterion for determining linear dependencies in the set of explanatory variables. The default value is \(10^{-12}\).

**XCONV=**\(value\)

specifies the relative parameter convergence criterion. Termination requires a small relative parameter change in subsequent iterations,

\begin{align*}
\max_i |\delta_{k}^{(i)}| < value
\end{align*}

where

\[
\delta_{k}^{(i)} = \begin{cases} 
\frac{\theta_{k}^{(i)} - \theta_{k-1}^{(i)}}{|\theta_{k-1}^{(i)}|} & |\theta_{k-1}^{(i)}| < .01 \\
\frac{\theta_{k}^{(i)} - \theta_{k-1}^{(i)}}{\theta_{k-1}^{(i)}} & \text{otherwise}
\end{cases}
\]

where \(\theta_{k}^{(i)}\) is the estimate of the \(i\)th parameter at iteration \(k\).
Display Options

**ALPHA=** `value`

sets the significance level used for the confidence limits for the hazards ratios. The value must be between 0 and 1. The default value is 0.05, which results in the calculation of a 95% confidence interval. This option has no effect unless the RISKLIMITS option is specified.

**CORRB**

displays the estimated correlation matrix of the parameter estimates.

**COVB**

displays the estimated covariance matrix of the parameter estimates.

**ITPRINT**

displays the iteration history, including the last evaluation of the gradient vector.

**RISKLIMITS**

**RL**

displays, for each explanatory variable, the $100(1 - \alpha)\%$ confidence limits for the hazards ratio ($e^{\hat{\beta}_i}$). The value for $\alpha$ is determined by the ALPHA= option.

OUTPUT Statement

```
OUTPUT <OUT= SAS-data-set >
   < keyword=name ... keyword=name > < /options > ;
```

The OUTPUT statement creates a new SAS data set containing statistics calculated for each observation. These can include the estimated linear predictor ($z_j^T\hat{\beta}$) and its standard error, survival distribution estimates, residuals, and influence statistics. In addition, this data set includes the time variable, the explanatory variables listed in the MODEL statement, the censoring variable (if specified), and the BY, STRATA, FREQ, and ID variables (if specified).

For observations with missing values in the time variable or any explanatory variables, the output statistics are set to missing. However, for observations with missing values only in the censoring variable or the FREQ variable, survival estimates are still computed. Therefore, by adding observations with missing values in the FREQ variable or the censoring variable, you can compute the survivor function estimates for new observations or for settings of explanatory variables not present in the data without affecting the model fit.

No OUTPUT data set is created if the model contains a time-dependent variable defined by means of programming statements.

The following list explains specifications in the OUTPUT statement.

**OUT=** `SAS-data-set`

names the output data set. If you omit the OUT= option, the OUTPUT data set is created and given a default name using the DATA$n$ convention.
keyword=name

specifies the statistics included in the OUTPUT data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and either a variable or a list of variables to contain the statistic. The keywords that accept a list of variables are DFBETA, RESSCH, RESSCO, and WTRESSCH. For these keywords, you can specify as many names in name as the number of explanatory variables specified in the MODEL statement. If you specify k names and k is less than the total number of explanatory variables, only the changes for the first k parameter estimates are output. The keywords and the corresponding statistics are as follows:

DFBETA approximate changes in the parameter estimates \( \hat{\beta} - \hat{\beta}(j) \) when the jth observation is omitted. These variables are a weighted transform of the score residual variables and are useful in assessing local influence and in computing robust variance estimates.

LD approximate likelihood displacement when the observation is left out. This diagnostic can be used to assess the impact of each observation on the overall fit of the model.

LMAX relative influence of observations on the overall fit of the model. This diagnostic is useful in assessing the sensitivity of the fit of the model to each observation.

LOGLOGS log of the negative log of SURVIVAL

LOGSURV log of SURVIVAL

NUM_LEFT number of subjects at risk at the observation time \( \tau_j \) (or at the right endpoint of the at risk interval when a counting process MODEL specification is used)

RESDEV deviance residual \( \hat{D}_j \). This is a transform of the martingale residual to achieve a more symmetric distribution.

RESSCH Schoenfeld residuals. These residuals are useful in assessing the proportional hazards assumption.

RESSCO score residuals. These residuals are a decomposition of the first partial derivative of the log likelihood. They can be used to assess the leverage exerted by each subject in the parameter estimation. They are also useful in constructing robust sandwich variance estimators.
STDXBETA  
standard error of the estimated linear predictor, \( \sqrt{z_j' \hat{V}(\hat{\beta}) z_j} \)

SURVIVAL  
survivor function estimate \( \hat{S}_j = [\hat{S}_0(\tau_j)] \exp(z_j' \hat{\beta}) \), where \( \tau_j \) is the observation time

WTRESSCH  
weighted Schoenfeld residuals. These residuals are useful in investigating the nature of nonproportionality if the proportional hazard assumption does not hold.

XBETA  
estimate of the linear predictor, \( z_j' \hat{\beta} \)

The following options can appear in the OUTPUT statement after a slash (/).

**ORDER=sort_order**

specifies the order of the observations in the OUTPUT data set. Available values for *sort_order* are

- **DATA** requests that the output observations be sorted the same as the input data set.
- **SORTED** requests that the output observations be sorted by strata and descending order of the time variable within each stratum.

The default is ORDER=DATA.

**METHOD=method**

specifies the method used to compute the survivor function estimates. The two available methods are

- **CH | EMP** specifies that the empirical cumulative hazard function estimate of the survivor function is to be computed; that is, the survivor function is estimated by exponentiating the negative empirical cumulative hazard function.
- **PL** specifies that the product-limit estimate of the survivor function is to be computed. The default is METHOD=PL.

**Programming Statements**

Programming statements are used to create or modify the values of the explanatory variables in the MODEL statement. They are especially useful in fitting models with time-dependent explanatory variables. Programming statements can also be used to create explanatory variables that are not time dependent. For example, you can create indicator variables from a categorical variable and incorporate them into the model.

PROC PHREG programming statements cannot be used to create or modify the values of the response variable, the censoring variable, the frequency variable, or the strata variables.
The following DATA step statements are available in PROC PHREG:

\begin{verbatim}
ABORT
ARRAY
  assignment statements
CALL
DO
  iterative DO
DO UNTIL
DO WHILE
END
GOTO
IF-THEN/ELSE
LINK-RETURN
PUT
SELECT
SUM statement
\end{verbatim}

By default, the PUT statement in PROC PHREG writes to the Output window instead of the Log window. If you want the results of the PUT statements to go to the Log window, add the following statement before the PUT statements:

\begin{verbatim}
FILE LOG;
\end{verbatim}

DATA step functions are also available. Use these programming statements the same way you use them in the DATA step. For detailed information, refer to \textit{SAS Language Reference: Dictionary}.

Consider the following example of using programming statements in PROC PHREG. Suppose blood pressure is measured at multiple times during the course of a study investigating the effect of blood pressure on some survival time. By treating the blood pressure as a time-dependent explanatory variable, you are able to use the value of the most recent blood pressure at each specific point of time in the modeling process rather than using the initial blood pressure or the final blood pressure. The values of the following variables are recorded for each patient, if they are available. Otherwise, the variables contain missing values.

- \textbf{Time} \hspace{1cm} survival time
- \textbf{Censor} \hspace{1cm} censoring indicator (with 0 as the censoring value)
- \textbf{BP0} \hspace{1cm} blood pressure on entry to the study
- \textbf{T1} \hspace{1cm} time 1
- \textbf{BP1} \hspace{1cm} blood pressure at T1
- \textbf{T2} \hspace{1cm} time 2
- \textbf{BP2} \hspace{1cm} blood pressure at T2

The following programming statements create a variable \textbf{BP}. At each time \textbf{T}, the value of \textbf{BP} is the blood pressure reading for that time, if available. Otherwise, it is the last blood pressure reading.
proc phreg;
  model Time*Censor(0)=BP;
  BP = BP0;
  if Time>=T1 and T1^=. then BP=BP1;
  if Time>=T2 and T2^=. then BP=BP2;
run;

For other illustrations of using programming statements, see the “Getting Started” section on page 3217 and Example 54.4 on page 3285.

**STRATA Statement**

**STRATA** *variable < (list)> < ... variable < (list) >> < /option > ;

The proportional hazards assumption may not be realistic for all data. If so, it may still be reasonable to perform a stratified analysis. The STRATA statement names the variables that determine the stratification. Strata are formed according to the nonmissing values of the STRATA variables unless the MISSING option is specified. In the STRATA statement, *variable* is a variable with values that are used to determine the strata levels, and *list* is an optional list of values for a numeric variable. Multiple variables can appear in the STRATA statement.

The values for *variable* can be formatted or unformatted. If the variable is a character variable, or if the variable is numeric and no list appears, then the strata are defined by the unique values of the variable. If the variable is numeric and is followed by a list, then the levels for that variable correspond to the intervals defined by the list. The corresponding strata are formed by the combination of levels and unique values. The list can include numeric values separated by commas or blanks, *value to value* by *value* range specifications, or combinations of these.

For example, the specification

```
strata age (5, 10 to 40 by 10) sex ;
```

indicates that the levels for *age* are to be less than 5, 5 to 10, 10 to 20, 20 to 30, 30 to 40, and greater than 40. (Note that observations with exactly the cutpoint value fall into the interval preceding the cutpoint.) Thus, with the *sex* variable, this STRATA statement specifies 12 strata altogether.

The following option can be specified in the STRATA statement after a slash (/).

**MISSING**

allows missing values (‘.’ for numeric variables and blanks for character variables) as valid STRATA variable values. Otherwise, observations with missing STRATA variable values are deleted from the analysis.
TEST Statement

< label: > TEST equation1 <, . . ., equationk > /option > ;

The TEST statement tests linear hypotheses about the regression coefficients. PROC PHREG performs a Wald test for the joint hypothesis specified in a single TEST statement. Each equation specifies a linear hypothesis; multiple equations (rows of the joint hypothesis) are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output, and should always be included. You can submit multiple TEST statements.

The form of an equation is as follows:

\[
\text{term} < \pm \text{term} \ldots > < = < \pm \text{term} < \pm \text{term} \ldots > > >
\]

here term is a variable or a constant or a constant times a variable. The variable is any explanatory variable in the MODEL statement. When no equal sign appears, the expression is set to 0. The following code illustrates possible uses of the TEST statement:

```
proc phreg;
  model time= a1 a2 a3 a4;
  Test1: Test a1, a2;
  Test2: Test a1=0,a2=0;
  Test3: Test a1=a2=a3;
  Test4: Test a1=a2,a2=a3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

The following options can be specified in the TEST statement after a slash (/).

AVERAGE enables you to assess the average effect of the variables in the given TEST statement. An overall estimate of the treatment effect is computed as a weighted average of the treatment coefficients as illustrated in the following code:

```
TREATMENT: test trt1, trt2, trt3, trt4 / average;
```

Let \( \beta_1, \beta_2, \beta_3 \) and \( \beta_4 \) be corresponding parameters for trt1, trt2, trt3, and trt4, respectively. Let \( \hat{\beta} = (\hat{\beta}_1, \hat{\beta}_2, \hat{\beta}_3, \hat{\beta}_4)' \) be estimated coefficient vector and let \( \hat{V}(\hat{\beta}) \) be the corresponding variance estimate. Assuming \( \beta_1 = \beta_2 = \beta_3 = \beta_4 \). The average treatment effect is estimated by \( c'\hat{\beta} \), where \( c = [1, \hat{V}^{-1}(\hat{\beta})1_4]^{-1}\hat{V}^{-1}(\hat{\beta})1_4 \) and \( 1_4 = (1, 1, 1, 1)' \).

E specifies that the linear coefficients and constants be printed. When the AVERAGE option is specified along with the E option, the optimal weights of the average effect are also printed in the same tables as the coefficients.
PRINT displays intermediate calculations. This includes $L \hat{V}(\hat{\beta})L'$ bordered by $(L\hat{\beta} - c)$, and $[L \hat{V}(\hat{\beta})L']^{-1}$ bordered by $[L \hat{V}(\hat{\beta})L']^{-1}(L\hat{\beta} - c)$, where $L$ is a matrix of linear coefficients and $c$ is a vector of constants. See the section “Testing Linear Hypotheses about Regression Coefficients” on page 3247.

**WEIGHT Statement**

```
WEIGHT variable < /option > ;
```

The `variable` in the WEIGHT statement identifies the variable in the input data set that contains the case weights. When the WEIGHT statement appears, each observation in the input data set is weighted by the value of the WEIGHT variable. The WEIGHT values can be nonintegral and are not truncated. Observations with negative, zero or missing values for the WEIGHT variable are not used in the model fitting. When the WEIGHT statement is not specified, each observation is assigned a weight of 1. The WEIGHT statement is available for TIES=BRESLOW and TIES=EFRON only.

The following option can be specified in the WEIGHT statement after a slash (/):

```
NORMALIZE NORM
```

causes the weights specified by the WEIGHT `variable` to be normalized so that they add up the actual sample size. With this option, the estimated covariance matrix of the parameter estimators is invariant to the scale of the WEIGHT variable.

**Details**

**Failure Time Distribution**

Let $T$ be a nonnegative random variable representing the failure time of an individual from a homogeneous population. The survival distribution function (also known as the survivor function) of $T$ is written as

$$S(t) = \Pr(T \geq t)$$

A mathematically equivalent way of specifying the distribution of $T$ is through its hazard function. The hazard function $\lambda(t)$ specifies the instantaneous failure rate at $t$. If $T$ is a continuous random variable, $\lambda(t)$ is expressed as

$$\lambda(t) = \lim_{\Delta t \to 0^+} \frac{\Pr(t \leq T < t + \Delta t \mid T \geq t)}{\Delta t} = \frac{f(t)}{S(t)}$$

where $f(t)$ is the probability density function of $T$. If $T$ is discrete with masses at $x_1 < x_2 < \ldots$, then $\lambda(t)$ is given by

$$\lambda(t) = \sum_j \lambda_j \delta(t - x_j)$$
where
\[
\delta(u) = \begin{cases} 
0 & \text{if } u < 0 \\
1 & \text{otherwise}
\end{cases}
\]

\[
\lambda_j = \Pr(T = x_j \mid T \geq x_j) = \frac{\Pr(T = x_j)}{S(x_j)}
\]

for \( j = 1, 2, \ldots \)

**Partial Likelihood Function for the Cox Model**

Let \( Z_l(t) \) denote the vector explanatory variables for the \( l \)th individual at time \( t \). Let \( t_1 < t_2 < \ldots < t_k \) denote the \( k \) distinct, ordered event times. Let \( d_i \) denote the multiplicity of failures at \( t_i \); that is, \( d_i \) is the size of the set \( D_i \) of individuals that fail at \( t_i \). Let \( w_l \) be the weight associated with the \( l \)th individual. Using this notation, the likelihood functions used in PROC PHREG to estimate \( \beta \) are described in the following sections.

**Continuous Time Scale**

Let \( R_i \) denote the risk set just before the \( i \)th ordered event time \( t_i \). Let \( R_i^* \) denote the set of individuals whose event or censored times exceed \( t_i \) or whose censored times are equal to \( t_i \).

**Exact Likelihood**

\[
L_1(\beta) = \prod_{i=1}^{k} \left\{ \int_0^\infty \prod_{j \in D_i} \left[ 1 - \exp \left( - \sum_{l \in R_i^*} e^{\beta' Z_l(t_i)} \right) \right] \exp(-t) dt \right\}
\]

**Breslow Likelihood**

\[
L_2(\beta) = \prod_{i=1}^{k} \frac{e^{\beta' \sum_{j \in D_i} Z_j(t_i)}}{\left[ \sum_{l \in R_i} e^{\beta' Z_l(t_i)} \right]^{d_i}}
\]

Incorporating weights, the Breslow likelihood becomes

\[
L_2(\beta) = \prod_{i=1}^{k} \frac{e^{\beta' \sum_{j \in D_i} w_j Z_j(t_i)}}{\left[ \sum_{l \in R_i} w_l e^{\beta' Z_l(t_i)} \right]^{d_i}}
\]
Efron Likelihood

\[ L_3(\beta) = \prod_{i=1}^{k} \left( \prod_{j=1}^{d_i} \frac{e^{\beta' \sum_{j \in D_i} Z_j(t_i)}}{\left( \sum_{l \in R_i} e^{\theta' l(t_i)} - \frac{j-1}{d_i} \sum_{l \in D_i} e^{\theta' l(t_i)} \right) \prod_{j=1}^{d_i} w_j^{\sum_{l \in R_i} w_l e^{\theta' l(t_i)}}} \right) \]

Incorporating weights, the Efron likelihood becomes

\[ L_3(\beta) = \prod_{i=1}^{k} \left( \prod_{j=1}^{d_i} \frac{e^{\beta' \sum_{j \in D_i} Z_j(t_i)}}{\left( \sum_{l \in R_i} w_l e^{\theta' l(t_i)} - \frac{j-1}{d_i} \sum_{l \in D_i} w_l e^{\theta' l(t_i)} \right) \prod_{j=1}^{d_i} w_j} \right) \]

Discrete Time Scale

Let \( Q_i \) denote the set of all subsets of \( d_i \) individuals from the risk set \( R_i \). For each \( q \in Q_i \), \( q \) is a \( d_i \)-tuple \( (q_1, q_2, \ldots, q_{d_i}) \) of individuals who might have failed at \( t_i \).

Discrete Logistic Likelihood

\[ L_4(\beta) = \prod_{i=1}^{k} \left( \sum_{q \in Q_i} e^{\beta' \sum_{j \in D_i} Z_j(t_i)} \right) \]

The computation of \( L_4(\beta) \) and its derivatives is based on an adaptation of the recurrence algorithm of Gail et al. (1981) to the logarithmic scale. When there are no ties on the event times (that is, \( d_i = 1 \)), all four likelihood functions \( L_1(\beta), L_2(\beta), L_3(\beta), \) and \( L_4(\beta) \) reduce to the same expression. In a stratified analysis, the partial likelihood is the product of the partial likelihood functions for the individual strata.

Counting Process Style of Input

In the counting process formulation, data for each subject are identified by a triple \( \{N, Y, Z\} \) of counting, at risk, and covariate processes. Here, \( N(t) \) indicates the number of events that the subject experiences over the time interval \((0, t] \); \( Y(t) \) indicates whether the subject is at risk at time \( t \) (one if at risk and zero otherwise); and \( Z(t) \) is a vector of explanatory variables for the subject at time \( t \). The sample path of \( N \) is a step function with jumps of size +1 at the event times, and \( N(0) = 0 \). Unless \( Z(t) \) changes continuously with time, the data for each subject can be represented by multiple observations, each identifying a semiclosed time interval \((t_1, t_2]\), the values of the explanatory variables over that interval, and the event status at \( t_2 \). The subject remains at risk during the interval \((t_1, t_2]\), and an event may occur at \( t_2 \). Values of the explanatory variables for the subject remain unchanged in the interval. This style of data input was originated by Terry M. Therneau (1994).
For example, a patient has a tumor recurrence at weeks 3, 10, and 15 and is followed to week 23. The explanatory variables are Trt (treatment), \(Z_1\) (initial tumor number), and \(Z_2\) (initial tumor size), and, for this patient, the values of Trt, \(Z_1\), and \(Z_2\) are (1,1,3). The data for this patient are represented by the following four observations:

<table>
<thead>
<tr>
<th>T1</th>
<th>T2</th>
<th>Event</th>
<th>Trt</th>
<th>(Z_1)</th>
<th>(Z_2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>10</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>10</td>
<td>15</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>15</td>
<td>23</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

Here \((T_1,T_2)\) contains the at-risk intervals. The variable \(\text{Event}\) is a censoring variable indicating whether a recurrence has occurred at \(T_2\); a value of 1 indicates a tumor recurrence, and a value of 0 indicates nonrecurrence. The PHREG procedure fits the multiplicative hazards model, which is specified as follows:

```
proc phreg;
  model (T1,T2) * Event(0) = Trt Z1 Z2;
run;
```

Another useful application of the counting process formulation is delayed entry of subjects into the risk set. For example, in studying the mortality of workers exposed to a carcinogen, the survival time is chosen to be the worker’s age at death by malignant neoplasm. Any worker joining the workplace at a later age than a given event failure time is not included in the corresponding risk set. The variables of a worker consist of \(\text{Entry}\) (age at which the worker entered the workplace), \(\text{Age}\) (age at death or age censored), \(\text{Status}\) (an indicator of whether the observation time is censored, with the value 0 identifying a censored time), and \(X_1\) and \(X_2\) (explanatory variables thought to be related to survival). The specification for such an application is as follows.

```
proc phreg;
  model (Entry, Age) * Status(0) = X1 X2;
run;
```

Alternatively, you can use a time-dependent variable to control the risk set, as illustrated in the following specification:

```
proc phreg;
  model Age * Status(0) = X1 X2;
  if Age < Entry then X1= .;
run;
```

Here, \(X_1\) becomes a time-dependent variable. At a given death time \(t\), the value of \(X_1\) is reevaluated for each subject with \(\text{Age} \geq t\); subjects with \(\text{Entry} > t\) are given a missing value in \(X_1\) and are subsequently removed from the risk set. Computationally, this approach is not as efficient as the one that uses the counting process formulation.
The Multiplicative Hazards Model

Consider a set of \( n \) subjects such that the counting process \( N_i = \{N_i(t), t \geq 0\} \) for the \( i \)th subject represents the number of observed events experienced over time \( t \). The sample paths of the process \( N_i \) are step functions with jumps of size +1, with \( N_i(0) = 0 \). Let \( \beta \) denote the vector of unknown regression coefficients. The multiplicative hazards function \( \Lambda(t, Z_i(t)) \) for \( N_i \) is given by

\[
Y_i(t) d\Lambda(t, Z_i(t)) = Y_i(t) \exp(\beta' Z_i(t)) d\Lambda_0(t)
\]

where

- \( Y_i(t) \) indicates whether the \( i \)th subject is at risk at time \( t \) (specifically, \( Y_i(t) = 1 \) if at risk and \( Y_i(t) = 0 \) otherwise)
- \( Z_i(t) \) is the vector of explanatory variables for the \( i \)th subject at time \( t \)
- \( \Lambda_0(t) \) is an unspecified baseline hazard function

Refer to Fleming and Harrington (1991) and Andersen et al. (1992). The Cox model is a special case of this multiplicative hazards model, where \( Y_i(t) = 1 \) until the first event or censoring, and \( Y_i(t) = 0 \) thereafter.

The partial likelihood for \( n \) independent triplets \( (N_i, Y_i, Z_i), i = 1, \ldots, n \), has the form

\[
L(\beta) = \prod_{i=1}^{n} \prod_{t \geq 0} \left\{ \frac{Y_i(t) \exp(\beta' Z_i(t))}{\sum_{j=1}^{n} Y_j(t) \exp(\beta' Z_j(t))} \right\}^{\Delta N_i(t)}
\]

where \( \Delta N_i(t) = 1 \) if \( N_i(t) - N_i(t-) = 1 \), and \( \Delta N_i(t) = 0 \) otherwise.

Proportional Rates/Means Models for Recurrent Events

Let \( N(t) \) be the number of events experienced by a subject over the time interval \((0, t]\). Let \( dN(t) \) be the increment of the counting process \( N \) over \([t, t+dt)\). The rate function is given by

\[
d\mu_Z(t) = E[dN(t)|Z(t)] = e^{\beta' Z(t)} d\mu_0(t)
\]

where \( \mu_0(.) \) is an unknown continuous function. If the \( Z \) are time-independent, the rate model is reduced to the mean model

\[
\mu_Z(t) = e^{\beta' Z} \mu_0(t)
\]

The partial likelihood for \( n \) independent triplets \( (N_i, Y_i, Z_i), i = 1, \ldots, n \), of counting, at-risk, and covariate processes is the same as that of the multiplicative hazards model. However, a robust sandwich estimate is used for the covariance matrix of the parameter estimator instead of the model-based estimate.
Let $T_{ki}$ be the $k$th event time of the $i$th subject. Let $C_i$ be the censoring time of the $i$th subject. The at-risk indicator and the failure indicator are, respectively,

$$Y_i(t) = I(C_i \geq t) \quad \text{and} \quad \Delta_{ki} = I(T_{ki} \leq C_i)$$

Denote

$$S(t; \beta, t) = \sum_{i=1}^{n} Y_i(t)e^{\beta'Z_i(t)} \quad \text{and} \quad \bar{Z}(\beta, t) = \frac{\sum_{i=1}^{n} Y_i(t)e^{\beta'Z_i(t)}Z_i(t)}{S^{(0)}(\beta, t)}$$

Let $\hat{\beta}$ be the maximum likelihood estimate of $\beta$ and let $I(\hat{\beta})$ be the observed information matrix. The robust sandwich covariance matrix estimate is given by

$$I^{-1}(\hat{\beta}) \sum_{i=1}^{n} \left[ W_i(\hat{\beta})W_i'(\hat{\beta}) \right] I^{-1}(\hat{\beta})$$

where

$$W_i(\beta) = \sum_k \Delta_{ki} \left\{ Z_i(T_{ki}) - \bar{Z}(\beta, T_{ki}) \right\} - \sum_{i=1}^{n} \sum_l \Delta_{lj} Y_i(T_{lj})e^{\beta'Z_i(T_{lj})} \left\{ \frac{Z_i(T_{lj}) - \bar{Z}(\beta, T_{lj})}{S^{(0)}(\beta, T_{lj})} \right\}$$

For a given realization of the covariates $\xi$, the Nelson estimator is used to predict the mean function

$$\hat{\mu}_\xi(t) = e^{\hat{\beta}'\xi} \sum_{i=1}^{n} \sum_k I(T_{ki} \leq t) \Delta_{ki}$$

with standard error estimate given by

$$\hat{\sigma}^2(\hat{\mu}_\xi(t)) = \sum_{i=1}^{n} \left( \frac{1}{n} \hat{\Psi}_i(t, \xi) \right)^2$$

where

$$\frac{1}{n} \hat{\Psi}_i(\xi, t) = e^{\hat{\beta}'\xi} \left\{ \sum_k \frac{I(T_{ki} \leq t) \Delta_{ik}}{S^{(0)}(\hat{\beta}, T_{ki})} - \sum_{j=1}^{n} \sum_k \frac{Y_i(T_{kj})e^{\hat{\beta}'Z_i(T_{kj})}I(T_{kj} \leq t) \Delta_{kj}}{[S^{(0)}(\hat{\beta}, T_{kj})]^2} \right\}$$

$$\left[ \sum_{i=1}^{n} \sum_k I(T_{ki} \leq t) \Delta_{ik} [Z(\hat{\beta}, T_{ki}) - \xi] S^{(0)}(\hat{\beta}, T_{ki}) \right]^{-1}$$

$$\times I^{-1}(\hat{\beta}) \int_0^T \left[ Z_i(u) - \bar{Z}(\hat{\beta}, u) \right] d\hat{M}_i(u)$$
Since the cumulative mean function is always nonnegative, the log transform is used to compute confidence intervals. The 100(1 − α)% pointwise confidence limits for \( \mu_\xi(t) \) are

\[
\hat{\mu}_\xi(t) e^{\pm \frac{z_{\alpha/2}}{\hat{\sigma}(\hat{\mu}_\xi(t))}}
\]

where \( z_{\alpha/2} \) is the upper 100\( \alpha/2 \) percentage point of the standard normal distribution.

**Newton-Raphson Method**

Let \( L(\beta) \) be one of the likelihood functions described in the previous subsections. Let \( l(\beta) = \log L(\beta) \). Finding \( \beta \) such that \( L(\beta) \) is maximized is equivalent to finding the solution \( \hat{\beta} \) to the likelihood equations

\[
\frac{\partial l(\beta)}{\partial \beta} = 0
\]

With \( \hat{\beta}^0 = 0 \) as the initial solution, the iterative scheme is expressed as

\[
\hat{\beta}^{j+1} = \hat{\beta}^j - \left[ \frac{\partial^2 l(\hat{\beta}^j)}{\partial \beta^2} \right]^{-1} \frac{\partial l(\hat{\beta}^j)}{\partial \beta}
\]

The term after the minus sign is the Newton-Raphson step. If the likelihood function evaluated at \( \hat{\beta}^{j+1} \) is less than that evaluated at \( \hat{\beta}^j \), then \( \hat{\beta}^{j+1} \) is recomputed using half the step size. The iterative scheme continues until convergence is obtained, that is, until \( \hat{\beta}^{j+1} \) is sufficiently close to \( \hat{\beta}^j \). Then the maximum likelihood estimate of \( \beta \) is \( \hat{\beta} = \hat{\beta}^{j+1} \).

The model-based variance estimate of \( \hat{\beta} \) is obtained by inverting the information matrix \( I(\hat{\beta}) \)

\[
\hat{V}_n(\hat{\beta}) = I^{-1}(\hat{\beta}) = - \left[ \frac{\partial^2 l(\hat{\beta})}{\partial \beta^2} \right]^{-1}
\]
Let \( \bar{Z}(\beta, t) = \frac{S(1)(\beta, t)}{S(0)(\beta, t)} \). The score residual for the \( i \)th individual is
\[
u_i(\beta) = \Delta_i \left\{ Z_i(X_i) - \bar{Z}(\beta, X_i) \right\} - \sum_{j=1}^{n} \Delta_j \frac{w_j Y_j(X_j) e^{\beta'Z_j(X_j)}}{S(0)(\beta, X_j)} \left\{ Z_i(X_j) - \bar{Z}(\beta, X_j) \right\}
\]

The robust sandwich variance estimate of \( \hat{\beta} \) derived by Binder (1992) who incorporated weights into the analysis is
\[
\hat{V}_s(\hat{\beta}) = I^{-1}(\hat{\beta}) \left[ \sum_{j=1}^{n} (w_j \nu_j(\hat{\beta})) \otimes \right] I^{-1}(\hat{\beta})
\]
where \( I(\hat{\beta}) \) is the observed information matrix, and \( a \otimes = aa' \). Note that when \( w_i \equiv 1 \),
\[
\hat{V}_s(\hat{\beta}) = D'D
\]
where \( D \) is the matrix of DFBETAS residuals. This robust variance estimate was proposed by Lin and Wei (1989) and Reid and Crèpeau (1985).

**Testing the Global Null Hypothesis**

The following three likelihood statistics can be used to test the global null hypothesis \( H_0: \beta = 0 \). Under mild assumptions, each statistic has an asymptotic chi-square distribution with \( p \) degrees of freedom given the null hypothesis. The value \( p \) is the dimension of \( \beta \).

**Likelihood Ratio Test**
\[
\chi^2_{LR} = 2 \left[ l(\hat{\beta}) - l(0) \right]
\]
This formulation of the likelihood ratio test is not appropriate for the COVS option.

**Wald’s Test**
\[
\chi^2_W = \hat{\beta}' \left[ \hat{V}(\hat{\beta}) \right]^{-1} \hat{\beta}
\]
where \( \hat{V}(\hat{\beta}) = \hat{V}_m(\hat{\beta}) \) for the model-based variance estimate and \( \hat{V}(\hat{\beta}) = \hat{V}_s(\hat{\beta}) \) for the robust sandwich variance estimate.

**Score Test**
\[
\chi^2_S = \left[ \frac{\partial l(0)}{\partial \beta} \right]' \left[ I^{-1}(0) \right] \left[ \frac{\partial l(0)}{\partial \beta} \right]
\]
where \( I(0) = -\frac{\partial^2 l(0)}{\partial \beta^2} \). Replacing \( I^{-1}(0) \) by the robust sandwich variance estimate \( \hat{V}_s(0) \), the modified score test is also printed when the COVS option is specified.
Hazards Ratio Estimates and Confidence Limits

Let $\beta_i$ and $\hat{\beta}_i$ denote the $i$th component of $\beta$ and $\hat{\beta}$, respectively. The hazards ratio (also known as risk ratio) for the explanatory variable with regression coefficient $\beta_i$ is defined as $\exp(\beta_i)$. The hazards ratio is estimated by $\exp(\hat{\beta}_i)$. The $100(1 - \alpha)$% confidence limits for the hazards ratio are calculated as

$$\exp\left(\hat{\beta}_i \pm z_{\alpha/2} \sqrt{\hat{V}_{ii}(\hat{\beta})}\right)$$

where $\hat{V}_{ii}(\hat{\beta})$ is the $i$th diagonal element of the estimated covariance matrix $\hat{V}(\hat{\beta})$, and $z_{\alpha/2}$ is the 100$(1 - \alpha/2)$ percentile point of the standard normal distribution. The hazards ratio is the ratio of the hazards functions that correspond to a change of one unit of the given variable and conditional on fixed values of all other variables.

Testing Linear Hypotheses about Regression Coefficients

Linear hypotheses for $\beta$ are expressed in matrix form as

$$H_0: L\beta = c$$

where $L$ is a matrix of coefficients for the linear hypotheses, and $c$ is a vector of constants. The Wald chi-square statistic for testing $H_0$ is computed as

$$\chi^2_W = \left(L\hat{\beta} - c\right) \left[ L\hat{V}(\hat{\beta})L' \right]^{-1} \left(L\hat{\beta} - c\right)$$

where $\hat{V}(\hat{\beta})$ is the estimated covariance matrix. Under $H_0$, $\chi^2_W$ has an asymptotic chi-square distribution with $r$ degrees of freedom, where $r$ is the rank of $L$.

Analysis of Multivariate Failure Time Data

Multivariate failure time data arise when each study subject can potentially experience several events (for instance, multiple infections after surgery) or when there exists some natural or artificial clustering of subjects (for instance, a litter of mice) that induces dependence among the failure times of the same cluster. Data in the former situation are referred to as multiple events data, and data in the latter situation are referred to as clustered data. The multiple events data can be further classified into ordered and unordered data. For ordered data, there is a natural ordering of the multiple failures within a subject, which includes recurrent events data as a special case. For unordered data, the multiple event times result from several concurrent failure processes.

Multiple events data can be analyzed by the Wei, Lin, and Weissfeld (1989), aka WLW, method based on the marginal Cox models. For the special case of recurrent events data, you can fit the intensity model (Andersen and Gill 1982), the proportional rates/means model (Pepe and Cai 1993; Lawless and Nadeau 1995; Lin, Wei, Yang,
and Ying 2000), or the stratified models for total time and gap time proposed by Prentice, Williams, and Peterson (1981), aka PWP. For clustered data, you can carry out the analysis of Lee, Wei, and Amato (1992) based on the marginal Cox model. To use PROC PHREG to perform these analyses correctly and effectively, you have to array your data in a specific way to produce the correct risk sets.

All examples described in this section can be found in the program phrmult.sas in the SAS/STAT sample library. Furthermore, the “Examples” section in this chapter contains two examples to illustrate the methods for analyzing recurrent events data and clustered data.

**Marginal Cox Models for Multiple Events Data**

Suppose there are \( n \) subjects and each subject can experience up to \( K \) potential events. Let \( Z_{ki}(t) \) be the covariate process associated with the \( k \)th event for the \( i \)th subject. The marginal Cox models are given by

\[
\lambda_k(t; Z_{ki}) = \lambda_{k0}(t) e^{\beta_k' Z_{ki}(t)}, \quad k = 1, \ldots, K; \ i = 1, \ldots, n
\]

where \( \lambda_{k0}(t) \) is the (event-specific) baseline hazard function for the \( k \)th event and \( \beta_k \) is the (event-specific) column vector of regression coefficients for the \( k \)th event. WLW estimates \( \beta_1, \ldots, \beta_K \) by the maximum partial likelihood estimates \( \hat{\beta}_1, \ldots, \hat{\beta}_K \), respectively, and uses a robust sandwich covariance matrix estimate for \( (\hat{\beta}_1', \ldots, \hat{\beta}_K')' \) to account for the dependence of the multiple failure times.

By using a properly prepared input data set, you can estimate the regression parameters for all the marginal Cox models and compute the robust sandwich covariance estimates in one PROC PHREG invocation. For convenience of discussion, suppose each subject can potentially experience \( K = 3 \) events and there are two explanatory variables \( Z_1 \) and \( Z_2 \). The event-specific parameters to be estimated are \( \beta_1 = (\beta_{11}, \beta_{21})' \) for the first marginal model, \( \beta_2 = (\beta_{12}, \beta_{22})' \) for the second marginal model, and \( \beta_3 = (\beta_{13}, \beta_{23})' \) for the third marginal model. Inference of these parameters is based on the robust sandwich covariance matrix estimate of the parameter estimators. It is necessary that each row of the input data set represents the data for a potential event of a subject. The input data set should contain

- an ID variable for identifying the subject so that all observations of the same subject have the same ID value
- an Enum variable to index the multiple events. For example, Enum=1 for the first event, Enum=2 for the second event, and so on.
- a Time variable to represent the observed time from some time origin for the event. For recurrence events data, it is the time from the study entry to each recurrence.
- a Status variable to indicate whether the Time value is a censored or uncensored time. For example, Status=1 indicates an uncensored time and Status=0 indicates a censored time.
- independent variables (\( Z_1 \) and \( Z_2 \)).
The WLW analysis can be carried out by specifying

```plaintext
proc phreg covs(aggregate);
  model Time*Status(0)=Z11 Z12 Z13 Z21 Z22 Z23;
  strata Enum;
  id ID;
  Z11= Z1 * (Enum=1);
  Z12= Z1 * (Enum=2);
  Z13= Z1 * (Enum=3);
  Z21= Z2 * (Enum=1);
  Z22= Z2 * (Enum=2);
  Z23= Z2 * (Enum=3);
run;
```

Variable `Enum` is specified in the STRATA statement so that there is one marginal Cox model for each distinct value of `Enum`. Variables `Z11`, `Z12`, `Z13`, `Z21`, `Z22`, and `Z23` in the MODEL statement are event-specific variables derived from the independent variables `Z1` and `Z2` by the given programming statements. In particular, variables `Z11`, `Z12`, and `Z13` are the event-specific variables for the explanatory variable `Z1`; variables `Z21`, `Z22`, and `Z23` are event-specific variables for the explanatory variable `Z2`. For $j = 1, 2$, and $k = 1, 2, 3$, variable $Z_{jk}$ contains the same values as the explanatory variable $Z_j$ for the rows that correspond to $k$th marginal model and the value 0 for all other rows; as such, $\beta_{jk}$ is the regression coefficient for $Z_{jk}$. You can avoid using the programming statements in PROC PHREG by creating these event-specific variables in the input data set using the same programming statements in a DATA step.

The option COVS(AGGREGATE) is specified in the PROC statement to obtain the robust sandwich estimate of the covariance matrix, and the score residuals used in computing the middle part of the sandwich estimate are aggregated over identical ID values. You can also include TEST statements in the PROC PHREG code to test various linear hypotheses of the regression parameters based on the robust sandwich covariance matrix estimate.

Consider the AIDS study data in Wei, Lin, and Weissfeld (1989) from a randomized clinical trial to assess the antiretroviral capacity of ribavirin over times in AIDS patients. Blood sample were collected at weeks 4, 8, and 12 from each patients in three treatment groups (placebo, low dose of ribavirin, and high dose). For each serum sample, the failure time is the number of days before virus positivity was detected. If the sample was contaminated or it took a longer period of time than was achievable in the laboratory, the sample was censored. For example,

- Patient #1 in the placebo group has uncensored times 9, 6, and 7 days (that is, it took 9 days to detect viral positivity in the first blood sample, 6 days for the second blood sample, and 7 days for the third blood sample).
- Patient #14 in the low dose group of ribavirin has uncensored times of 16 and 17 days for the first and second sample, respectively, and a censored time of 21 days for the third blood sample.
Patient #28 in the High dose group has an uncensored time of 21 days for the first sample, no measurement for the second blood sample, and a censored time of 25 days for the third sample.

For a full-rank parameterization, two design variables are sufficient to represent three treatment groups. Based on the reference coding with placebo as the reference, the values of the two dummy explanatory variables Z1 and Z2 representing the treatments are:

<table>
<thead>
<tr>
<th>Treatment Group</th>
<th>Z1</th>
<th>Z2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Placebo</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Low dose ribavirin</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>High dose ribavirin</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

The bulk of the task in using PROC PHREG to perform the WLW analysis lies in the preparation of the input data set. As discussed earlier, the input data set should contain the ID, Enum, Time, and Status variables, and event-specific independent variables Z11, Z12, Z13, Z21, Z22, and Z23. Data for the three patients described earlier are arrayed as follows:

<table>
<thead>
<tr>
<th>ID</th>
<th>Time</th>
<th>Status</th>
<th>Enum</th>
<th>Z1</th>
<th>Z2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>9</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>6</td>
<td>1</td>
<td>2</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>7</td>
<td>1</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>14</td>
<td>16</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>14</td>
<td>17</td>
<td>1</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>14</td>
<td>21</td>
<td>0</td>
<td>3</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>28</td>
<td>21</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>28</td>
<td>25</td>
<td>0</td>
<td>3</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

The first three rows are data for Patient #1 with event times at 9, 6, and 7 days, one row for each event. The next three rows are data for Patient #14, who has an uncensored time of 16 days for the first serum sample, an uncensored time of 17 days for the second sample, and a censored time of 21 days for the third sample. The last two rows are data for Patient #28 of the high dose group (Z1=0 and Z2=1). Since the patient did not have a second serum sample, there are only two rows of data.
To perform the WLW analysis, you specify

```plaintext
proc phreg covs(aggregate);
  model Time*Status(0)=Z11 Z12 Z13 Z21 Z22 Z23;
  strata Enum;
  id ID;
  Z11= Z1 * (Enum=1);
  Z12= Z1 * (Enum=2);
  Z13= Z1 * (Enum=3);
  Z21= Z2 * (Enum=1);
  Z22= Z2 * (Enum=2);
  Z23= Z2 * (Enum=3);
  EqualLowDose: test Z11=Z12, Z12=Z23;
  AverageLow: test Z11,Z12,Z13 / e average;
run;
```

Two linear hypotheses are tested using the TEST statements. The specification

```
EqualLowDose: test Z11=Z12, Z12=Z13;
```

tests the null hypothesis $\beta_{11} = \beta_{12} = \beta_{13}$ of identical low-dose effects across three marginal models. The specification

```
AverageLow: test Z11,Z12,Z13 / e average;
```

tests the null hypothesis of no low-dose effects (that is, $\beta_{11} = \beta_{12} = \beta_{13} = 0$). The AVERAGE option computes the optimal weights for estimating the average low-dose effect $\beta_1^* = \beta_{11} = \beta_{12} = \beta_{13}$ and performs a 1 DF test for testing the null hypothesis that $\beta_1^* = 0$. The E option displays the coefficients for the linear hypotheses, including the optimal weights.

**Marginal Cox Models for Clustered Data**

Suppose there are $n$ clusters with $K_i$ members in the $i$th cluster, $i = 1, \ldots, n$. Let $Z_{ki}(t)$ be the covariate process associated with the $k$th member of the $i$th cluster. The marginal Cox model is given by

$$\lambda(t; Z_{ki}) = \lambda_0(t)e^{\beta'Z_{ki}(t)} \quad k = 1, \ldots, K_i; i = 1, \ldots, n$$

where $\lambda_0(t)$ is an arbitrary baseline hazard function and $\beta$ is the vector of regression coefficients. Lee, Wei, and Amato (1992) estimate $\beta$ by the maximum partial likelihood estimate $\hat{\beta}$ under the independent working assumption, and use a robust sandwich covariance estimate to account for the intracluster dependence.

To use PROC PHREG to analyze the clustered data, each member of a cluster is represented by an observation in the input data set. The input data set to PROC PHREG should contain

- an ID variable to identify the cluster so that members of the same cluster have the same ID value
• a *Time* variable to represent the observed survival time of a member of a cluster
• a *Status* variable to indicate whether the *Time* value is an uncensored or censored time. For example, Status=1 indicates an uncensored time and Status=0 indicates a censored time.
• the explanatory variables thought to be related to the failure time

Consider a tumor study in which one of three female rats of the same litter was randomly subjected to a drug treatment. The failure time is the time from randomization to the detection of tumor. If a rat died before the tumor was detected, the failure time was censored. For example,

• In litter #1, the drug-treated rat has an uncensored time of 101 days, one untreated rat has a censored time of 49 days, and the other untreated rat has a failure time of 104 days.
• In litter #3, the drug-treated rat has a censored time of 104 days, one untreated rat has a censored time of 102 days, and the other untreated rat has a censored time of 104 days.

In this example, a litter is a cluster and the rats of the same litter are members of the cluster. Let $T_{rt}$ be a 0-1 variable representing the treatment a rat received, with value 1 for drug treatment and 0 otherwise. Data for the two litters of rats described earlier contribute six observations to the input data set:

<table>
<thead>
<tr>
<th>Litter</th>
<th>Time</th>
<th>Status</th>
<th>$T_{rt}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>101</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>49</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>104</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>104</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>102</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>104</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The analysis of Lee, Wei, and Amato (1992) can be performed by PROC PHREG as follows:

```
proc phreg covs(aggregate);
  model Time*Status(0)=Treatment;
  id Litter;
run;
```

**Intensity and Rate/Mean Models for Recurrent Events Data**

Suppose each subject experiences recurrences of the same phenomenon. Let $N(t)$ be the number of events a subject experiences over the interval $[0,t]$ and let $Z(.)$ be the covariate process of the subject.
The intensity model (Andersen and Gill 1982) is given by
\[ \lambda_Z(t) dt = E\{dN(t) | F_t \} = \lambda_0(t) e^{\beta' Z(t)} dt \]

where \( F_t \) represents all the information of the processes \( N \) and \( Z \) up to time \( t \), \( \lambda_0(t) \) is an arbitrary baseline intensity function, and \( \beta \) is the vector of regression coefficients. This model consists of two components: 1) all the influence of the prior events on future recurrences, if there is any, is mediated through the time-dependent covariates, and 2) the covariates have multiplicative effects on the instantaneous rate of the counting process. If the covariates are time invariant, the risk of recurrences is unaffected by the past events.

The proportional rates and means models (Pepe and Cai 1993; Lawless and Nadeau 1995; Lin, Wei, Yang, and Ying 2000) assume that the covariates have multiplicative effects on the mean and rate functions of the counting process. The rate function is given by
\[ d\mu_Z(t) = E\{dN(t) | Z(t) \} = e^{\beta' Z(t)} d\mu_0(t) \]

where \( \mu_0(t) \) is an unknown continuous function and \( \beta \) is the vector of regression parameters. If \( Z \) is time invariant, the mean function is given by
\[ \mu_Z(t) = E\{N(t) | Z\} = e^{\beta' Z} \mu_0(t) \]

For both the intensity and the proportional rates/means models, estimates of the regression coefficients are obtained by solving the the partial likelihood score function. However, the covariance matrix estimate for the intensity model is computed as the inverse of the observed information matrix, while that for the proportional rates/means model is given by a sandwich estimate. For a given pattern of fixed covariates, the Nelson estimate for the cumulative intensity function is the same for the cumulative mean function, but their standard errors are not the same.

To fit the intensity or rate/mean model using PROC PHREG, the counting process style of input is needed. A subject with \( K \) events contributes \( K+1 \) observations to the input data set. The \( k \)th observation of the subject identifies the time interval from the \( (k-1) \)th event or time 0 (if \( k = 1 \)) to the \( k \)th event, \( k = 1, \ldots, K \). The \( (K+1) \)th observation represents the time interval from the \( K \)th event to time of censorship. The input data set should contain

- a \texttt{TStart} variable to represent the \( (k-1) \)th recurrence time or the value 0 if \( k = 1 \)
- a \texttt{TStop} variable to represent the \( k \)th recurrence time or the follow-up time if \( k = K + 1 \)
- a \texttt{Status} variable indicating whether the \texttt{TStop} time is a recurrence time or a censored time; for example, \texttt{Status}=1 for a recurrence time and \texttt{Status}=0 for censored time
- explanatory variables thought to be related to the recurrence times
If the rate/mean model is used, the input data should also contain an ID variable for identifying the subjects.

Consider the Chronic Granulomatous Disease (CGD) data listed in Fleming and Harrington (1991). The disease is a rare disorder characterized by recurrent pyrogenic infections. The study is a placebo-controlled randomized clinical trial conducted by the International CGD Cooperative Study to assess the effect of gamma interferon to reduce the rate of infection. For each study patient the times of recurrent infections along with a number of prognostic factors were collected. For example,

- Patient #17404, age 38, in the gamma interferon group had a follow-up time of 293 without any infection.
- Patient #204001, age 12, in the placebo group had an infection at 219 days, a recurrent infection at 373 days, and was followed up to 414 days.

Let $T_{rt}$ be the variable representing the treatment status with value 1 for gamma interferon and value 2 for placebo. Let Age be a covariate representing the age of the CGD patient. Data for the two CGD patients described earlier are given in the following table.

<table>
<thead>
<tr>
<th>ID</th>
<th>TStart</th>
<th>TStop</th>
<th>Status</th>
<th>Trt</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>174054</td>
<td>0</td>
<td>293</td>
<td>0</td>
<td>1</td>
<td>38</td>
</tr>
<tr>
<td>204001</td>
<td>0</td>
<td>219</td>
<td>1</td>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>204001</td>
<td>219</td>
<td>373</td>
<td>1</td>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>204001</td>
<td>373</td>
<td>414</td>
<td>0</td>
<td>2</td>
<td>12</td>
</tr>
</tbody>
</table>

Since Patient #174054 had no infection through the end of the follow-up period (293 days), there is only one observation representing the period from time 0 to the end of the follow-up. Data for Patient #204001 are broken into three observations, since there are two infections. The first observation represents the period from time 0 to the first infection, the second observation represents the period from the first infection to the second infection, and the third time period represents the period from the second infection to the end of the follow-up.

The following specification fits the intensity model.

```sas
proc phreg;
  model (TStart,TStop)*Status(0)=Trt Age;
run;
```

You can predict the cumulative intensity function for the a given pattern of fixed covariates by specifying the CUMHAZ= option in the BASELINE statement. Suppose you are interested in two fixed patterns, one for patients of age 30 in the gamma interferon group and the other for patients of age 1 in the placebo group. You first create the SAS data set as follows:
data Pattern;
  Trt=1; Age=30;
  output;
  Trt=2; Age=1;
  output;
run;

You then include the following BASELINE statement in the PROC PHREG specification. The CUMHAZ=_all_ option produces the cumulative hazard function estimates, the standard error estimates, and the lower and upper pointwise confidence limits.

baseline data=pattern out=out1 cumhaz=_all_ /nomean;

The following specification of PROC PHREG fits the mean model and predicts the cumulative mean function for the two patterns of covariates in the Pattern data set.

proc phreg covs(aggregate);
  model (Tstart,Tstop)*Status(0)=Trt Age;
  baseline data=Pattern out=out2 cmf=_all_ /nomean;
  id ID;

The COV(AGGREGATE) option computes the robust sandwich covariance matrix estimate. The CMF=_ALL_ option adds the cumulative mean function estimates, the standard error estimates, and the lower and upper pointwise confidence limits to the OUT=Out2 data set.

**PWP Models for Recurrent Events Data**

Let $N(t)$ be the number of events a subject experiences by time $t$. Let $Z(t)$ be the covariate vectors of the subject at time $t$. For a subject who has $K$ events before censorship takes place, let $t_0 = 0$, let $t_k$ be the $k$th recurrence time, $k = 1, \ldots, K$, and let $t_{k+1}$ be the censored time. Prentice, Williams, and Peterson (1981) consider two time scales, a total time from the beginning of the study and a gap time from immediately preceding failure. The PWP models are stratified Cox-type models that allow the shape of the hazard function to depend on the number of preceding events and possibly on other characteristics of \{ $N(t)$ and $Z(t)$ \}. The total time and gap time models are given, respectively, as follows:

$$
\lambda(t|F_{t-}) = \lambda_{0k}(t)e^{\beta_k'Z(t)}, \quad t_{k-1} < t \leq t_k
$$

$$
\lambda(t|F_{t-}) = \lambda_{0k}(t - t_{k-1})e^{\beta_k'Z(t)}, \quad t_{k-1} < t \leq t_k
$$

where $\lambda_{0k}$ is an arbitrary baseline intensity functions, and $\beta_k$ is a vector of stratum-specific regression coefficients. Here, a subject moves to the $k$th stratum immediately after his $(k-1)$th recurrence time and remains there until the $k$th recurrence occurs or until censorship takes place. For instance, a subject who experiences only one event moves from the first stratum to the second stratum after the event occurs and remains in the second stratum until the end of the follow-up.
You can use PROC PHREG to carry out the analyses of the PWP models, but you have to prepare the input data set to provide the correct risk sets. The input data set for analyzing the total time is the same as the AG model with an additional variable to represent the stratum that the subject is in. A subject with \( K \) events contributes \( K+1 \) observations to the input data set, one for each stratum that the subject moves to. The input data should contain

- a \( T_{\text{Start}} \) variable to represent the \((k-1)\)th recurrence time or the value 0 if \( k = 1 \)
- a \( T_{\text{Stop}} \) variable to represent the \( k \)th recurrence time or the time of censorship if \( k = K + 1 \)
- a \( \text{Status} \) variable with value 1 if the Time value is a recurrence time and value 0 if the Time value is a censored time
- an \( \text{Enum} \) variable representing the index of the stratum that the subject is in. For a subject who has only one event at \( t_1 \) and is followed to time \( t_c \), \( \text{Enum}=1 \) for the first observation (where \( \text{Time}=t_1 \) and \( \text{Status}=1 \)) and \( \text{Enum}=2 \) for the second observation (where \( \text{Time}=t_c \) and \( \text{Status}=0 \)).
- explanatory variables thought to be related to the recurrence times

To analyze gap times, the input data set should also include a \( \text{GapTime} \) variable which is equal to \( (T_{\text{Stop}} - T_{\text{Start}}) \).

Consider the data of two subjects in CGD data described in the previous section.

- Patients #174054, age 38, in the gamma interferon group had a follow-up time of 293 without any infection.
- Patient #204001, age 12, in the placebo group had an infection at 219 days, a recurrent infection at 373 days, and a follow-up time of 414 days.

To illustrate, suppose all subjects have at most two observed events. The data for the two subjects in the input data set are as follows:

<table>
<thead>
<tr>
<th>ID</th>
<th>( T_{\text{Start}} )</th>
<th>( T_{\text{Stop}} )</th>
<th>( \text{GapTime} )</th>
<th>( \text{Status} )</th>
<th>( \text{Enum} )</th>
<th>( \text{Trt} )</th>
<th>( \text{Age} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>174054</td>
<td>0</td>
<td>293</td>
<td>293</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>38</td>
</tr>
<tr>
<td>204001</td>
<td>0</td>
<td>219</td>
<td>219</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>204001</td>
<td>219</td>
<td>373</td>
<td>154</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>12</td>
</tr>
<tr>
<td>204001</td>
<td>373</td>
<td>414</td>
<td>41</td>
<td>0</td>
<td>3</td>
<td>2</td>
<td>12</td>
</tr>
</tbody>
</table>

Subject #174054 contributes only one observation to the input data, since there is no observed event. Subject #204001 contributes three observations, since there are two observed events.
To fit the total time model of PWP with stratum-specific slopes, you can either create the stratum-specific explanatory variables (Trt1, Trt2, and Trt3 for Trt, and Age1, Age2, and Age3 for Age) in a DATA step, or you can specify them in PROC PHREG using programming statements as follows:

```sas
proc phreg;
  model (TStart,TStop)*Status(0)=Trt1 Trt2 Trt3 Age1 Age2 Age3;
  strata Enum;
  Trt1= Trt * (Enum=1);
  Trt2= Trt * (Enum=2);
  Trt3= Trt * (Enum=3);
  Age1= Age * (Enum=1);
  Age2= Age * (Enum=2);
  Age3= Age * (Enum=3);
run;
```

To fit the total time model of PWP with the common regression coefficients, you specify

```sas
proc phreg;
  model (TStart,TStop)*Status(0)=Trt Age;
  strata Enum;
run;
```

To fit the gap time model of PWP with stratum-specific regression coefficients, you specify

```sas
proc phreg;
  model Gaptime*Status(0)=Trt1 Trt2 Trt3 Age1 Age2 Age3;
  strata Enum;
  Trt1= Trt * (Enum=1);
  Trt2= Trt * (Enum=2);
  Trt3= Trt * (Enum=3);
  Age1= Age * (Enum=1);
  Age2= Age * (Enum=2);
  Age3= Age * (Enum=3);
run;
```

To fit the gap time model of PWP with common regression coefficients, you specify

```sas
proc phreg;
  model Gaptime*Status(0)=Trt Age;
  strata Enum;
run;
```

The cumulative baseline hazard function $\Lambda_0$ is estimated by

$$\hat{\Lambda}_0(t) = \sum_{i=1}^{n} \int_0^t \frac{dN_i(s)}{\sum_{j=1}^{n} Y_j(s) \exp(\hat{\beta}'Z_j(s))}$$
Although this formula is for the BRESLOW=TIES option, the same formula is used for other TIES= options. The discrepancies between results obtained by using an appropriate formula for a nondefault TIES= option and those obtained by the given formula are minimal.

The martingale residual at \( t \) is defined as

\[
\hat{M}_i(t) = N_i(t) - \int_0^t Y_i(s) \exp(\hat{\beta}' Z_i(s)) d\hat{\Lambda}_0(s)
\]

Here \( \hat{M}_i(t) \) estimates the difference over \((0, t] \) between the observed number of events for the \( i \)th subject and a conditional expected number of events. The quantity \( \hat{M}_i(\infty) \) is referred to as the martingale residual for the \( i \)th subject. When the counting process MODEL specification is used, the RESMART= variable contains the component \((\hat{M}_i(t_2) - \hat{M}_i(t_1))\) instead of the martingale residual at \( t_2 \). The martingale residual for a subject can be obtained by summing up these component residuals within the subject. For the Cox model with no time-dependent explanatory variables, the martingale residual for the \( i \)th subject with observation time \( t_i \) and event status \( \delta_i \), where

\[
\delta_i = \begin{cases} 
0 & \text{if } t_i \text{ is a censored time} \\
1 & \text{if } t_i \text{ is an event time} 
\end{cases}
\]

is

\[
\hat{M}_i = \delta_i - \hat{\Lambda}_0(t_i) \exp(\hat{\beta}' z_i)
\]

The deviance residuals \( d_i \) are a transform of the martingale residuals:

\[
d_i = \text{sign}(\hat{M}_i) \sqrt{2 \left[ -\hat{M}_i - N_i(\infty) \log \left( \frac{N_i(\infty) - \hat{M}_i}{N_i(\infty)} \right) \right]}
\]

The square root shrinks large negative martingale residuals, while the logarithmic transformation expands martingale residuals that are close to unity. As such, the deviance residuals are more symmetrically distributed about zero than the martingale residuals. For the Cox model, the deviance residual reduces to the form

\[
d_i = \text{sign}(\hat{M}_i) \sqrt{2 \left[ -\hat{M}_i - \delta_i \log(\delta_i - \hat{M}_i) \right]}
\]

When the counting process MODEL specification is used, values of the RESDEV= variable are set to missing because the deviance residuals can be calculated on a per subject basis only.

The Schoenfeld (1982) residual vector is calculated on a per event time basis as

\[
U_i(t) = Z_i(t) - \bar{Z}(t)
\]
where \( t \) is an event time, and \( \bar{Z}(t) \) is a weighted average of the covariates over the risk set at time \( t \) and is given by

\[
\bar{Z}(t) = \frac{\sum_{l=1}^{n} Y_l(t) Z_l(t) \exp(\beta' Z_l(t))}{\sum_{l=1}^{n} Y_l(t) \exp(\beta' Z_l(t))}
\]

Under the proportional hazards assumption, the Schoenfeld residuals have the sample path of a random walk; therefore, they are useful in assessing time trend or lack of proportionality. Harrell (1986) proposed a \( z \)-transform of the Pearson correlation between these residuals and the rank order of the failure time as a test statistic for nonproportional hazards. Therneau, Grambsch, and Fleming (1990) considered a Kolmogorov-type test using the cumulative sum of the residuals.

The score process for the \( i \)th subject at time \( t \) is

\[
L_i(t) = \int_{0}^{t} [Z_i(s) - \bar{Z}(s)] d\hat{M}_i(s)
\]

The vector \( L_i \equiv L_i(\infty) \) is the score residual for the \( i \)th subject. When the counting process MODEL specification is used, the RESSCO= variables contain the components of \( (L_i(t_2) - L_i(t_1)) \) instead of the score process at \( t_2 \). The score residual for a subject can be obtained by summing up these component residuals within the subject.

The score residuals are a decomposition of the first partial derivative of the log likelihood. They are useful in assessing the influence of each subject on individual parameter estimates. They also play an important role in the computation of the robust sandwich variance estimators of Lin and Wei (1989) and Wei, Lin, and Weissfeld (1989).

**Diagnostics Based on Weighted Residuals**

The vector of weighted Schoenfeld residuals, \( r_i \), is computed as

\[
r_i = n_e \hat{V} U_i(t_i)
\]

where \( n_e \) is the total number of events, \( \hat{V} = \hat{V}(\hat{\beta}) \) is the estimated covariance matrix of \( \hat{\beta} \), and \( U_i(t_i) \) is the vector of Schoenfeld residuals at the event time \( t_i \). The components of \( r_i \) are output to the WTRESSCH= variables.

The weighted Schoenfeld residuals are useful in assessing the proportional hazards assumption. The idea is that most of the common alternatives to the proportional hazards can be cast in terms of a time-varying coefficient model

\[
\lambda(t, Z) = \lambda_0(t) \exp(\beta_1(t) Z_1 + \beta_2(t) Z_2 + \ldots)
\]

where \( \lambda(t, Z) \) and \( \lambda_0(t) \) are hazards rates. Let \( \hat{\beta}_j \) and \( r_{ij} \) be the \( j \)th component of \( \hat{\beta} \) and \( r_i \), respectively. Grambsch and Therneau (1994) suggest using a smoothed plot
of \((\hat{\beta}_j + r_{ij})\) versus \(t_i\) to discover the functional form of the time-varying coefficient \(\beta_j(t)\). A zero slope indicates that the coefficient is not varying with time.

The weighted score residuals are used more often than their unscaled counterparts in assessing local influence. Let \(\hat{\beta}_{(i)}\) be the estimate of \(\beta\) when the \(i\)th subject is left out, and let \(\Delta_i = \hat{\beta} - \hat{\beta}_{(i)}\). The \(j\)th component of \(\Delta_i\) can be used to assess any untoward effect of the \(i\)th subject on \(\hat{\beta}_j\). The exact computation of \(\Delta_i\) involves refitting the model each time a subject is omitted. Cain and Lange (1984) derived the following approximation of \(\Delta_i\) as weighted score residuals:

\[
\hat{\Delta}_i = \hat{V}L_i
\]

Here, \(\hat{V} = \hat{V}(\hat{\beta})\) is the estimated covariance matrix of \(\hat{\beta}\), and \(L_i\) is the vector of the score residuals for the \(i\)th subject. Values of \(\hat{\Delta}_i\) are output to the DFBETA= variables. Again, when the counting process MODEL specification is used, the DFBETA= variables contain the component \((\hat{V}L_i(t2) - \hat{V}L_i(t1))\). The vector \(\hat{\Delta}_i\) for a subject can be obtained by summing these components within the subject.

Note that these DFBETA statistics are a transform of the score residuals. In computing the robust sandwich variance estimators of Lin and Wei (1989) and Wei, Lin, and Weissfeld (1989), it is more convenient to use the DFBETA statistics than the score residuals (see Example 54.8 on page 3304).

### Influence of Observations on Overall Fit of the Model

The LD statistic approximates the likelihood displacement, which is the amount by which minus twice the log likelihood \((-2 \log L(\hat{\beta}))\), under a fitted model, changes when each subject in turn is left out. When the \(i\)th subject is omitted, the likelihood displacement is

\[
2 \log L(\hat{\beta}) - 2 \log L(\hat{\beta}_{(i)})
\]

where \(\hat{\beta}_{(i)}\) is the vector of parameter estimates obtained by fitting the model without the \(i\)th subject. Instead of refitting the model without the \(i\)th subject, Pettitt and Bin Daud (1989) propose that the likelihood displacement for the \(i\)th subject be approximated by

\[
LD_i = L'_i\hat{V}L_i
\]

This approximation is output to the LD= variable.

The LMAX statistic is another global influence statistic. This statistic is based on the symmetric matrix

\[
B = \hat{L}\hat{V}\hat{L}'
\]

where \(\hat{L}\) is the matrix with rows that are the score residual vectors \(L_i\). The elements of the eigenvector associated with the largest eigenvalue of the matrix \(B\), standardized to unit length, give a measure of the sensitivity of the fit of the model to each
observation in the data. The influence of the $i$th subject on the global fit of the model is proportional to the magnitude of $\zeta_i$, where $\zeta_i$ is the $i$th element of the vector $\zeta$ that satisfies

$$B\zeta = \lambda_{\text{max}} \zeta \quad \text{and} \quad \zeta' \zeta = 1$$

with $\lambda_{\text{max}}$ being the largest eigenvalue of $B$. The sign of $\zeta_i$ is irrelevant, and its absolute value is output to the LMAX= variable.

When the counting process MODEL specification is used, the LD= and LMAX= variables are set to missing, because these two global influence statistics can be calculated on a per subject basis only.

**Survival Distribution Estimates for the Cox Model**

Two estimators of the survivor function are available: one is the product-limit estimate and the other is based on the empirical cumulative hazard function.

**Product-Limit Estimates**

Let $C_i$ denote the set of individuals censored in the half-open interval $[t_i, t_{i+1})$, where $t_0 = 0$ and $t_{k+1} = \infty$. Let $\gamma_l$ denote the censoring times in $[t_i, t_{i+1})$; $l$ ranges over $C_i$. The likelihood function for all individuals is given by

$$L = \prod_{i=0}^{k} \left\{ \prod_{t \in D_i} \left( [S_0(t_i)] \exp(z_i' \beta) - [S_0(t_i + 0)] \exp(z_i' \beta) \right) \prod_{l \in C_i} [S_0(\gamma_l + 0)] \exp(z_i' \beta) \right\}$$

where $D_0$ is empty. The likelihood $L$ is maximized by taking $S_0(t) = S_0(t_i + 0)$ for $t_i < t \leq t_{i+1}$ and allowing the probability mass to fall only on the observed event times $t_1, \ldots, t_k$. By considering a discrete model with hazard contribution $1 - \alpha_i$ at $t_i$, you take $S_0(t_i) = S_0(t_{i-1} + 0) = \prod_{j=0}^{i-1} \alpha_j$, where $\alpha_0 = 1$. Substitution into the likelihood function produces

$$L = \prod_{i=0}^{k} \left\{ \prod_{j \in D_i} \left( 1 - \alpha_i \exp(z_i' \beta) \right) \prod_{l \in R_i - D_i} \alpha_i \exp(z_i' \beta) \right\}$$

If you replace $\beta$ with $\hat{\beta}$ estimated from the partial likelihood function and then maximize with respect to $\alpha_1, \ldots, \alpha_k$, the maximum likelihood estimate $\hat{\alpha}_i$ of $\alpha_i$ becomes a solution of

$$\sum_{j \in D_i} \frac{\exp(z_i' \hat{\beta})}{1 - \hat{\alpha}_i \exp(z_i' \hat{\beta})} = \sum_{l \in R_i} \exp(z_i' \hat{\beta})$$

When only a single failure occurs at $t_i$, $\hat{\alpha}_i$ can be found explicitly. Otherwise, an iterative solution is obtained by the Newton method.
The estimated baseline cumulative hazard function is
\[ \hat{H}_0(t) = -\log(\hat{S}_0(t)) \]
where \( \hat{S}_0(t) \) is the estimated baseline survivor function given by
\[ \hat{S}_0(t) = \hat{S}_0(t_{i-1} + 0) = \prod_{j=0}^{i-1} \hat{\alpha}_j, \quad t_{i-1} < t \leq t_i \]

For details, refer to Kalbfleisch and Prentice (1980). For a given realization of the explanatory variables \( \xi \), the product-limit estimate of the survival function at \( Z = \xi \) is
\[ \hat{S}(t, \xi) = [\hat{S}_0(t)]^{\exp(\beta' \xi)} \]

**Empirical Cumulative Hazards Function Estimates**

Let \( \xi \) be a given realization of the explanatory variables. The empirical cumulative hazard function estimate at \( Z = \xi \) is
\[ \hat{\Lambda}(t, \xi) = \sum_{i=1}^{n} \int_{0}^{t} \frac{dN_i(s)}{\sum_{j=1}^{n} Y_j(s) \exp(\beta' (z_j - \xi))} \]

The variance estimator of \( \hat{\Lambda}(t, \xi) \) is given by the following (Tsiatis 1981):
\[
\text{var}\{ n \hat{\Lambda}(t, \xi) \} = n \left\{ \sum_{i=1}^{n} \int_{0}^{t} \frac{dN_i(s)}{\sum_{j=1}^{n} Y_j(s) \exp(\beta' (z_j - \xi))} \right\}^2 + H'(t, \xi) \tilde{V}(\hat{\beta}) H(t, \xi)
\]
where \( \tilde{V}(\hat{\beta}) \) is the estimated covariance matrix of \( \hat{\beta} \) and
\[ H(t, \xi) = \sum_{i=1}^{n} \int_{0}^{t} \frac{n_{t} \sum_{l=1}^{n} Y_l(s) (z_l - \xi) \exp(\beta' (z_l - \xi)) dN_i(s)}{[\sum_{j=1}^{n} Y_j(s) \exp(\beta' (z_j - \xi))]^2} \]

The empirical cumulative hazard function (CH) estimate of the survivor function for \( Z = \xi \) is
\[ \hat{S}(t, \xi) = \exp(-\hat{\Lambda}(t, \xi)) \]
Confidence Intervals for the Survivor Function

Let $\hat{S}(t, \xi)$ and $\tilde{S}(t, \xi)$ correspond to the product-limit (PL) and empirical cumulative hazard function (CH) estimates of the survivor function for $Z = \xi$, respectively. Both the standard error of $\log(\hat{S}(t, \xi))$ and the standard error of $\log(\tilde{S}(t, \xi))$ are approximated by $\tilde{\sigma}_0(t, \xi)$, which is the square root of the variance estimate of $\hat{\Lambda}(t, \xi)$; refer to Kalbfleisch and Prentice (1980, p.116). By the delta method, the standard errors of $\hat{S}(t, \xi)$ and $\tilde{S}(t, \xi)$ are given by

$$\hat{\sigma}_1(t, \xi) = \hat{S}(t, \xi) \tilde{\sigma}_0(t, \xi)$$

$$\tilde{\sigma}_1(t, \xi) = \tilde{S}(t, \xi) \tilde{\sigma}_0(t, \xi)$$

respectively. The standard errors of $\log[-\log(\hat{S}(t, \xi))]$ and $\log[-\log(\tilde{S}(t, \xi))]$ are given by

$$\hat{\sigma}_2(t, \xi) = \frac{-\tilde{\sigma}_0(t, \xi)}{\log(\hat{S}(t, \xi))}$$

$$\tilde{\sigma}_2(t, \xi) = \frac{\tilde{\sigma}_0(t, \xi)}{\hat{\Lambda}(t, \xi)}$$

respectively.

Let $z_{\alpha/2}$ be the upper $100(1 - \alpha/2)$ percentile point of the standard normal distribution. A $100(1 - \alpha)$% confidence interval for the survivor function $S(t, \xi)$ is given in the following table.

<table>

</table>

Left Truncation of Failure Times

Left truncation arises when individuals only come under observation some known time after the natural time origin of the phenomenon under study. The risk set just prior to an event time does not include individuals whose left truncation times exceed the given event time. Thus, any contribution to the likelihood must be conditional on the truncation limit having been exceeded.

Although left truncation can be accommodated in PROC PHREG through the counting process style of input, such specification does not allow survival estimates to be output. Using the ENTRY= option in PROC PHREG for left truncation does not suppress computing the survival estimates.
Consider the following specifications of PROC PHREG:

```plaintext
proc phreg data=one;
  model t2*dead(0)=x1-x10/entry=t1;
  baseline out=out1 survival=s;
  title 'The ENTRY= option is Specified';
run;

proc phreg data=one;
  model (t1,t2)*dead(0)=x1-x10;
  baseline out=out2 survival=s;
  title 'Counting Process Style of Input';
run;
```

Both specifications yield the same model estimates; however, the baseline data set out2 is empty, since survivor function estimates are not computed when you use the counting process style of input.

### Variable Selection Methods

Five variable selection methods are available. The simplest method (and the default) is **SELECTION=NONE**, for which PROC PHREG fits the complete model as specified in the MODEL statement. The other four methods are **FORWARD** for forward selection, **BACKWARD** for backward elimination, **STEPWISE** for stepwise selection, and **SCORE** for best subsets selection. These methods are specified with the **SELECTION=** option in the MODEL statement. Intercept parameters are forced to stay in the model unless the **NOINT** option is specified.

When **SELECTION=FORWARD**, PROC PHREG first estimates parameters for variables forced into the model. These variables are the intercepts and the first \( n \) explanatory variables in the MODEL statement, where \( n \) is the number specified by the **START=** or **INCLUDE=** option in the MODEL statement (\( n \) is zero by default). Next, the procedure computes the adjusted chi-square statistics for each variable not in the model and examines the largest of these statistics. If it is significant at the **SLSENTRY=** level, the corresponding variable is added to the model. Once a variable is entered in the model, it is never removed from the model. The process is repeated until none of the remaining variables meet the specified level for entry or until the **STOP=** value is reached.

When **SELECTION=BACKWARD**, parameters for the complete model as specified in the MODEL statement are estimated unless the **START=** option is specified. In that case, only the parameters for the intercepts and the first \( n \) explanatory variables in the MODEL statement are estimated, where \( n \) is the number specified by the **START=** option. Results of the Wald test for individual parameters are examined. The least significant variable that does not meet the **SLSSTAY=** level for staying in the model is removed. Once a variable is removed from the model, it remains excluded. The process is repeated until no other variable in the model meets the specified level for removal or until the **STOP=** value is reached.
The SELECTION=STEPWISE option is similar to the SELECTION=FORWARD option except that variables already in the model do not necessarily remain. Variables are entered into and removed from the model in such a way that each forward selection step can be followed by one or more backward elimination steps. The stepwise selection process terminates if no further variable can be added to the model or if the variable just entered into the model is the only variable removed in the subsequent backward elimination.

For SELECTION=SCORE, PROC PHREG uses the branch and bound algorithm of Furnival and Wilson (1974) to find a specified number of models with the highest likelihood score (chi-square) statistic for all possible model sizes, from 1, 2, 3 variables, and so on, up to the single model containing all of the explanatory variables. The number of models displayed for each model size is controlled by the BEST= option. You can use the START= option to impose a minimum model size, and you can use the STOP= option to impose a maximum model size. For instance, with BEST=3, START=2, and STOP=5, the SCORE selection method displays the best three models (that is, the three models with the highest score chi-squares) containing 2, 3, 4, and 5 variables.

The SEQUENTIAL and STOPRES options can alter the default criteria for adding variables to or removing variables from the model when they are used with the FORWARD, BACKWARD, or STEPWISE selection methods.

### Assessment of the Proportional Hazards Model (Experimental)

The proportional hazards model specifies that the hazard function for the failure time \( T \) associated with a \( p \times 1 \) column covariate vector \( Z \) takes the form

\[
\lambda(t; Z) = \lambda_0(t)e^{\beta'Z}
\]

where \( \lambda_0(\cdot) \) is an unspecified baseline hazard function and \( \beta \) is a \( p \times 1 \) column vector of regression parameters. Lin et al. (1993) present graphical and numerical methods for model assessment based on the cumulative sums of martingale residuals and their transforms over certain coordinates (e.g., covariate values or follow-up times). The distributions of these stochastic processes under the assumed model can be approximated by the distributions of certain zero-mean Gaussian processes whose realizations can be generated by simulation. Each observed residual pattern can then be compared, both graphically and numerically, with a number of realizations from the null distribution. Such comparisons enable you to assess objectively whether the observed residual pattern reflects anything beyond random fluctuation. These procedures are useful in determining appropriate functional forms of covariates and assessing the proportional hazards assumption. You use the ASSESS statement to carry out these model-checking procedures.
For a sample of \( n \) subjects, let \((X_i, \Delta_i, Z_i)\) be the data of the \( i \)th subject; that is, \( X_i \) represents the observed failure time, \( \Delta_i \) has a value of 1 if \( X_i \) is an uncensored time and 0 otherwise, and \( Z_i = (Z_{i1}, \ldots, Z_{ip})' \) is a \( p \)-vector of covariates. Let \( N_i(t) = \Delta_i I(X_i \leq t) \) and \( Y_i(t) = I(X_i \geq t) \). Let

\[
S^{(0)}(\beta, t) = \sum_{i=1}^{n} Y_i(t) e^{\beta'Z_i} \quad \text{and} \quad Z(\beta, t) = \frac{\sum_{i=1}^{n} Y_i(t) e^{\beta'Z_i} Z_i}{S^{(0)}(\beta, t)}
\]

Let \( \hat{\beta} \) be the maximum partial likelihood estimate of \( \beta \), and let \( \mathcal{I}(\hat{\beta}) \) be the observed information matrix.

The martingale residuals are defined as

\[
\hat{M}_i(t) = N_i(t) - \int_0^t Y_i(u) e^{\hat{\beta}'Z_i} d\hat{\Lambda}_0(u), \quad i = 1, \ldots, n
\]

where \( \hat{\Lambda}_0(t) = \int_0^t \frac{\sum_{i=1}^{n} dN_i(u)}{S^{(0)}(\beta, u)} \).

The empirical score process \( U(\hat{\beta}, t) = (U_1(\hat{\beta}, t), \ldots, U_p(\hat{\beta}, t))' \) is a transform of the martingale residuals:

\[
U(\hat{\beta}, t) = \sum_{i=1}^{n} Z_i \hat{M}_i(t)
\]

**Checking the Functional Form of a Covariate**

To check the functional form of the \( j \)th covariate, consider the partial-sum process of \( \hat{M}_i = M_i(\infty) \):

\[
W_j(z) = \sum_{i=1}^{n} I(Z_{ij} \leq z) \hat{M}_i
\]

Under that null hypothesis that the model holds, \( W_j(z) \) can be approximated by the zero-mean gaussian process

\[
\hat{W}_j(z) = \sum_{l=1}^{n} \Delta_l \left\{ I(Z_{jl} \leq z) - \frac{\sum_{i=1}^{n} Y_i(t) e^{\beta'Z_i} I(Z_{ij} \leq z)}{S^{(0)}(\beta, X_l)} \right\} G_l - \sum_{k=1}^{n} \int_0^\infty Y_k(s) e^{\beta'Z_k} I(Z_{jk} \leq z) [Z_k - \hat{Z}(\hat{\beta}, s)]' d\hat{\Lambda}_0(s)
\times \mathcal{I}^{-1}(\hat{\beta}) \sum_{l=1}^{n} \Delta_l [Z_k - \hat{Z}(\hat{\beta}, X_l)] G_l
\]

where \( (G_1, \ldots, G_n) \) are independent standard normal variables that are independent of \((X_i, \Delta_i, Z_i), i = 1, \ldots, n\).
You can assess the functional form of the $j$th covariate by plotting a small number of realizations (the default is 20) of $\hat{W}_j(z)$ on the same graph as the observed $W_j(z)$ and visually comparing them to see how typical the observed pattern of $W_j(z)$ is of the null distribution samples. You can supplement the graphical inspection method with a Kolmogorov-type supremum test. Let $s_j$ be the observed value of $S_j = \sup_z |W_j(z)|$ and let $\hat{S}_j = \sup_z |\hat{W}_j(z)|$. The $p$-value $\Pr(S_j \geq s_j)$ is approximated by $\Pr(\hat{S}_j \geq \hat{s}_j)$, which in turn is approximated by generating a large number of realizations (1000 is the default) of $\hat{W}_j(.)$.

**Checking the Proportional Hazards Assumption**

Consider the standardized empirical score process for the $j$th component of $\mathbf{Z}$

$$U_j^*(t) = [I^{-1}(\hat{\beta})]^{\frac{1}{2}}U_j(\hat{\beta}, t),$$

Under the null hypothesis that the model holds, $U_j^*(t)$ can be approximated by

$$\hat{U}_j^*(t) = [I^{-1}(\hat{\beta})]^{\frac{1}{2}}\left\{ \sum_{l=1}^{n} I(X_l \leq t)\Delta_l [Z_{jl} - \bar{Z}_j(\hat{\beta}, t)]G_1 - \sum_{k=1}^{n} \int_0^t Y_k(s)e^{\hat{\beta}'Z_k[Z_k - \mathbf{Z}(\hat{\beta}, s)']d\hat{\Lambda}_0(s) - \times I^{-1}(\hat{\beta})\sum_{l=1}^{n} \Delta_l [\mathbf{Z}_l - \bar{\mathbf{Z}}(\hat{\beta}, X_l)]G_1 \right\}$$

where $\bar{Z}_j(\hat{\beta}, t)$ is the $j$th component of $\mathbf{Z}(\hat{\beta}, t)$, and $(G_1, \ldots, G_n)$ are independent standard normal variables that are independent of $(X_i, \Delta_i, \mathbf{Z}_i, (i = 1, \ldots, n))$.

You can assess the proportional hazards assumption for the $j$th covariate by plotting a few realizations of $\hat{U}_j^*(t)$ on the same graph as the observed $U_j^*(t)$ and visually comparing them to see how typical the observed pattern of $U_j^*(t)$ is of the null distribution samples. Again you can supplement the graphical inspection method with a Kolmogorov-type supremum test. Let $s_j^*$ be the observed value of $S_j^* = \sup_t |U_j^*(t)|$ and let $\hat{S}_j^* = \sup_t |\hat{U}_j^*(t)|$. The $p$-value $\Pr(S_j^* \geq s_j^*)$ is approximated by $\Pr(\hat{S}_j^* \geq \hat{s}_j^*)$, which in turn is approximated by generating a large number of realizations (1000 is the default) of $\hat{U}_j^*(.)$.

**Computational Resources**

Let $n$ be the number of observations in a BY group. Let $p$ be the number of explanatory variables. The minimum working space (in bytes) needed to process the BY group is

$$\max\{12n, 24p^2 + 160p\}$$
Extra memory is needed for certain TIES= options. Let $k$ be the maximum multiplicity of tied times. The TIES=DISCRETE option requires extra memory (in bytes) of

$$4k(p^2 + 4p)$$

The TIES=EXACT option requires extra memory (in bytes) of

$$24(k^2 + 5k)$$

If sufficient space is available, the input data are also kept in memory. Otherwise, the input data are reread from the utility file for each evaluation of the likelihood function and its derivatives, with the resulting execution time substantially increased.

**Displayed Output**

If you use the NOPRINT option in the PROC PHREG statement, the procedure does not display any output. Otherwise, the displayed output of the PHREG procedure includes the following:

- the “Model Information” table, which contains:
  - the two-level name of the input data set
  - the name and label of the failure time variable
  - if you specify the censoring variable,
    - the name and label of the censoring variable
    - the values that the censoring variable assumes to indicate censored times
  - if you use the OFFSET= option in the MODEL statement, the name and label of the offset variable
  - if you specify the FREQ statement, the name and label of the frequency variable
  - if you specify the WEIGHT statement, the name and label of the weight variable
  - the method of handling ties in the failure time
- the “Summary of the Number of Event and Censored Values” table, which displays, for each stratum, the breakdown of the number of events and censored values. This table is not produced if the NOSUMMARY option is specified.
- if you specify the SIMPLE option in the PROC PHREG statement, the “Simple Statistics for Explanatory Variables” table, which displays, for each stratum, the mean, standard deviation, and minimum and maximum for each explanatory variable in the MODEL statement
if you specify the ITPRINT option in the MODEL statement, the “Iteration History” table, which displays the iteration number, step size, log likelihood, and parameter estimates at each iteration. The last evaluation of the gradient vector is also displayed.

- the “Model Fit Statistics” table, which gives the values of \(-2\) log likelihood for fitting a model with no explanatory variable and for fitting a model with all the explanatory variables. The AIC and SBC are also given in this table.

- the “Testing Global Null Hypothesis: BETA=0” table, which displays results of the likelihood ratio test, the score test, and the Wald test.

- the “Analysis of Maximum Likelihood Estimates” table, which contains:
  - the maximum likelihood estimate of the parameter
  - the estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
  - if you specify the COVS option in the PROC statement, the ratio of the robust standard error estimate to the model-based standard error estimate
  - the Wald Chi-Square statistic, computed as the square of the parameter estimate divided by its standard error estimate
  - the degrees of freedom of the Wald chi-square statistic. It has a value of 1 unless the corresponding parameter is redundant or infinite, in which case the value is 0.
  - the \(p\)-value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom
  - the hazards ratio estimate computed by exponentiating the parameter estimate
  - if you specified the RISKLIMITS option in the MODEL statement, the confidence limits for the hazards ratio

if you specify SELECTION=SCORE in the MODEL statement, the “Regression Models Selected by Score Criterion” table, which gives the number of explanatory variables in each model, the score chi-square statistic, and the names of the variables included in the model.

if you use the FORWARD or STEPWISE selection method and you specify the DETAILS option in the MODEL statement, the “Analysis of Variables Not in the Model” table, which gives the Score chi-square statistic for testing the significance of each variable not in the model (after adjusting for the variables already in the model), and the \(p\)-value of the chi-square statistic with respect to a chi-square distribution with one degree of freedom. This table is produced before a variable is selected for entry in a forward selection step.

if you specify the FORWARD, BACKWARD, or STEPWISE selection method, a table summarizing the model-building process, which gives the step number, the explanatory variable entered or removed at each step, the chi-square statistic, and the corresponding \(p\)-value on which the entry or removal is based.
• if you use the COVB option in the MODEL statement, the estimated covariance matrix of the parameter estimates
• if you use the CORRB option in the MODEL statement, the estimated correlation matrix of the parameter estimates
• if you specify a TEST statement,
  – the “Linear Coefficients” table, which gives the coefficients and constants of the linear hypothesis (if the E option is specified)
  – the printing of the intermediate calculations of the Wald test (if the option PRINT is specified)
  – the “Test Results” table, which gives the Wald chi-square statistic, the degrees of freedom, and the p-value
  – the “Average Effect” table, which gives the weighted average of the parameter estimates for the variables in the TEST statement, the estimated standard error, the z-score, and the p-value (if the AVERAGE option is specified)

**ODS Table Names**

PROC PHREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**ODS Graphics (Experimental)**

This section describes the use of ODS for creating statistical graphs for model assessment with the PHREG procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs you must specify the ODS GRAPHICS statement in addition to the ASSESS statement in PROC PHREG. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

**ODS Graph Names**

PROC PHREG assigns a name to each graph it creates using the ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 54.2.

Examples

Example 54.1. Stepwise Regression

Krall, Uthoff, and Harley (1975) analyzed data from a study on multiple myeloma in which researchers treated 65 patients with alkylating agents. Of those patients, 48 died during the study and 17 survived. In the data set Myeloma, the variable Time represents the survival time in months from diagnosis. The variable VStatus consists of two values, 0 and 1, indicating whether the patient was alive or dead, respectively, at the end of the study. If the value of VStatus is 0, the corresponding value of Time is censored. The variables thought to be related to survival are LogBUN (log(BUN) at diagnosis), HGB (hemoglobin at diagnosis), Platelet (platelets at diagnosis: 0=abnormal, 1=normal), Age (age at diagnosis in years), LogWBC (log(WBC) at diagnosis), Frac (fractures at diagnosis: 0=none, 1=present), LogPBM (log percentage of plasma cells in bone marrow), Protein (proteinuria at diagnosis), and SCalc (serum calcium at diagnosis). Interest lies in identifying important prognostic factors from these nine explanatory variables.

Example 54.1. Stepwise Regression

The stepwise selection process consists of a series of alternating step-up and step-down phases. The former adds variables to the model, while the latter removes variables from the model.

Stepwise regression analysis is requested by specifying the SELECTION=STEPWISE option in the MODEL statement. The option SLENTRY=0.25 specifies that a variable has to be significant at the 0.25 level before it can be entered into the model, while the option SLSTAY=0.15 specifies that a variable in the model has to be significant at the 0.15 level for it to remain in the model. The DETAILS option requests detailed results for the variable selection process.

```r
proc phreg data=Myeloma;
   model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC Frac LogPBM Protein SCalc / selection=stepwise slentry=0.25 slstay=0.15 details;
run;
```
Results of the stepwise regression analysis are displayed in Output 54.1.1 through Output 54.1.7.

Individual score tests are used to determine which of the nine explanatory variables is first selected into the model. In this case, the score test for each variable is the global score test for the model containing that variable as the only explanatory variable. The chi-square statistic is compared to a chi-square distribution with one degree of freedom. **Output 54.1.1** displays the chi-square statistics and the corresponding p-values. The variable LogBUN has the largest chi-square value (8.5164), and it is significant (p = 0.0035) at the SLENTRY=0.25 level. The variable LogBUN is thus entered into the model. **Output 54.1.2** displays the model results. Since the Wald chi-square statistic is significant (p = 0.0039) at the SLSTAY=0.15 level, LogBUN stays in the model.
**Output 54.1.2.** First Model in the Stepwise Selection Process

**Step 1.** Variable LogBUN is entered. The model contains the following explanatory variables:

LogBUN

**Convergence Status**

Convergence criterion (GCONV=1E-8) satisfied.

<td>0.888</td>
</tr>
</tbody>
</table>

The next step consists of selecting another variable to add to the model. Output 54.1.3 displays the chi-square statistics and p-values of individual score tests (adjusted for LogBUN) for the remaining eight variables. The score chi-square for a given variable is the value of the likelihood score test for testing the significance of the variable in the presence of LogBUN. The variable HGB is selected because it has the highest chi-square value (4.3468), and it is significant (p = 0.0371) at the SLENTRY=0.25 level. Output 54.1.4 displays the fitted model containing both LogBUN and HGB. Based on the Wald statistics, neither LogBUN nor HGB is removed from the model.
Output 54.1.5. Third Model in the Stepwise Regression

Step 3. Variable SCalc is entered. The model contains the following explanatory variables:

LogBUN  HGB  SCalc

Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Model Fit Statistics

<table>
<thead>
<tr>
<th>Criterion</th>

<td>1</td>
<td>0.13286</td>
<td>0.09868</td>
<td>1.8127</td>
<td>0.1782</td>
<td>1.142</td>
</tr>
</tbody>
</table>

Output 54.1.5 shows Step 3 of the selection process, in which the variable SCalc is added, resulting in the model with LogBUN, HGB, and SCalc as the explanatory variables. Note that SCalc has the smallest Wald chi-square statistic, and it is not significant ($p = 0.1782$) at the SLSTAY=0.15 level. The variable SCalc is then removed from the model in a step-down phase in Step 4 (Output 54.1.6). The removal of SCalc brings the stepwise selection process to a stop in order to avoid repeatedly entering and removing the same variable.
Output 54.1.6. Final Model in the Stepwise Regression

Step 4. Variable SCalc is removed. The model contains the following explanatory variables:

LogBUN  HGB

Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Example 54.2. Best Subset Selection

An alternative to stepwise selection of variables is best subset selection. The procedure uses the branch and bound algorithm of Furnival and Wilson (1974) to find a specified number of best models containing one, two, three variables, and so on, up to the single model containing all of the explanatory variables. The criterion used to determine “best” is based on the global score chi-square statistic. For two models A and B, each having the same number of explanatory variables, model A is considered to be better than model B if the global score chi-square statistic for A exceeds that for B.

Best subset selection analysis is requested by specifying the SELECTION=SCORE option in the MODEL statement. The BEST=3 option requests the procedure to identify only the three best models for each size. In other words, PROC PHREG will list the three models having the highest score statistics of all the models possible for a given number of covariates.

```plaintext
proc phreg data=Myeloma;
  model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC Frac LogPBM Protein SCalc /
    selection=score best=3;
run;
```
Output 54.2.1 displays the results of this analysis. The number of explanatory variables in the model is given in the first column, and the names of the variables are listed on the right. The models are listed in descending order of their score chi-square values within each model size. For example, among all models containing two explanatory variables, the model that contains the variables LogBUN and HGB has the largest score value (12.7252), the model that contains the variables LogBUN and Platelet has the second largest score value (11.1842), and the model that contains the variables LogBUN and SCalc has the third largest score value (9.9962).

**Example 54.3. Conditional Logistic Regression for m:n Matching**

Conditional logistic regression is used to investigate the relationship between an outcome and a set of prognostic factors in matched case-control studies. The outcome is whether the subject is a case or a control. If there is only one case and one control, the matching is 1:1. The m:n matching refers to the situation in which there is a varying number of cases and controls in the matched sets. You can perform conditional
logistic regression with the PHREG procedure by using the discrete logistic model and forming a stratum for each matched set. In addition, you need to create dummy survival times so that all the cases in a matched set have the same event time value, and the corresponding controls are censored at later times.

Consider the following set of low infant birth-weight data extracted from Appendix 1 of Hosmer and Lemeshow (1989). These data represent 189 women, of whom 59 had low birth-weight babies and 130 had normal weight babies. Under investigation are the following risk factors: weight in pounds at the last menstrual period (LWT), presence of hypertension (HT), smoking status during pregnancy (Smoke), and presence of uterine irritability (UI). For HT, Smoke, and UI, a value of 1 indicates a “yes” and a value of 0 indicates a “no.” The woman’s age (Age) is used as the matching variable. The SAS data set LBW contains a subset of the data corresponding to women between the ages of 16 and 32.

```SAS
data LBW;
  input id Age Low LWT Smoke HT UI @@;
  Time=2-Low;
datalines;
25  16  1  130  0  0  0  143 16  0  110 0  0  0
166 16  0  112  0  0  0  167 16  0  135 1  0  0
189 16  0  135  1  0  0  206 16  0  170 0  0  0
216 16  0  95  0  0  0  37 17  1  130 1  0  1

Example 54.3. Conditional Logistic Regression for m:n Matching
The variable Low is used to determine whether the subject is a case (Low=1, low birth-weight baby) or a control (Low=0, normal weight baby). The dummy time variable Time takes the value 1 for cases and 2 for controls.
The following SAS statements produce a conditional logistic regression analysis of the data. The variable Time is the response, and Low is the censoring variable. Note that the data set is created so that all the cases have the same event time, and the controls have later censored times. The matching variable Age is used in the STRATA statement so each unique age value defines a stratum. The variables LWT, Smoke, HT, and UI are specified as explanatory variables. The TIES=DISCRETE option requests the discrete logistic model.

```sas
proc phreg data=LBW;
  model Time*Low(0)= LWT Smoke HT UI / ties=discrete;
  strata Age;
run;
```

The procedure displays a summary of the number of event and censored observations for each stratum. These are the number of cases and controls for each matched set shown in Output 54.3.1.

**Output 54.3.1. Summary of Number of Case and Controls**

---
Results of the conditional logistic regression analysis are shown in Output 54.3.2. Based on the Wald test for individual variables, the variables LWT, Smoke, and HT are statistically significant while UI is marginal.

The hazards ratios, computed by exponentiating the parameter estimates, are useful in interpreting the results of the analysis. If the hazards ratio of a prognostic factor is larger than 1, an increment in the factor increases the hazard rate. If the hazards ratio is less than 1, an increment in the factor decreases the hazard rate. Results indicate that women were more likely to have low birth-weight babies if they were underweight in the last menstrual cycle, were hypertensive, smoked during pregnancy, or suffered uterine irritability.

For matched case-control studies with one case per matched set (1:n matching), the likelihood function for the conditional logistic regression reduces to that of the Cox model for the continuous time scale. For this situation, you can use the default TIES=BRESLOW.
Example 54.4. Model Using Time-Dependent Explanatory Variables

Time-dependent variables can be used to model the effects of subjects transferring from one treatment group to another. One example of the need for such strategies is the Stanford heart transplant program. Patients are accepted if physicians judge them suitable for heart transplant. Then, when a donor becomes available, physicians choose transplant recipients according to various medical criteria. A patient’s status can be changed during the study from waiting for a transplant to being a transplant recipient. Transplant status can be defined by the time-dependent covariate function \( z = z(t) \) as

\[
z(t) = \begin{cases} 
0 & \text{if the patient has not received the transplant at time } t \\
1 & \text{if the patient has received the transplant at time } t 
\end{cases}
\]

The Stanford heart transplant data that appear in Crowley and Hu (1977) consist of 103 patients, 69 of whom received transplants. The data are saved in a SAS data set called Heart. For each patient in the program, there is a birth date (Bir_Date), a date of acceptance (Acc_Date), and a date last seen (Ter_Date). The survival time (Time) in days is defined as \( \text{Time} = \text{Ter}_\text{Date} - \text{Acc}_\text{Date} \). The survival time is said to be uncensored (Status=1) or censored (Status=0), depending on whether Ter_Date is the date of death or the closing date of the study. The age in years at acceptance into the program is \( \text{Acc}_\text{Age} = (\text{Acc}_\text{Date} - \text{Bir}_\text{Date}) / 365 \). Previous open-heart surgery for each patient is indicated by the variable PrevSurg. For each transplant recipient, there is a date of transplant (Xpl_Date) and three measures (NMismatch, Antigen, Mismatch) of tissue-type mismatching. The waiting period (WaitTime) in days for a transplant recipient is calculated as \( \text{WaitTime} = \text{Xpl}_\text{Date} - \text{Acc}_\text{Date} \), and the age in years at transplant is \( \text{Xpl}_\text{Age} = (\text{Xpl}_\text{Date} - \text{Bir}_\text{Date}) / 365 \). For those who do not receive heart transplants, the WaitTime, Xpl_Age, NMismatch, Antigen, and Mismatch variables contain missing values.

The input data contains dates that have a two-digit year representation. The SAS option YEARCUTOFF=1900 is specified to ensure that a two-digit year xx is year 19xx.
The code is as follows:

```plaintext
options yearcutoff=1900;

data Heart;
  input ID @5 Bir_Date mmddyy8.
         @14 Acc_Date mmddyy8.
         @23 Xpl_Date mmddyy8.

Crowley and Hu (1977) have presented a number of analyses to assess the effects of various explanatory variables on the survival of patients. This example fits two of the models that they have considered.

The first model consists of two explanatory variables—the transplant status and the age at acceptance. The transplant status ($X_{\text{Status}}$) is a time-dependent variable defined by the programming statements between the MODEL statement and the RUN statement. The $X_{\text{Status}}$ variable takes the value 1 or 0 at time $t$ (measured from the date of acceptance), depending on whether or not the patient has received a transplant at that time. Note that the value of $X_{\text{Status}}$ changes for subjects in each risk set (subjects still alive just before each distinct event time); therefore, the variable cannot be created in the DATA step. The variable $\text{Acc\_Age}$, which is not time-dependent, accounts for the possibility that pretransplant risks vary with age.

```
proc phreg data= Heart;
  model Time*Status(0)= XStatus Acc_Age;
  if (WaitTime = . or Time < WaitTime) then XStatus=0.;
  else XStatus= 1.0;
run;
```

Results of this analysis are shown in Output 54.4.1. Transplantation appears to be associated with a slight decrease in risk, although the effect is not significant ($p = 0.8432$). The age at acceptance as a pretransplant risk factor adds significantly to the model ($p = 0.0294$). The risk increases significantly with age at acceptance.

<td>0.0294</td>
<td>1.032</td>
</tr>
</tbody>
</table>
The second model consists of three explanatory variables—the transplant status, the transplant age, and the mismatch score. Four transplant recipients who were not typed have no Mismatch values; they are excluded from the analysis by the use of a WHERE clause. The transplant age (XAge) and the mismatch score (XScore) are also time-dependent and are defined in a fashion similar to that of XStatus. While the patient is waiting for a transplant, XAge and XScore have a value of 0. After the patient has migrated to the recipient population, XAge takes on the value of Xpl_Age (transplant age for the recipient), and XScore takes on the value of Mismatch (a measure of the degree of dissimilarity between donor and recipient).

```
proc phreg data= Heart;
  model Time*Status(0) = XStatus XAge XScore;
  where NotTyped ^= 'y';
  if (WaitTime = . or Time < WaitTime) then do;
    XStatus=0.;
    XAge=0.;
    XScore= 0.;
  end;
  else do;
    XStatus= 1.0;
    XAge= Xpl_Age;
    XScore= Mismatch;
  end;
run;
```

Results of the analysis are shown in Output 54.4.2. Note that only 99 patients are included in this analysis, instead of 103 patients as in the previous analysis, since four transplant recipients who were not typed are excluded. The variable XAge is statistically significant ($p = 0.0146$) with a hazards ratio exceeding 1. Therefore, patients who had a transplant at younger ages lived longer than those who received a transplant later in their lives. The variable XScore has only minimal effect on the survival ($p = 0.1129$).

**Example 54.5. Time-Dependent Repeated Measurements of a Covariate**

Repeated determinations may be made during the course of a study of variables thought to be related to survival. Consider an experiment to study the dosing effect of a tumor-promoting agent. Forty-five rodents initially exposed to a carcinogen were randomly assigned to three dose groups. After the first death of an animal, the rodents were examined every week for the number of papillomas. Investigators were interested in determining the effects of dose on the carcinoma incidence after...
adjusting for the number of papillomas.

The input data set TUMOR consists of the following 19 variables:

- **ID** (subject identification)
- **Time** (survival time of the subject)
- **Dead** (censoring status where 1=dead and 0=censored)
- **Dose** (dose of the tumor-promoting agent)
- **P1–P15** (number of papillomas at the 15 times that animals died. These 15 death times are weeks 27, 34, 37, 41, 43, 45, 46, 47, 49, 50, 51, 53, 65, 67, and 71. For instance, subject 1 died at week 47; it had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. For an animal that died before week 71, the number of papillomas is missing for those times beyond its death.)

The following SAS statements create the data set TUMOR:

```sas
data Tumor;
  infile datalines missover;
  input ID Time Dead Dose P1-P15;
  label ID='Subject ID';
  datalines;
1 47 1 1.0 0 5 6 8 10 10 10 10

28 49 1 2.5 2 3 3 3 4 4 4 4 4 4
```
The number of papillomas (NPap) for each animal in the study was measured repeatedly over time. One way of handling time-dependent repeated measurements in the PHREG procedure is to use programming statements to capture the appropriate covariate values of the subjects in each risk set. In this example, NPap is a time-dependent explanatory variable with values that are calculated by means of the programming statements shown in the following SAS statements:

```sas
proc phreg data=Tumor;
  model Time*Dead(0)=Dose NPap;
  array pp{*} P1-P14;
  array tt{*} t1-t15;
  t1 = 27;
  t2 = 34;
  t3 = 37;
  t4 = 41;
  t5 = 43;
  t6 = 45;
  t7 = 46;
  t8 = 47;
  t9 = 49;
  t10= 50;
  t11= 51;
  t12= 53;
  t13= 65;
  t14= 67;
  t15= 71;
  if Time < tt[1] then NPap=0;
  else if time >= tt[15] then NPap=P15;
  else do i=1 to dim(pp);
    if tt[i] <= Time < tt[i+1] then NPap= pp[i];
  end;
run;
```
At each death time, the NPap value of each subject in the risk set is recalculated to reflect the actual number of papillomas at the given death time. For instance, subject one in the data set Tumor was in the risk sets at weeks 27 and 34; at week 27, the animal had no papilloma, while at week 34, it had five papillomas. Results of the analysis are shown in Output 54.5.1.

After the number of papillomas is adjusted for, the dose effect of the tumor-promoting agent is not statistically significant.

Another way to handle time-dependent repeated measurements in the PHREG procedure is to use the counting process style of input. Multiple records are created for each subject, one record for each distinct pattern of the time-dependent measurements. Each record contains a $T_1$ value and a $T_2$ value representing the time interval $[T_1, T_2]$ during which the values of the explanatory variables remain unchanged. Each record also contains the censoring status at $T_2$.

One advantage of using the counting process formulation is that you can easily obtain various residuals and influence statistics that are not available when programming statements are used to compute the values of the time-dependent variables. On the other hand, creating multiple records for the counting process formulation requires extra effort in data manipulation.

Consider a counting process style of input data set named Tumor1. It contains multiple observations for each subject in the data set Tumor. In addition to variables ID, Time, Dead, and Dose, four new variables are generated:

- $T_1$ (left endpoint of the risk interval)
- $T_2$ (right endpoint of the risk interval)
- NPap (number of papillomas in the time interval $[T_1, T_2]$)
- Status (censoring status at $T_2$)

For example, five observations are generated for the rodent that died at week 47 and that had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. The values of $T_1$, $T_2$, NPap, and Status for these five observations are $(0,27,0,0), (27,34,5,0), (34,37,6,0), (37,41,8,0), \text{ and } (41,47,10,1)$. Note that the variables ID, Time, and Dead are not needed for the estimation of the regression parameters, but they are useful for plotting the residuals.
The following SAS statements create the data set Tumor1:

```sas
data Tumor1(keep=ID Time Dead Dose T1 T2 NPap Status);
array pp{*} P1-P14;
array qq{*} P2-P15;
array tt{1:15} _temporary_
   (27 34 37 41 43 45 46 47 49 50 51 53 65 67 71);
set Tumor;
T1 = 0;
T2 = 0;
Status = 0;
if ( Time = tt[1] ) then do;
   T2 = tt[1];
   NPap = p1;
   Status = Dead;
   output;
end;
else do _i_=1 to dim(pp);
   if ( tt[_i_] = Time ) then do;
      T2 = Time;
      NPap = pp[_i_];
      Status = Dead;
      output;
   end;
   else if (tt[_i_] < Time ) then do;
      if (pp[_i_] ^= qq[_i_] ) then do;
         if qq[_i_] = . then T2 = Time;
         else T2 = tt[_i_];
      end;
      NPap = pp[_i_];
      Status = 0;
      output;
      T1 = T2;
   end;
end;
if ( Time >= tt[15] ) then do;
   T2 = Time;
   NPap = P15;
   Status = Dead;
   output;
end;
run;
```
In the following SAS statements, the counting process MODEL specification is used. The DFBETA statistics are output to a SAS data set named Out1. Note that Out1 contains multiple observations for each subject, that is, one observation for each risk interval \((T1,T2]\).

```sas
proc phreg data=Tumor1;
   model (T1,T2)*Status(0)=Dose NPap;
   output out=Out1 resmart=mart dfbeta=db1-db2/order=data;
      id ID Time Dead;
   run;
```

The output from PROC PHREG (not shown) is identical to Output 54.5.1 except for the “Summary of the Number of Event and Censored Values” table. The number of event observations remains unchanged between the two specifications of PROC PHREG, but the number of censored observations differs due to the splitting of each subject’s data into multiple observations for the counting process style of input.

Next, the MEANS procedure sums up the component statistics for each subject and outputs the results to a SAS data set named Out2.

```sas
proc means data=Out1 noprint;
   by ID Time Dead;
   var mart db1-db2;
   output out=Out2 sum=mart db_dose db_npap;
   run;
```

Finally, DFBETA statistics are plotted against subject ID for easy identification of influential points.

```sas
symbol1 v=dot h=0.8 c=blue;
axis1 label = (angle=-90 rotate=90 'DFBETA for Dose')
   minor = none
   order = (-.04 to .04 by .01);
axis2 label = (angle=-90 rotate=90 'DFBETA for NPap')
   minor = none
   order = (-.030 to .020 by .005);
title 'Plot of DFBETA';
proc gplot data=Out2;
   plot db_dose * ID / frame hminor=0 vaxis=axis1 cframe=ligr;
   plot db_npap * ID / frame hminor=0 vaxis=axis2 cframe=ligr;
   run;
```
The plots of the DFBETA statistics are shown in Output 54.5.2 and Output 54.5.3. Subject 30 appears to have a large influence on both the Dose and NPap coefficients. Subjects 31 and 35 have considerable influences on the DOSE coefficient, while subjects 22 and 44 have rather large influences on the NPap coefficient.

**Output 54.5.2.** Plot of DFBETA Statistic for DOSE versus Subject Number

**Output 54.5.3.** Plot of DFBETA Statistic for NPAP versus Subject Number
Example 54.6. Survivor Function Estimates for Specific Covariate Values

You may want to use your regression analysis results to generate predicted survival curves for subjects not in the study. This example illustrates how to use the BASELINE statement to obtain the survivor function for a new set of explanatory variable values. The various sets of explanatory variable values must be contained in a SAS data set.

In previous examples, LogBUN and HGB were identified as the most important prognostic factors for the myeloma data. Suppose you are interested in obtaining the survivor function estimates for the following two realizations of LogBUN and HGB, which are saved in a SAS data set called Inrisks.

```
data Inrisks;
   input LogBUN HGB;
datalines;
1.00 10.0
1.80 12.0
;
```

In the BASELINE statement, you specify the name of the data set (COVARIATE=Inrisks) that contains the various sets of explanatory variable values and the name of the output SAS data set (OUT=Pred1) that contains the survivor function estimates. The option SURVIVAL=S puts the variable S containing the survivor function estimates in the output data set Pred1. Similarly, the options LOWER=S_lower and UPPER=S_upper put the variables S_lower and S_upper in Pred1; these variables contain, respectively, the lower and upper 95% confidence limits for the survival. The NOPRINT option in the PROC PHREG statement suppresses the displayed output (the analysis results are shown in Example 54.1). The PRINT procedure displays the observations in the data set Pred1.

```
proc phreg data=Myeloma noprint;
   model Time*VStatus(0)=LogBUN HGB;
   baseline covariates=Inrisks out=Pred1 survival=S
      lower=S_lower upper=S_upper;
run;
proc print data=Pred1;
run;
```
Chapter 54. The PHREG Procedure

The first 32 observations of the data set Pred1 are shown in Output 54.6.1. They represent the survivor function for the realization LogBUN=1.00 and HGB=10.0. The first observation has survival time 0 and survivor function estimate 1.0. Each of the remaining 31 observations represents each unique event time in the input data set Myeloma. These observations are presented in ascending order of the event times. Likewise, the next 32 observations of the data set Pred1 (starting from the 33rd observation) represent the survivor function for the realization LogBUN=1.80 and HGB=12.0.

Output 54.6.1. Survivor Function Estimates for LogBUN=1.0 and HGB=10.0

By default, the procedure also outputs the set of survivor function estimates for LogBUN=1.3929 and HGB=10.2015, which are the sample means of LogBUN and HGB for the input data in Myeloma. (Note that in a stratified analysis, the sample means are calculated within each stratum.) The estimated survivor function estimates for these sample means are the last 32 observations in the data set Pred1. You can suppress this set of survival estimates by using the NOMEAN option in the BASELINE statement.
Example 54.6. Survivor Function Estimates for Specific Covariate Values

```sas
proc phreg data=Myeloma noprint;
  model Time*VStatus(0)=LogBUN HGB;
  baseline covariates=Inrisks out=Pred2 survival=S lower=S_lower upper=S_upper / nomean;
run;
```

The data set Pred2 consists of the first 64 observations of Pred1. If you are interested only in the survivor function estimates for the sample means of the explanatory variables, you can omit the COVARIATES= option in the BASELINE statement.

```sas
proc phreg data=Myeloma noprint;
  model Time*VStatus(0)=LogBUN HGB;
  baseline out=Pred3 survival=S lower=S_lower upper=S_upper;
run;
```

The data set Pred3 contains the last 32 observations of Pred1.

The following SAS statements are used to plot the survival curves in Pred1. For convenience, the variable Pattern is added to the data set Pred1 to identify the various patterns of explanatory variables.

```sas
data Pred1;
  set Pred1;
  if LogBUN= 1.0 and HGB=10.0 then Pattern=1;
  else if LogBUN= 1.8 and HGB=12.0 then Pattern=2;
  else Pattern=3;
legend1 label=none shape=symbol(3, .8)
  value=(f=swiss h=.8 ‘LogBUN=1.00 HGB=10.0’
    ‘LogBUN=1.80 HGB=12.0’ ‘LogBUN=1.39 HGB=10.2’);
axis1 label=(h=1 f=swiss a=90) minor=(n=1);
axis2 label=(h=1 f=swiss ‘Survival Time in Months’) minor=(n=4);
proc gplot data=Pred1;
  plot S*Time=Pattern / legend=legend1 vaxis=axis1
    haxis=axis2 cframe=ligr;
symbol1 interpol=stepLJ h=1 v=square c=blue;
symbol2 interpol=stepLJ h=1 v=diamond c=yellow;
symbol3 interpol=stepLJ h=1 v=circle c=red;
note f=swiss h=1.5 j=c ‘Myeloma Study’;
footnote h=.8 f.duplex
  ‘LogBUN=1.39 and HGB=10.2 correspond to the sample means’;
run;
```
Chapter 54. The PHREG Procedure

The survivor function estimates for these three patterns of explanatory variables are displayed in Output 54.6.2. Note that these survivor functions are portrayed as right-continuous functions.

Output 54.6.2. Survival Curves for Specific Covariate Patterns

Example 54.7. Analysis of Residuals

Residuals are used to investigate the lack of fit of a model to a given subject. You can obtain martingale and deviance residuals for the Cox proportional hazards regression analysis by requesting that they be included in the OUTPUT data set. You can plot these statistics and look for outliers.

Consider the stepwise regression analysis performed in Example 54.1. The final model included variables LogBUN and HGB. You can generate residual statistics for this analysis by refitting the model containing those variables and including an OUTPUT statement. The keywords XBETA, RESMART, and RESDEV identify new variables that contain the linear predictor scores \( z_i' \hat{\beta} \), martingale residuals, and deviance residuals. These variables are xb, mart, and dev, respectively.
Example 54.7. Analysis of Residuals

```sas
proc phreg data=Myeloma noprint;
  model Time*Vstatus(0)=LogBUN HGB;
  output out=Outp xbeta=xb resmart=mart resdev=dev;
run;
```

The following statements plot the residuals against the linear predictor scores:

```sas
proc gplot data=Outp;
  plot (mart dev)*xb / vref=0 cframe=ligr;
  symbol1 value=circle c=blue;
run;
```

The resulting plots are shown in Output 54.7.1 and Output 54.7.2. The martingale residuals are skewed because of the single event setting of the Cox model. The martingale residual plot shows an isolation point (with linear predictor score 1.09 and martingale residual -3.37), but this observation is no longer distinguishable in the deviance residual plot. In conclusion, there is no indication of a lack of fit of the model to individual observations.

**Output 54.7.1.** Martingale Residual Plot

![Martingale Residual Plot](image)
Example 54.8. Analysis of Recurrent Events Data

Recurrent events data consists of times to a number of repeated events for each sample unit; for example, times of recurrent episodes of a disease in patients. Various ways for analyzing recurrent events data are described in the section “Analysis of Multivariate Failure Time Data” on page 3247. The bladder cancer data listed in Wei, Lin, and Weissfeld (1989) is used here to illustrate these methods.

The data consist of 86 patients with superficial bladder tumors, which were removed when the patients entered the study. Of these patients, 48 were randomized into the placebo group, and 38 were randomized into the thiotepa group. Many patients had multiple recurrences of tumors during the study, and new tumors were removed at each visit. The data set contains the first four recurrences of the tumor for each patient, and each recurrence time was measured from the patient’s entry time into the study.

The data consist of the following eight variables:

- **Trt**, treatment group (1=placebo and 2=thiotepa)
- **Time**, follow-up time
- **Number**, number of initial tumors
- **Size**, initial tumor size
- **T1, T2, T3, and T4**, times of the four potential recurrences of the bladder tumor. A patient with only two recurrences has missing values in T3 and T4.
In the data set Bladder, four observations are created for each patient, one for each of the four potential tumor recurrences. In addition to values of Trt, Number, and Size for the patient, each observation contains the following variables:

- **ID**, patient’s identification (which is the sequence number of the subject)
- **Visit**, visit number (with value \( k \) for the \( k \)th potential tumor recurrence)
- **TStart**, time of the \((k-1)\)th recurrence for \( \text{Visit}=k \), or the entry time 0 if \( \text{VISIT}=1 \), or the follow-up time if the \((k-1)\)th recurrence does not occur
- **TStop**, time of the \( k \)th recurrence if \( \text{Visit}=k \) or follow-up time if the \( k \)th recurrence does not occur
- **Status**, event status of **TStop** (1=recurrence and 0=censored)

For instance, a patient with only one recurrence time at month 6, who was followed until month 10, will have values for **Visit**, **TStart**, **TStop**, and **Status** of \((1,0,6,1),(2,6,10,0),(3,10,10,0),(4,10,10,0)\). The last two observations are redundant for the intensity model and the proportional means model, but they are important for the analysis of the marginal Cox models. If the follow-up time is beyond the time of the fourth tumor recurrence, it is tempting to create a fifth observation with the time of the fourth tumor recurrence as the **TStart** value, the follow-up time as the **TStop** value, and a **Status** value of 0. However, Therneau and Grambsch (2000, Section 8.5) have warned against incorporating such observations into the analysis.

The following SAS statements create the data set Bladder:

```
data Bladder;
    keep ID TStart TStop Status Trt Number Size Visit;
    retain ID TStart 0;
    array tt T1-T4;
    infile datalines missover;
    input Trt Time Number Size T1-T4;
    ID + 1;
    TStart=0;
    do over tt;
        Visit=_i_; 
        if tt = . then do; 
            TStop=Time;
            Status=0;
        end;
        else do;
            TStop=tt;
            Status=1;
        end;
    output;
    TStart=TStop;
end;
if (TStart < Time) then delete;
datalines;
1 0 1 1
1 1 1 3
```

First, consider fitting the intensity model (Andersen and Gill 1982) and the proportional means model (Lin et al. 2000). The counting process style of input is used in the PROC PHREG specification. For the proportional means model, inference is based on the robust sandwich covariance estimate, which is requested by the COVB(AGGREGATE) option in the PROC PHREG statement. The COVM option is specified for the analysis of the intensity model to use the model-based covariance estimate. Note that some of the observations in the data set Bladder have a degenerated interval of risk. The presence of these observations does not affect the results of the analysis since none of these observations are included in any of the risk sets. However, the procedure will run more efficiently without these observations; consequently, in the following SAS statements, the WHERE clause is used to eliminate these redundant observations.

```
title 'Intensity Model and Proportional Means Model';
proc phreg data=Bladder covm covs(aggregate);
   model (TStart, TStop) * Status(0) = Trt Number Size;
   id id;
   where TStart < TStop;
run;
```
Results of fitting the intensity model and the proportional means model are shown in Output 54.8.1 and Output 54.8.2, respectively. The robust sandwich standard error estimate for Trt is larger than its model-based counterpart, rendering the effect of thiotepa less significant in the proportional means model ($p=0.0747$) than in the intensity model ($p=0.0215$).

</tbody>
</table>

Next, consider the conditional models of PWP (Prentice, Williams, and Peterson 1981). In the PWP models, the risk set for the $(k+1)$th recurrence is restricted to those patients who have experienced the first $k$ recurrences. For example, a patient who experienced only one recurrence is an event observation for the first recurrence; this patient is a censored observation for the second recurrence and should not be included in the risk set for the third or fourth recurrence. The following DATA step eliminates those observations that should not be in the risk sets, forming a new input data set (named Bladder2) for fitting the PWP models. The variable Gaptime, represented the gap times between successive recurrences, is also created.
The following statements fit the PWP total time model. Variables Trt1, Trt2, Trt3, and Trt4 are visit-specific variables for Trt; variables Number1, Number2, Number3, and Number4 are visit-specific variables for Number; and variables Size1, Size2, Size3, and Size4 are visit-specific variables for Size.

```
title 'PWP Total Time Model with Noncommon Effects';
proc phreg data=Bladder2;
  model (TStart,Tstop) * Status(0) = Trt1-Trt4 Number1-Number4 Size1-Size4;
    Trt1= Trt * (Visit=1);
    Trt2= Trt * (Visit=2);
    Trt3= Trt * (Visit=3);
    Trt4= Trt * (Visit=4);
    Number1= Number * (Visit=1);
    Number2= Number * (Visit=2);
    Number3= Number * (Visit=3);
    Number4= Number * (Visit=4);
    Size1= Size * (Visit=1);
    Size2= Size * (Visit=2);
    Size3= Size * (Visit=3);
    Size4= Size * (Visit=4);
  strata Visit;
run;
```

Results of the analysis of the PWP total time model are shown in Output 54.8.3. Note that patients who were at risk for a second recurrence are those who had a first recurrence. There is no significant treatment effect on the total time in any of the four tumor recurrences.

The following statements fit the PWP gap-time model.

```plaintext
title 'PWP Gap Time Model with Noncommon Effects';
proc phreg data=Bladder2;
  model Gaptime * Status(0) = Trt1-Trt4 Number1-Number4 Size1-Size4;
  Trt1= Trt * (Visit=1);
  Trt2= Trt * (Visit=2);
  Trt3= Trt * (Visit=3);
  Trt4= Trt * (Visit=4);
  Number1= Number * (Visit=1);
  Number2= Number * (Visit=2);
  Number3= Number * (Visit=3);
  Number4= Number * (Visit=4);
  Size1= Size * (Visit=1);
  Size2= Size * (Visit=2);
  Size3= Size * (Visit=3);
  Size4= Size * (Visit=4);
  strata Visit;
run;
```

Results of the analysis of the PWP gap-time model are shown in Output 54.8.4. Note that the regression coefficients for the first tumor recurrence are the same as those of
the total time model, since the total time and and the gap time are the same for the first recurrence. There is no significant treatment effect on the gap times for any of the four tumor recurrences.

You can fit the PWP total time model with common effects with the following SAS statements. However, the analysis is not shown here.

```sas
title2 'PWP Total Time Model with Common Effects';
proc phreg data=Bladder2;
    model (tstart,tstop) * status(0) = Trt Number Size;
    strata Visit;
run;
```

You can fit the PWP gap time model with common effects with the following statements. Again, the analysis is not shown here.

```sas
title2 'PWP Gap Time Model with Common Effects';
proc phreg data=Bladder2;
    model Gaptime * Status(0) = Trt Number Vize;
    strata Visit;
run;
```

Recurrent events data are a special case of multiple events data in which the recurrence times are regarded as multivariate failure times and the marginal approach of WLW (Wei, Lin, and Weissfeld 1989) can be used. WLW fits a Cox model to each of the component times and makes statistical inference of the regression parameters based on a robust sandwich covariance matrix estimate. No specific correlation structure is imposed on the multivariate failure times. For the $k$th marginal model, let $\beta_k$ denote the row vector of regression parameters, let $\hat{\beta}_k$ denote the maximum likelihood estimate of $\beta_k$, let $\hat{A}_k$ denote the covariance matrix obtained by inverting the
observed information matrix, and let \( \mathbf{R}_k \) denote the matrix of score residuals. WLW showed that the joint distribution of \((\hat{\beta}_1, \ldots, \hat{\beta}_4)\)' can be approximated by a multivariate normal distribution with mean vector \((\beta_1, \ldots, \beta_4)\)' and robust covariance matrix

\[
\begin{pmatrix}
V_{11} & V_{12} & V_{13} & V_{14} \\
V_{21} & V_{22} & V_{23} & V_{24} \\
V_{31} & V_{32} & V_{33} & V_{34} \\
V_{41} & V_{42} & V_{43} & V_{44}
\end{pmatrix}
\]

with the submatrix \( V_{ij} \) given by

\[ V_{ij} = \hat{A}_i (R_i' R_j) \hat{A}_j \]

In this example, there are four marginal proportional hazards models, one for each potential recurrence time. Instead of fitting one model at a time, you can fit all four marginal models in one analysis by using the STRATA statement and model-specific covariates. Using the \texttt{Visit} as the STRATA variable on the input data set \texttt{Bladder}, PROC PHREG simultaneously fits all four marginal models, one for each \texttt{Visit} value. The \texttt{COVS(AGGREGATE)} option is specified to compute the robust sandwich variance estimate by summing up the score residuals for each distinct pattern of \texttt{ID} value. The \texttt{TEST} statement \texttt{TREATMENT} is used to perform the global test of no treatment effect for each tumor recurrence, the \texttt{AVERAGE} option is specified to estimate the parameter for the common treatment effect, and the \texttt{E} option displays the optimal weights for the common treatment effect.

```plaintext
proc phreg data=Bladder covs(aggregate);
  model TStop*Status(0)=Trt1-Trt4 Number1-Number4 Size1-Size4;
  Trt1= Trt * (Visit=1);
  Trt2= Trt * (Visit=2);
  Trt3= Trt * (Visit=3);
  Trt4= Trt * (Visit=4);
  Number1= Number * (Visit=1);
  Number2= Number * (Visit=2);
  Number3= Number * (Visit=3);
  Number4= Number * (Visit=4);
  Size1= Size * (Visit=1);
  Size2= Size * (Visit=2);
  Size3= Size * (Visit=3);
  Size4= Size * (Visit=4);
  strata Visit;
  id ID;
  TREATMENT: test trt1,trt2,trt3,trt4/average e;
run;
```
Out of the 86 patients, 47 patients have only one tumor recurrence, 29 patients have two recurrences, 22 patients have three recurrences, and 14 patients have four recurrences (Output 54.8.5). Parameter estimates for the four marginal models are shown in Output 54.8.6. The 4 DF Wald test (Output 54.8.7) indicates a lack of evidence of a treatment effect in any of the four recurrences ($p=0.4105$). The optimal weights for estimating the parameter of the common treatment effect are 0.67684, 0.25723, -0.07547, and 0.14140 for $T_{rt1}$, $T_{rt2}$, $T_{rt3}$, and $T_{rt4}$, respectively, which gives a parameter estimate of -0.5489 with a standard error estimate of 0.2853. A more sensitive test for a treatment effect is the 1 DF test based on this common parameter; however, there is still insufficient evidence for such effect at the 0.05 level ($p=0.0543$).

Example 54.9. Analysis of Clustered Data

When experimental units are naturally or artificially clustered, failure times of experimental units within a cluster are correlated. Lee, Wei, and Amato (1992) estimate the regression parameters in the Cox model by the maximum partial likelihood estimates under an independent working assumption and use a robust sandwich covariance matrix estimate to account for the intracluster dependence. A subset of data from the Diabetic Retinopathy Study (DRS) is used to illustrate the methodology as in Lin (1994).

The data consist of 197 diabetic patients who have a high risk of experiencing blindness in both eyes as defined by DRS criteria. One eye of each patient is treated with laser photocoagulation. The hypothesis of interest is whether the laser treatment delays the occurrence of blindness. Since juvenile and adult diabetes have very different courses, it is also desirable to examine how the age of onset of diabetes may affect the time of blindness. Since there are no biological differences between the left eye and the right eye, it is natural to assume a common baseline hazard function for the failure times of the left and the right eyes.
Example 54.9. Analysis of Clustered Data

Each patient is a cluster that contributes two observations to the input data set, one for each eye. The following variables are in the input data set `Blind`:

- **ID**, patient’s identification
- **Time**, failure time
- **Status**, event indicator (0=censored and 1=uncensored)
- **Treatment**, treatment received (1=laser photocoagulation and 0=otherwise)
- **DiabeticType**, type of diabetes (0=juvenile onset with age of onset at 20 or under, and 1= adult onset with age of onset over 20)

;
As a preliminary analysis, PROC FREQ is used to break down the numbers of blindness in the control and treated eyes.

```latex
proc freq data=Blind;
  table Treatment*Status;
run;
```

**Output 54.9.1.** Breakdown of Blindness in the Control and Treated Groups

</tr>
</tbody>
</table>

By the end of the study, 54 treated eyes and 101 untreated eyes have developed blindness (Output 54.9.1).

The analysis of Lee, Wei, and Amato (1992) can be carried out by the following PROC PHREG specification. The explanatory variables in this Cox model are `Treatment`, `DiabeticType`, and the `Treatment` $\times$ `DiabeticType` interaction. The COVS(AGGREGATE) is specified to compute the robust sandwich covariance matrix estimate.

```latex
proc phreg data=Blind covs(aggregate);
  model Time*Status(0)=Treatment DiabeticType Interaction;
  Interaction= Treatment * DiabeticType;
  id ID;
run;
```

The robust standard error estimates are smaller than the model-based counterparts (Output 54.9.2), since the ratio of the robust standard error estimate relative to the model-based estimate is less than 1 for each variable. Laser photocoagulation appears
to be effective ($p=0.0217$) in delaying the occurrence of blindness. The effect is much more prominent for adult onset diabetes than for juvenile onset diabetes.

**Output 54.9.2. Inference Based on the Robust Sandwich Covariance**

**Example 54.10. Model Assessment Using Cumulative Sums of Martingale Residuals (Experimental)**

The Mayo liver disease example of Lin, Wei, and Ying (1993) is reproduced here to illustrate the checking of the functional form of a covariate and the assessment of the proportional hazards assumption. The data consist of 418 patients with primary biliary cirrhosis (PBC), among which 161 had died as of the date of data listing. A subset of the variables are saved in the SAS data set Liver. The data set contains the following variables:

- **Time**, follow-up time in years
- **Status**, event indicator with value 1 for death time and value 0 for censored time
- **Age**, age in years from birth to study registration
- **Albumin**, serum albumin level in gm/dl
- **Bilirubin**, serum bilirubin level in mg/dl
- **Edema**, edema presence
- **Protime**, prothrombin time in seconds

</table>
Consider fitting a Cox model for the survival time of the PCB patients with covariates \textit{Bilirubin}, \textit{log(Protime)}, \textit{log(Albumin)}, \textit{Age} and \textit{Edema}. The log transform, which is often applied to blood chemistry measurements, is deliberately not employed for \textit{Bilirubin}. It is of interest to assess the functional form of the variable \textit{Bilirubin} in the Cox model.

```plaintext
ods html;
ods graphics on;
proc phreg data=Liver;
   model Time*Status(0)=Bilirubin logProtime logAlbumin Age Edema;
   logProtime=log(Protime);
   logAlbumin=log(Albumin);
   assess var=(Bilirubin) / resample;
run;

ods graphics off;
ods html close;
```

The ASSESS statement creates a plot of the cumulative martingale residuals against the values of the covariate \textit{Bilirubin}, which is specified in the \texttt{VAR=} option. The \texttt{RESAMPLE} option computes the \(p\)-value of a Kolmogorov-type supremum test based on a sample of 1,000 simulated residual patterns.

Parameter estimates of the model fit are shown in \textbf{Output 54.10.1}. The plot in \textbf{Output 54.10.2} displays the observed cumulative martingale residual process for \textit{Bilirubin} together with 20 simulated realizations from the null distribution. This graphical
display is requested by specifying the experimental ODS GRAPHICS statement and the experimental ASSESS statement. For general information about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the PHREG procedure, see the section “ODS Graphics” on page 3271. It is obvious that the observed process is atypical compared to the simulated realizations. Also, none of the 1,000 simulated realizations has an absolute maximum exceeding that of the observed cumulative martingale residual process. Both the graphical and numerical results indicate that a transform is deemed necessary for Bilirubin in the model.

The cumulative martingale residual plots in Output 54.10.3 provide guidance in suggesting a more appropriate functional form for a covariate. The four curves were created from simple forms of misspecification using 1,000 simulated times from a exponential model with 20% censoring. The true and fitted models are shown in Table 54.3.

The curve of observed cumulative martingale residuals in Output 54.10.2 most resembles the behavior of the curve in plot (a) of Output 54.10.3, indicating that $\log(\text{Bilirubin})$ might be a more appropriate term in the model than $\text{Bilirubin}$.

Next, the analysis of the natural history of the PBC is repeated with $\log(\text{Bilirubin})$ replacing $\text{Bilirubin}$, and the functional form of $\log(\text{Bilirubin})$ is assessed. Also assessed is the proportional hazards assumption for the Cox model.

```sql
ods html;
ods graphics on;
proc phreg data=Liver;
  model Time*Status(0)=logBilirubin logProtime logAlbumin Age Edema;
```
logBilirubin=log(Bilirubin);
logProtime=log(Protime);
logAlbumin=log(Albumin);
assess var=(logBilirubin) ph / crpanel resample seed=19;
run;
ods graphics off;
ods html close;

The SEED= option specifies a integer seed for generating random numbers. The CRPANEL option in the ASSESS statement requests a panel of four plots. Each plot displays the observed cumulative martingale residual process along with two simulated realizations. The PH option checks the proportional hazards assumption of the model by plotting the observed standardized score process with 20 simulated realizations for each covariate in the model.

Output 54.10.4 displays the parameter estimates of the fitted model. The cumulative martingale residual plots in Output 54.10.5 and Output 54.10.6 show that the observed martingale residual process is more typical of the simulated realizations. The p-value for the Kolmogorov-type supremum test based on 1,000 simulations is 0.052, indicating that the log transform is a much improved functional form for Bilirubin.

Chapter 55. The PLAN Procedure
The PLAN procedure constructs designs and randomizes plans for factorial experiments, especially nested and crossed experiments and randomized block designs. PROC PLAN can also be used for generating lists of permutations and combinations of numbers. The PLAN procedure can construct the following types of experimental designs:

- full factorials, with and without randomization
- certain balanced and partially balanced incomplete block designs
- generalized cyclic incomplete block designs
- Latin square designs

For other kinds of experimental designs, especially fractional factorial, response surface, and orthogonal array designs, refer to the FACTEX and OPTEX procedures and the ADX Interface in SAS/QC software.

PROC PLAN generates designs by first generating a selection of the levels for the first factor. Then, for the second factor, PROC PLAN generates a selection of its levels for each level of the first factor. In general, for a given factor, the PLAN procedure generates a selection of its levels for all combinations of levels for the factors that precede it. The selection can be done in five different ways:

- randomized selection, for which the levels are returned in a random order
- ordered selection, for which the levels are returned in a standard order every time a selection is generated
- cyclic selection, for which the levels returned are computed by cyclically permuting the levels of the previous selection
- permuted selection, for which the levels are a permutation of the integers $1, \ldots, n$
- combination selection, for which the $m$ levels are selected as a combination of the integers $1, \ldots, n$ taken $m$ at a time

The randomized selection method can be used to generate randomized plans. Also, by appropriate use of cyclic selection, any of the designs in the very wide class of generalized cyclic block designs (Jarrett and Hall 1978) can be generated.

There is no limit to the depth to which the different factors can be nested, and any number of randomized plans can be generated.
You can also declare a list of factors to be selected simultaneously with the lowest (that is, the most nested) factor. The levels of the factors in this list can be seen as constituting the treatment to be applied to the cells of the design. For this reason, factors in this list are called treatments. With this list, you can generate and randomize plans in one run of PROC PLAN.

### Getting Started

#### Three Replications with Four Factors

Suppose you want to determine if the order in which four drugs are given affects the response of a subject. If you have only three subjects to test, you can use the following statements to design the experiment.

```plaintext
proc plan seed=27371;
   factors Replicate=3 ordered Drug=4;
run;
```

These statements produce a design with three replicates of the four levels of the factor Drug arranged in random order. The three levels of Replicate are arranged in order, as shown in Figure 55.1

![Figure 55.1. Three Replications and Four Factors](image)

You may also want to apply one of four different treatments to each cell of this plan (for example, applying different amounts of each drug). The following statements create the output shown in Figure 55.2.

```plaintext
factors Replicate=3 ordered Drug=4;
treatments Treatment=4;
run;
```
Randomly Assigning Subjects to Treatments

You can use the PLAN procedure to design a completely randomized design. Suppose you have 12 experimental units, and want to assign one of two treatments to each unit. Use a DATA step to store the unrandomized design in a SAS data set, then call PROC PLAN to randomize it by specifying one RANDOM factor of 12 levels. The following statements produce Figure 55.3 and Figure 55.4:

title 'Completely Randomized Design';
/* The unrandomized design */
data a;
   do unit=1 to 12;
      if (unit <= 6) then treat=1;
      else treat=2;
      output;
   end;
run;

/* Randomize the design */
proc plan seed=27371;
   factors unit=12;
   output data=a out=b;
run;

proc sort data=b;
   by unit;
proc print;
run;
Figure 55.3 shows that the 12 levels of the unit factor have been randomly reordered and then lists the new ordering.

Figure 55.4. A Completely Randomized Design for Two Treatments

You can also generate the plan by using a TREATMENTS statement instead of a DATA step. The following statements generate the same plan.

```plaintext
proc plan seed=27371;
  factors unit=12;
  treatments treat=12 cyclic (1 1 1 1 1 1 1 1 2 2 2 2 2 2 2);
  output out=b;
run;
```
Syntax

The following statements are available in PROC PLAN.

```
PROC PLAN < options > ;
   FACTORS factor-selections < / NOPRINT > ;
   OUTPUT OUT=SAS-data-set < factor-value-settings > ;
   TREATMENTS factor-selections ;
```

To use PROC PLAN, you need to specify the PROC PLAN statement and at least one FACTORS statement before the first RUN statement. The TREATMENTS statement, OUTPUT statement, and additional FACTORS statements can appear either before the first RUN statement or after it. The rest of this section gives detailed syntax information for each of the statements, beginning with the PROC PLAN statement. The remaining statements are described in alphabetical order.

You can use PROC PLAN interactively by specifying multiple groups of statements, separated by RUN statements. For details, see the “Using PROC PLAN Interactively” section on page 3346.

PROC PLAN Statement

```
PROC PLAN < options > ;
```

The PROC PLAN statement starts the PLAN procedure and, optionally, specifies a random number seed or a default method for selecting levels of factors. By default, the procedure uses a random number seed generated from reading the time of day from the computer’s clock and randomly selects levels of factors. These defaults can be modified with the SEED= and ORDERED options, respectively. Unlike many SAS/STAT procedures, the PLAN procedure does not have a DATA= option in the PROC statement; in this procedure, both the input and output data sets are specified in the OUTPUT statement.

You can specify the following options in the PROC PLAN statement:

**SEED=number**

specifies an integer used to start the pseudo-random number generator for selecting factor levels randomly. If you don’t specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

**ORDERED**

selects the levels of the factor as the integers 1, 2, . . ., m, in order. For more detail, see the “Selection-Types” section on page 3340 and see the “Specifying Factor Structures” section on page 3348.
FACTORS Statement

FACTORS  factor-selections < / NOPRINT > ;

The FACTORS statement specifies the factors of the plan and generates the plan. Taken together, the factor-selections specify the plan to be generated; more than one factor-selection request can be used in a FACTORS statement. The form of a factor-selection is

\[ name=m < OF n > < selection-type > \]

where

- \( name \) is a valid SAS name. This gives the name of a factor in the design.
- \( m \) is a positive integer that gives the number of values to be selected. If \( n \) is specified, the value of \( m \) must be less than or equal to \( n \).
- \( n \) is a positive integer that gives the number of values to be selected from.
- selection-type specifies one of five methods for selecting \( m \) values. Possible values are COMB, CYCLIC, ORDERED, PERM or RANDOM. The CYCLIC selection-type has additional optional specifications that enable you to specify an initial block of numbers to be cyclically permuted and an increment used to permute the numbers. By default, the selection-type is RANDOM, unless you use the ORDERED option in the PROC PLAN statement. In this case, the default selection-type is ORDERED. For details, see the following section, “Selection-Types”; for examples, see the “Syntax Examples” section.

The following option can appear in the FACTORS statement after the slash:

NOPRINT

suppresses the display of the plan. This is particularly useful when you require only an output data set. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

Selection-Types

PROC PLAN interprets selection-type as follows:

- **RANDOM** selects the \( m \) levels of the factor randomly without replacement from the integers \( 1, 2, \ldots, n \). Or, if \( n \) is not specified, RANDOM selects levels by randomly ordering the integers \( 1, 2, \ldots, m \).
- **ORDERED** selects the levels of the factor as the integers \( 1, 2, \ldots, m \), in that order.
- **PERM** selects the \( m \) levels of the factor as a permutation of the integers \( 1, \ldots, m \) according to an algorithm that cycles through all \( m! \) permutations. The permutations are produced in a sorted standard order; see Example 55.6 on page 3358.
COMB selects the \( m \) levels of the factor as a combination of the integers 1, \ldots, \( n \) taken \( m \) at a time, according to an algorithm that cycles through all \( n!/(m!(n-m)!) \) combinations. The combinations are produced in a sorted standard order; see Example 55.6 on page 3358.

CYCLIC \(<(\text{initial-block})>\,<\text{increment}>\>

selects the levels of the factor by cyclically permuting the integers 1, 2, \ldots, \( n \). Wrapping occurs at \( m \) if \( n \) is not specified, and at \( n \) if \( n \) is specified. Additional optional specifications are as follows:

With the selection-type CYCLIC, you can optionally specify an initial-block and an increment. The initial-block must be specified within parentheses, and it specifies the block of numbers to permute. The first permutation is the block you specify, the second is the block permuted by 1 (or by the increment you specify), and so on. By default, the initial-block is the integers 1, 2, \ldots, \( m \). If you specify an initial-block, it must have \( m \) values. Values specified in the initial-block do not have to be given in increasing order.

The increment specifies the increment by which to permute the block of numbers. By default, the increment is 1.

**Syntax Examples**

This section gives some simple syntax examples. For more complex examples and details on how to generate various designs, see the “Specifying Factor Structures” section on page 3348. The examples in this section assume that you use the default random selection method and do not use the ORDERED option in the PROC PLAN statement.

The following specification generates a random permutation of the numbers 1, 2, 3, 4, and 5.

\[
factors A=5;
\]

The following specification generates a random permutation of 5 of the integers from 1 to 8, selected without replacement.

\[
factors A=5\ of\ 8;
\]

Adding the ORDERED selection-type to the two previous specifications generates an ordered list of the integers 1 to 5. The following specification cyclically permutes the integers 1, 2, 3, and 4.

\[
factors A=4\ cyclic;
\]

Since this simple request generates only one permutation of the numbers, the procedure generates an ordered list of the integers 1 to 4. The following specification cyclically permutes the integers 5 to 8.
factors A=4 of 8 cyclic (5 6 7 8);

In this case, since only one permutation is performed, the procedure generates an ordered list of the integers 5 to 8. The following specification produces an ordered list for A, with values 1 and 2.

factors A=2 ordered B=4 of 8 cyclic (5 6 7 8) 2;

The associated factor levels for B are 5, 6, 7, 8 for level 1 of A; and 7, 8, 1, 2 for level 2 of A.

**Handling More than One Factor-Selection**

For cases with more than one factor-selection in the same FACTORS statement, PROC PLAN constructs the design as follows:

1. PROC PLAN first generates levels for the first factor-selection. These levels are permutations of integers (1, 2, and so on) appropriate for the selection type chosen. If you do not specify a selection type, PROC PLAN uses the default (RANDOM); if you specify the ORDERED option in the PROC PLAN statement, the procedure uses ORDERED as the default selection type.
2. For every integer generated for the first factor-selection, levels are generated for the second factor-selection. These levels are generated according to the specifications following the second equal sign.
3. This process is repeated until levels for all factor-selections have been generated.

The following statements give an example of generating a design with two random factors:

```plaintext
proc plan;
   factors One=4 Two=3;
run;
```

The procedure first generates a random permutation of the integers 1 to 4 and then, for each of these, generates a random permutation of the integers 1 to 3. You can think of factor Two as being nested within factor One, where the levels of factor One are to be randomly assigned to 4 units.

As another example, six random permutations of the numbers 1, 2, 3 can be generated by specifying

```plaintext
proc plan;
   factors a=6 ordered b=3;
run;
```
OUTPUT Statement

OUTPUT OUT=SAS-data-set < DATA=SAS-data-set >
< factor-value-settings > ;

The OUTPUT statement applies only to the last plan generated. If you use PROC PLAN interactively, the OUTPUT statement for a given plan must be immediately preceded by the FACTORS statement (and the TREATMENTS statement, if appropriate) for the plan. See the “Output Data Sets” section on page 3346 for more information on how output data sets are constructed. You can specify the following options in the OUTPUT statement:

OUT=SAS-data-set
DATA=SAS-data-set

You can use the OUTPUT statement both to output the last plan generated and to use the last plan generated to randomize another SAS data set.

When you specify only the OUT= option in the OUTPUT statement, PROC PLAN saves the last plan generated to the specified data set. The output data set contains one variable for each factor in the plan and one observation for each cell in the plan. The value of a variable in a given observation is the level of the corresponding factor for that cell. The OUT= option is required.

When you specify both the DATA= and OUT= options in the OUTPUT statement, then PROC PLAN uses the last plan generated to randomize the input data set (DATA=), saving the results to the output data set (OUT=). The output data set has the same form as the input data set but has modified values for the variables that correspond to factors (see the “Output Data Sets” section on page 3346 for details). Values for variables not corresponding to factors are transferred without change.

factor-value-settings

specify the values input or output for the factors in the design. The form for factor-value-settings is different when only an OUT= data set is specified and when both OUT= and DATA= data sets are specified. Both forms are discussed in the following section.

Factor-Value-Settings with Only an OUT= Data Set

When you specify only an OUT= data set, the form for each factor-value-setting specification is one of the following:

factor-name < NVALS=list-of-n-numbers >
< ORDERED | RANDOM >

or

factor-name < CVALS=list-of-n-strings >
< ORDERED | RANDOM >

where

factor-name is a factor in the last FACTORS statement preceding the OUTPUT statement.
Chapter 55. The PLAN Procedure

NVALS= lists \( n \) numeric values for the factor. By default, the procedure uses NVALS=(1 2 3 \cdots n).

CVALS= lists \( n \) character strings for the factor. Each string can have up to 40 characters, and each string must be enclosed in quotes. Warning: When you use the CVALS= option, the variable created in the output data set has a length equal to the length of the longest string given as a value; shorter strings are padded with trailing blanks. For example, the values output for the first level of a two-level factor with the following two different specifications are not the same.

\[
\text{CVALS}=('\text{String 1}' 'String 2')
\]

\[
\text{CVALS}=('\text{String 1}' 'A longer string')
\]

The value output with the second specification is ‘String 1’ followed by seven blanks. In order to match two such values (for example, when merging two plans), you must use the TRIM function in the DATA step (refer to SAS Language Reference: Dictionary).

ORDERED | RANDOM specifies how values (those given with the NVALS= or CVALS= option, or the default values) are associated with the levels of a factor (the integers 1, 2, \ldots, \( n \)). The default association type is ORDERED, for which the first value specified is output for a factor level setting of 1, the second value specified is output for a level of 2, and so on. You can also specify an association type of RANDOM, for which the levels are associated with the values in a random order. Specifying RANDOM is useful for randomizing crossed experiments (see the “Randomizing Designs” section on page 3351).

The following statements give an example of using the OUTPUT statement with only an OUT= data set and with both the NVALS= and CVALS= specifications.

```sas
proc plan;
  factors a=6 ordered b=3;
  output out=design a nvals=(10 to 60 by 10)
    b cvals=('HSX' 'SB2' 'DNY');
run;
```

The DESIGN data set contains two variables, a and b. The values of the variable a are 10 when factor a equals 1, 20 when factor a equals 2, and so on. Values of the variable b are ‘HSX’ when factor b equals 1, ‘SB2’ when factor b equals 2, and ‘DNY’ when factor b equals 3.

Factor-Value-Settings with OUT= and DATA= Data Sets

If you specify an input data set with DATA=, then PROC PLAN assumes that each factor in the last plan generated corresponds to a variable in the input set. If the variable name is different from the name of the factor to which it corresponds, the two can be associated in the values specification by
Then, the NVALS= or CVALS= specification can be used. The values given by NVALS= or CVALS= specify the input values as well as the output values for the corresponding variable.

Since the procedure assumes that the collection of input factor values constitutes a plan position description (see the “Output Data Sets” section on page 3346), the values must correspond to integers less than or equal to \( m \), the number of values selected for the associated factor. If any input values do not correspond, then the collection does not define a plan position, and the corresponding observation is output without changing the values of any of the factor variables.

The following statements demonstrate the use of factor-value settings. The input SAS data set `a` contains variables `Block` and `Plot`, which are renamed `Day` and `Hour`, respectively.

```
proc plan;
   factors Day=7 Hour=6;
   output data=a out=b
      Block = Day cvals=('Mon' 'Tue' 'Wed' 'Thu'
                         'Fri' 'Sat' 'Sun')
          Plot = Hour;
run;
```

For another example of using both a DATA= and OUT= data set, see the “Randomly Assigning Subjects to Treatments” section on page 3337.

**TREATMENTS Statement**

The TREATMENTS statement specifies the treatments of the plan to generate, but it does not generate a plan. If you supply several FACTORS and TREATMENTS statements before the first RUN statement, the procedure uses only the last TREATMENTS specification and applies it to the plans generated by each of the FACTORS statements. The TREATMENTS statement has the same form as the FACTORS statement. The individual factor-selections also have the same form as in the FACTORS statement:

```
nname=m < OF n > < selection-type >
```

The procedure generates each treatment simultaneously with the lowest (that is, the most nested) factor in the last FACTORS statement. The \( m \) value for each treatment must be at least as large as the \( m \) for the most-nested factor.

The following statements give an example of using both a FACTORS and a TREATMENTS statement. First the FACTORS statement sets up the rows and columns of a \( 3 \times 3 \) square (factors \( r \) and \( c \)). Then, the TREATMENTS statement augments the square with two cyclic treatments. The resulting design is a \( 3 \times 3 \) Graeco-Latin square, a type of design useful in main-effects factorial experiments.
Chapter 55. The PLAN Procedure

proc plan;
  factors r=3 ordered c=3 ordered;
  treatments a=3 cyclic
    b=3 cyclic 2;
run;

The resulting Graeco-Latin square design is reproduced below. Notice how the values of \( r \) and \( c \) are ordered \((1, 2, 3)\) as requested.

Details

Using PROC PLAN Interactively

After specifying a design with a FACTORS statement and running PROC PLAN with a RUN statement, you can generate additional plans and output data sets without reinvoking PROC PLAN.

In PROC PLAN, all statements can be used interactively. You can execute statements singly or in groups by following the single statement or group of statements with a RUN statement.

If you use PROC PLAN interactively, you can end the procedure with a DATA step, another PROC step, an ENDSAS statement, or a QUIT statement. The syntax of this statement is

```markdown
quit;
```

When you use PROC PLAN interactively, additional RUN statements do not end the procedure but tell PROC PLAN to execute additional statements.

Output Data Sets

To understand how PROC PLAN creates output data sets, you need to look at how the procedure represents a plan. A plan is a list of values for all the factors, the values being chosen according to the factor-selection requests you specify. For example, consider the plan produced by the following statements:

```markdown
proc plan seed=12345;
  factors a=3 b=2;
run;
```
The plan as displayed by PROC PLAN is shown in Figure 55.5.

The PLAN Procedure

3 2 1

Figure 55.5. A Simple Plan

The first cell of the plan has a=2 and b=2, the second a=2 and b=1, the third a=1
and b=1, and so on. If you output the plan to a data set with the OUTPUT statement,
by default the output data set contains a numeric variable with that factor’s name; the
values of this numeric variable are the numbers of the successive levels selected for
the factor in the plan. For example, the following statements produce Figure 55.6.

    proc plan seed=12345;
    factors a=3 b=2;
    output out=out;
    proc print data=out;
    run;

<table>
<thead>
<tr>

<td>1</td>
</tr>
</tbody>
</table>

Figure 55.6. Output Data Set from Simple Plan

Alternatively, you can specify the values that are output for a factor with the CVALS= or NVALS= option. Also, you can specify that the internal values be associated with
the output values in a random order with the RANDOM option. See the “OUTPUT
Statement” section on page 3343.

If you also specify an input data set (DATA=), each factor is associated with a vari-
able in the DATA= data set. This occurs either implicitly by the factor and variable
having the same name or explicitly as described in the specifications for the OUTPUT
statement. In this case, the values of the variables corresponding to the factors are
first read and then interpreted as describing the position of a cell in the plan. Then
the respective values taken by the factors at that position are assigned to the variables
in the OUT= data set. For example, consider the data set defined by the following statements.

```plaintext
data in;
  input a b;
datalines;
  1 1
  2 1
  3 1
;
```

Suppose you specify this data set as an input data set for the OUTPUT statement.

```plaintext
proc plan seed=12345;
  factors a=3 b=2;
  output out=out data=in;
proc print data=out;
run;
```

PROC PLAN interprets the first observation as referring to the cell in the first row and column of the plan, since \( a=1 \) and \( b=1 \); likewise, the second observation is interpreted as the cell in the second row and first column, and the third observation as the cell in the third row and first column. In the output data set \( a \) and \( b \) have the values they have in the plan at these positions, as shown in Figure 55.7.

<table>

<td>2</td>
</tr>
</tbody>
</table>

**Figure 55.7.** Output Form of Input Data Set from Simple Plan

When the factors are random, this has the effect of randomizing the input data set in the same manner as the plan produced (see the “Randomizing Designs” section on page 3351 and the “Randomly Assigning Subjects to Treatments” section on page 3337).

### Specifying Factor Structures

By appropriately combining features of the PLAN procedure, you can construct an extensive set of designs. The basic tools are the *factor-selections*, which are used in the FACTORS and TREATMENTS statements. Table 55.1 summarizes how the procedure interprets various *factor-selections* (assuming that the ORDERED option is not specified in the PROC PLAN statement).
### Table 55.1. Factor Selection Interpretation

<td>t=15</td>
<td>lists a random ordering of the numbers $1, 2, \ldots, 15$.</td>
</tr>
<tr>
<td>name=m</td>
<td>cyclically permute the integers $1, 2, \ldots, m$.</td>
<td>t=5 cyclic</td>
<td>selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,1; then 3,4,5,1,2; and so on.</td>
</tr>
<tr>
<td>name=m of n</td>
<td>choose a random sample of $m$ integers (without replacement) from the set of integers $1, 2, \ldots, n$.</td>
<td>t=5 of 15</td>
<td>lists a random selection of 5 numbers from 1 to 15. First, the procedure selects 5 numbers and then arranges them in random order.</td>
</tr>
<tr>
<td>name=m of n</td>
<td>has the same effect as name=m ordered.</td>
<td>t=5 of 15 ordered</td>
<td>lists the integers 1 to 5 in increasing order (same as t=5 ordered).</td>
</tr>
<tr>
<td>name=m of n</td>
<td>permute $m$ of the $n$ integers.</td>
<td>t=5 of 30 cyclic</td>
<td>selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,6; then 3,4,5,6,7; and so on. The 30th iteration 30,1,2,3,4; the 31st iteration produces 1,2,3,4,5; and so on.</td>
</tr>
<tr>
<td>name=m</td>
<td>produce a list of all permutations of $m$ integers.</td>
<td>t=5 perm</td>
<td>lists the integers 1,2,3,4,5 on the first iteration; on the second lists 1,2,3,5,4; and on the 119th iteration lists 5,4,3,1,2; and on the last (120th) lists 5,4,3,2,1.</td>
</tr>
<tr>
<td>name=m of n</td>
<td>choose combinations of $m$ integers from $n$ integers.</td>
<td>t=3 of 5 comb</td>
<td>lists all combinations of 5 choose 3 integers. The first iteration is 1,2,3; the second is 1,2,4; the third is 1,2,5; and so on until the last iteration 3,4,5.</td>
</tr>
</tbody>
</table>
Table 55.1. (continued)

<table>
<thead>
<tr>
<th>Form of Request</th>
<th>Interpretation</th>
<th>Example</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>name=m of n cyclic (initial-block)</td>
<td>permute $m$ of the $n$ integers, starting with the values specified in the initial-block.</td>
<td>( t=4 ) of 30 cyclic ((2\ 10\ 15\ 18))</td>
<td>selects the integers 2,10,15,18. On the next iteration, selects 3,11,16,19; then 4,12,17,20; and so on. The thirteenth iteration is 14,22,27,30; the fourteenth iteration is 15,23,28,1; and so on.</td>
</tr>
<tr>
<td>name=m of n cyclic (initial-block) increment</td>
<td>permute $m$ of the $n$ integers. Start with the values specified in the initial-block, then add the increment to each value.</td>
<td>( t=4 ) of 30 cyclic ((2\ 10\ 15\ 18)) increment 2</td>
<td>selects the integers 2,10,15,18. On the next iteration, selects 4,12,17,20; then 6,14,19,22; and so on. The wrap occurs at the eighth iteration. The eighth iteration is 16,24,29,2; and so on.</td>
</tr>
</tbody>
</table>

In Table 55.1, in order for more than one iteration to appear in the plan, another name=j factor selection (with $j > 1$) must precede the example factor selection. For example, the following statements produce six of the iterations described in the last entry of Table 55.1.

```
proc plan;
   factors c=6 ordered t=4 of 30 cyclic (2 10 15 18) 2;
run;
```

The following statements create a randomized complete block design and output the design to a data set.

```
proc plan ordered;
   factors blocks=3 cell=5;
   treatments t=5 random;
   output out=rcdb;
run;
```

Table 55.2 lists other kinds of experiment designs that can be constructed by PROC PLAN, along with section and page references for them in this chapter.

Randomizing Designs

In many situations, proper randomization is crucial for the validity of any conclusions to be drawn from an experiment. Randomization is used both to neutralize the effect of any unknown systematic biases that may be involved in the design as well as to provide a basis for the assumptions underlying the analysis.

You can use PROC PLAN to randomize an already-existing design: one produced by a previous call to PROC PLAN, perhaps, or a more specialized design taken from a standard reference such as Cochran and Cox (1957). The method is to specify the appropriate block structure in the FACTORS statement and then to specify the data set where the design is stored with the DATA= option in the OUTPUT statement. For an illustration of this method, see the “Randomly Assigning Subjects to Treatments” section on page 3337.

Two sorts of randomization are provided for, corresponding to the RANDOM factor selection and association types in the FACTORS and OUTPUT statements, respectively. Designs in which factors are completely nested (for example, block designs) should be randomized by specifying that the selection type of each factor is RANDOM in the FACTORS statement, which is the default (see Example 55.3 on page 3354). On the other hand, if the factors are crossed (for example, row-and-column designs), they should be randomized by one random reassignment of their values for the whole design. To do this, specify that the association type of each factor is RANDOM in the OUTPUT statement (see Example 55.4 on page 3356).

Displayed Output

The PLAN procedure displays

- the \( m \) value for each factor, which is the number of values to be selected
- the \( n \) value for each factor, which is the number of values to be selected from
- the selection type for each factor, as specified in the FACTORS statement
- the initial block and increment number for cyclic factors
- the factor value selections making up each plan

In addition, notes are written to the log giving the starting and ending values of the random number seed for each call to PROC PLAN.
ODS Table Names

PROC PLAN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Examples

Example 55.1. A Split-Plot Design

This plan is appropriate for a split-plot design with main plots forming a randomized complete block design. In this example, there are three blocks, four main plots per block, and two subplots per main plot. First, three random permutations (one for each of the blocks) of the integers 1, 2, 3, and 4 are produced. The four integers correspond to the four levels of the main plot factor a; the permutation determines how the levels of a are assigned to the main plots within a block. For each of these twelve numbers (four numbers per block for three blocks), a random permutation of the integers 1 and 2 is produced. Each two-integer permutation determines the assignment of the two levels of the subplot factor b within a main plot. The following statements produce Output 55.1.1:

```plaintext
title 'Split Plot Design';
proc plan seed=37277;
factors block=3 ordered a=4 b=2;
run;
```
Example 55.2. A Hierarchical Design

In this example, three plants are nested within four pots, which are nested within three houses. The FACTORS statement requests a random permutation of the numbers 1, 2, and 3 to choose Houses randomly. The second step requests a random permutation of the numbers 1, 2, 3, and 4 for each of those first three numbers to randomly assign Pots to Houses. Finally, the FACTORS statement requests a random permutation of 1, 2, and 3 for each of the twelve integers in the second set of permutations. This last step randomly assigns Plants to Pots. The following statements produce Output 55.2.1:

```sas
title 'Hierarchical Design';
proc plan seed=17431;
  factors Houses=3 Pots=4 Plants=3 / noprint;
  output out=nested;
run;
proc print data=nested;
run;
```

Example 55.3. An Incomplete Block Design

Jarrett and Hall (1978) give an example of a generalized cyclic design with good efficiency characteristics. The design consists of two replicates of 52 treatments in 13 blocks of size 8. The following statements use the PLAN procedure to generate this design in an appropriately randomized form and store it in a SAS data set. Then, the TABULATE procedure is used to display the randomized plan. The following statements produce Output 55.3.1 and Output 55.3.2:

```sas
   title 'Generalized Cyclic Block Design';
   proc plan seed=33373;
      treatments trtmts=8 of 52 cyclic (1 2 3 4 32 43 46 49) 4;
      factors blocks=13 plots=8;
      output out=c;
   quit;

   proc tabulate;
      class blocks plots;
      var trtmts;
```
Example 55.3. An Incomplete Block Design

table blocks, plots*(trtmts*f=8.) / rts=8;
run;

Example 55.4. A Latin Square Design

All of the preceding examples involve designs with completely nested block structures, for which PROC PLAN was especially designed. However, by appropriate coordination of its facilities, a much wider class of designs can be accommodated. A Latin square design is based on experimental units that have a row-and-column block structure. The following example uses the CYCLIC option for a treatment factor trtmts to generate a simple $4 \times 4$ Latin square. Randomizing a Latin square design involves randomly permuting the row, column, and treatment values independently. In order to do this, use the RANDOM option in the OUTPUT statement of PROC PLAN. The example also uses factor-value-settings in the OUTPUT statement. The following statements produce Output 55.4.1:
Example 55.5. A Generalized Cyclic Incomplete Block Design

The following statements depict how to create an appropriately randomized generalized cyclic incomplete block design for \( v \) treatments (given by the value of \( t \)) in \( b \) blocks (given by the value of \( b \)) of size \( k \) (with values of \( p \) indexing the cells within a block) with initial block \((e_1 e_2 \cdots e_k)\) and increment number \( i \).

```sas
factors b=b p=k;
treatments t=k of v cyclic (e_1 e_2 \cdots e_k) i;
```
For example, the specification

```sql
proc plan seed=37430;
  factors b=10 p=4;
  treatments t=4 of 30 cyclic (1 3 4 26) 2;
run;
```

generates the generalized cyclic incomplete block design given in Example 1 of Jarrett and Hall (1978), which is given by the rows and columns of the plan associated with the treatment factor \( t \) in Output 55.5.1.

### Example 55.6. Permutations and Combinations

Occasionally, you may need to generate all possible permutations of \( n \) things, or all possible combinations of \( n \) things taken \( m \) at a time.

For example, suppose you are planning an experiment in cognitive psychology where you want to present four successive stimuli to each subject. You want to observe each permutation of the four stimuli. The following statements use PROC PLAN to create a data set containing all possible permutations of 4 numbers in random order.
title 'All Permutations of 1,2,3,4';
proc plan seed=60359;
   factors Subject = 24
                  Order = 4 ordered;
   treatments Stimulus = 4 perm;
   output out=Psych;
proc sort data=Psych out=Psych;
   by Subject Order;
proc tabulate formchar=' ' noseps;
   class Subject Order;
   var Stimulus;
   table Subject, Order*(Stimulus*f=8.)*sum=' ' / rts=9;
run;

The variable Subject is set at 24 levels because there are $4! = 24$ total permutations to be listed. If Subject > 24, the list repeats. Output 55.6.1 and Output 55.6.2 display the PROC PLAN output. Note that the variable Subject is listed in random order.

Output 55.6.1. List of Permutations

</table>

As another example, suppose you have six alternative treatments, any four of which can occur together in a block (in no particular order). The following statements use PROC PLAN to create a data set containing all possible combinations of six numbers taken four at a time. In this case, you use ODS to create the data set.

```
title 'All Combinations of (6 Choose 4) Integers';
ods output Plan=Combinations;
proc plan;
   factors Block=15 ordered
      Treat= 4 of 6 comb;
run;
proc print data=Combinations noobs;
run;
```

The variable `Block` has 15 levels since there are a total of \(6!/(4!2!) = 15\) combinations of four integers chosen from six integers. The data set formed by ODS from the displayed plan has one row for each block, with the four values of `Treat` corresponding to four different variables, as shown in Output 55.6.4.

The PLS procedure fits models using any one of a number of linear predictive methods, including *partial least squares* (PLS). Ordinary least squares regression, as implemented in SAS/STAT procedures such as PROC GLM and PROC REG, has the single goal of minimizing sample response prediction error, seeking linear functions of the predictors that explain as much variation in each response as possible. The techniques implemented in the PLS procedure have the additional goal of accounting for variation in the predictors, under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All of the techniques implemented in the PLS procedure work by extracting successive linear combinations of the predictors, called *factors* (also called *components, latent vectors, or latent variables*), which optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives, seeking for factors that explain both response and predictor variation.

Note that the name “partial least squares” also applies to a more general statistical method that is *not* implemented in this procedure. The partial least squares method was originally developed in the 1960s by the econometrician Herman Wold (1966) for modeling “paths” of causal relation between any number of “blocks” of variables. However, the PLS procedure fits only *predictive* partial least squares models, with one “block” of predictors and one “block” of responses. If you are interested in fitting more general path models, you should consider using the CALIS procedure.

### Basic Features

The techniques implemented by the PLS procedure are

- principal components regression, which extracts factors to explain as much predictor sample variation as possible.
- reduced rank regression, which extracts factors to explain as much response variation as possible. This technique, also known as (maximum) redundancy analysis, differs from multivariate linear regression only when there are multiple responses.
- partial least squares regression, which balances the two objectives of explaining response variation and explaining predictor variation. Two different formulations for partial least squares are available: the original predictive method of Wold (1966) and the SIMPLS method of de Jong (1993).
The number of factors to extract depends on the data. Basing the model on more extracted factors improves the model fit to the observed data, but extracting too many factors can cause over-fitting, that is, tailoring the model too much to the current data, to the detriment of future predictions. The PLS procedure enables you to choose the number of extracted factors by cross validation, that is, fitting the model to part of the data, minimizing the prediction error for the unfitted part, and iterating with different portions of the data in the roles of fitted and unfitted. Various methods of cross validation are available, including one-at-a-time validation, and splitting the data into blocks. The PLS procedure also offers test set validation, where the model is fit to the entire primary input data set and the fit is evaluated over a distinct test data set.

You can use the general linear modeling approach of the GLM procedure to specify a model for your design, allowing for general polynomial effects as well as classification or ANOVA effects. You can save the model fit by the PLS procedure in a data set and apply it to new data by using the SCORE procedure.

## Getting Started

### Spectrometric Calibration

The example in this section illustrates basic features of the PLS procedure. The data are reported in Umetrics (1995); the original source is Lindberg, Persson, and Wold (1983). Suppose that you are researching pollution in the Baltic Sea, and you would like to use the spectra of samples of sea water to determine the amounts of three compounds present in samples from the Baltic Sea: lignin sulfonate (ls: pulp industry pollution), humic acids (ha: natural forest products), and optical whitener from detergent (dt). Spectrometric calibration is a type of problem in which partial least squares can be very effective. The predictors are the spectra emission intensities at different frequencies in sample spectrum, and the responses are the amounts of various chemicals in the sample.

For the purposes of calibrating the model, samples with known compositions are used. The calibration data consist of 16 samples of known concentrations of ls, ha, and dt, with spectra based on 27 frequencies (or, equivalently, wavelengths). The following statements create a SAS data set named Sample for these data.

```sas
data Sample;
  input obsnam $ v1-v27 ls ha dt @@;
  datalines;
  EM1 2766 2610 3306 3600 3438 3213 3051 2907 2844 2796
       2787 2760 2754 2670 2520 2310 2100 1917 1755 1602 1467
       1353 1260 1167 1101 1017 3.0110 0.0000 0.00
       EM2 1492 1419 1369 1158 958 887 905 929 920 887 800
       710 617 535 451 368 296 241 190 157 128 106
       89 70 65 56 50 0.0000 0.4005 0.00
       EM3 2450 2379 2400 2055 1689 1355 1109 908 750 673 644
       640 630 618 571 512 440 368 305 247 196 156
       120 98 80 61 50 0.0000 0.0000 90.63
       EM4 2751 2883 3492 3570 3282 2937 2634 2370 2187 2070 2007
```
Fitting a PLS Model

To isolate a few underlying spectral factors that provide a good predictive model, you can fit a PLS model to the 16 samples using the following SAS statements:

```sas
proc pls data=sample;
    model ls ha dt = v1-v27;
run;
```

By default, the PLS procedure extracts at most 15 factors. The procedure lists the amount of variation accounted for by each of these factors, both individual and cumulative; this listing is shown in Figure 56.1.

</tbody>
</table>

**Figure 56.1.** PLS Variation Summary

Note that all of the variation in both the predictors and the responses is accounted for by only 15 factors; this is because there are only 16 sample observations. More importantly, almost all of the variation is accounted for with even fewer factors—one or two for the predictors and three to eight for the responses.

### Selecting the Number of Factors by Cross Validation

A PLS model is not complete until you choose the number of factors. You can choose the number of factors by using cross validation, in which the data set is divided into two or more groups. You fit the model to all groups except one, then you check the capability of the model to predict responses for the group omitted. Repeating this for each group, you then can measure the overall capability of a given form of the model. The Predicted RESidual Sum of Squares (PRESS) statistic is based on the residuals generated by this process.

To select the number of extracted factors by cross validation, you specify the `CV=` option with an argument that says which cross validation method to use. For example, a common method is split-sample validation, in which the different groups are comprised of every \( n \)th observation beginning with the first, every \( n \)th observation beginning with the second, and so on. You can use the `CV=SPLIT` option to specify split-sample validation with \( n = 7 \) by default, as in the following SAS statements:

```sas
proc pls data=sample cv=split;
    model ls ha dt = v1-v27;
run;
```

The resulting output is shown in **Figure 56.2** and **Figure 56.3**.

Figure 56.3. PLS Variation Summary for Split-Sample Validated Model

The absolute minimum PRESS is achieved with six extracted factors. Notice, however, that this is not much smaller than the PRESS for three factors. By using the CVTEST option, you can perform a statistical model comparison suggested by van der Voet (1994) to test whether this difference is significant, as shown in the following SAS statements:
Chapter 56. The PLS Procedure

```plaintext
proc pls data=sample cv=split cvtest(seed=12345);
  model ls ha dt = v1-v27;
run;
```

The model comparison test is based on a rerandomization of the data. By default, the seed for this randomization is based on the system clock, but it is specified here. The resulting output is shown in Figure 56.4 and Figure 56.5.

The p-value of 0.1430 in comparing the cross-validated residuals from models with 6 and 3 factors indicates that the difference between the two models is insignificant.
therefore, the model with fewer factors is preferred. The variation summary shows that over 99% of the predictor variation and over 90% of the response variation are accounted for by the three factors.

**Predicting New Observations**

Now that you have chosen a three-factor PLS model for predicting pollutant concentrations based on sample spectra, suppose that you have two new samples. The following SAS statements create a data set containing the spectra for the new samples:

```sas
data newobs;
  input obsnam $ v1-v27 @@;
  datalines;
  EM17   3933 4518 5637 6006 5721 5187 4641 4149 3789 3579 3447 3381 3327 3234 3078 2832 2571 2274 2040 1818 1629 1470 1350 1245 1134 1050 987
         3933 4518 5637 6006 5721 5187 4641 4149 3789 3579 3447 3381 3327 3234 3078 2832 2571 2274 2040 1818 1629 1470 1350 1245 1134 1050 987
  EM25   2904 2997 3255 3150 2922 2778 2700 2646 2571 2487 2370 2250 2127 2052 1713 1419 1200 984 795 648 525 426 351 291 240 204 162
         2904 2997 3255 3150 2922 2778 2700 2646 2571 2487 2370 2250 2127 2052 1713 1419 1200 984 795 648 525 426 351 291 240 204 162
;```

You can apply the PLS model to these samples to estimate pollutant concentration. To do so, append the new samples to the original 16, and specify that the predicted values for all 18 be output to a data set, as shown in the following statements:

```sas
data all; set sample newobs;
proc pls data=all nfac=3;
  model ls ha dt = v1-v27;
  output out=pred p=p_ls p_ha p_dt;
proc print data=pred;
  where (obsnam in ('EM17','EM25'));
  var obsnam p_ls p_ha p_dt;
run;
```

The new observations are not used in calculating the PLS model, since they have no response values. Their predicted concentrations are shown in Figure 56.6.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Figure 56.6.** Predicted Concentrations for New Observations
Chapter 56. The PLS Procedure

Syntax

The following statements are available in PROC PLS. Items within the brackets < > are optional.

PROC PLS < options > ;
  BY variables ;
  CLASS variables < / option > ;
  MODEL dependent-variables = effects < / options > ;
  OUTPUT OUT= SAS-data-set < options > ;

To analyze a data set, you must use the PROC PLS and MODEL statements. You can use the other statements as needed.

PROC PLS Statement

PROC PLS < options > ;

You use the PROC PLS statement to invoke the PLS procedure and, optionally, to indicate the analysis data and method. The following options are available.

CENSCALE

lists the centering and scaling information for each response and predictor.

CV=ONE
CV=SPLIT < (n) >
CV=BLOCK < (n) >
CV=RANDOM < (cv-random-opts) >
CV=TESTSET(SAS-data-set)

specifies the cross validation method to be used. By default, no cross validation is performed. The method CV=ONE requests one-at-a-time cross validation, CV=SPLIT requests that every nth observation be excluded, CV=BLOCK requests that n blocks of consecutive observations be excluded, CV=RANDOM requests that observations be excluded at random, and CV=TESTSET(SAS-data-set) specifies a test set of observations to be used for validation (formally, this is called “test set validation” rather than “cross validation”). You can, optionally, specify n for CV=SPLIT and CV=BLOCK; the default is n = 7. You can also specify the following optional cv-random-options in parentheses after the CV=RANDOM option:

NITER=n

specifies the number of random subsets to exclude. The default value is 10.

NTEST=n

specifies the number of observations in each random subset chosen for exclusion. The default value is one-tenth of the total number of observations.

SEED=n

specifies an integer used to start the pseudo-random number generator for selecting the random test set. If you don’t specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.
The `PROC PLS Statement` is used to specify various options for a partial least squares (PLS) analysis. Here is a breakdown of the options and their meanings:

- **CVTEST < (cvtest-options) >**
  - Specifies that van der Voet’s (1994) randomization-based model comparison test be performed to test models with different numbers of extracted factors against the model that minimizes the predicted residual sum of squares; see the “Cross Validation” section on page 3384 for more information. You can also specify the following `cv-test-options` in parentheses after the `CVTEST` option:
    - **PVAL=n** specifies the cut-off probability for declaring an insignificant difference. The default value is 0.10.
    - **STAT=test-statistic** specifies the test statistic for the model comparison. You can specify either T2, for Hotelling’s $T^2$ statistic, or PRESS, for the predicted residual sum of squares. The default value is T2.
    - **NSAMP=n** specifies the number of randomizations to perform. The default value is 1000.
    - **SEED=n** specifies the seed value for randomization generation (the clock time is used by default).

- **DATA=SAS-data-set**
  - Names the SAS data set to be used by PROC PLS. The default is the most recently created data set.

- **DETAILS**
  - Lists the details of the fitted model for each successive factor. The details listed are different for different extraction methods: see the “Displayed Output” section on page 3387 for more information.

- **METHOD=PLS < (PLS-options) >**
  - **METHOD=SIMPLS**
  - **METHOD=PCR**
  - **METHOD=RRR**
    - Specifies the general factor extraction method to be used. The value PLS requests partial least squares, SIMPLS requests the SIMPLS method of de Jong (1993), PCR requests principal components regression, and RRR requests reduced rank regression. The default is METHOD=PLS. You can also specify the following optional `PLS-options` in parentheses after METHOD=PLS:
      - **ALGORITHM=NIPALS | SVD | EIG | RLGW** names the specific algorithm used to compute extracted PLS factors. NIPALS requests the usual iterative NIPALS algorithm, SVD bases the extraction on the singular value decomposition of $X'Y$, EIG bases the extraction on the eigenvalue decomposition of $Y'XX'Y$, and RLGW is an iterative approach that is efficient when there are many predictors (Ränner et al. 1994). ALGORITHM=SVD is the most accurate but least efficient approach; the default is ALGORITHM=NIPALS.
      - **MAXITER=n** specifies the maximum number of iterations for the NIPALS and RLGW algorithms. The default value is 200.
**EPSILON** = \( n \) specifies the convergence criterion for the NIPALS and RLGW algorithms. The default value is \( 10^{-12} \).

[Experimental]

MISSING=NONE
MISSING=AVG
MISSING=EM < ( EM-options ) >
specifies how observations with missing values are to be handled in computing the fit. The default is MISSING=NONE, for which observations with any missing variables (dependent or independent) are excluded from the analysis. MISSING=AVG specifies that the fit be computed by filling in missing values with the average of the nonmissing values for the corresponding variable. If you specify MISSING=EM then the procedure first computes the model with MISSING=AVG, then fills in missing values by their predicted values based on that model and computes the model again. You can also specify the following optional EM-options in parentheses after MISSING=EM:

- **MAXITER** = \( n \) specifies the maximum number of iterations for the imputation/fit loop. The default value is 1. If you specify a large value of MAXITER= then the loop will iterate until it converges (as controlled by the EPSILON= option).

- **EPSILON** = \( n \) specifies the convergence criterion for the imputation/fit loop. The default value for is \( 10^{-8} \). This option is only effective if you specify a large value for the MAXITER= option.

**NFAC** = \( n \)
specifies the number of factors to extract. The default is \( \min\{15, p, N\} \), where \( p \) is the number of predictors (the number of dependent variables for METHOD=RRR) and \( N \) is the number of runs (observations). This is probably more than you need for most applications. Extracting too many factors can lead to an over-fit model, one that matches the training data too well, sacrificing predictive ability. Thus, if you use the default NFAC= specification, you should also either use the CV= option to select the appropriate number of factors for the final model or consider the analysis to be preliminary and examine the results to determine the appropriate number of factors for a subsequent analysis.

**NOCENTER**
suppresses centering of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the “Centering and Scaling” section on page 3386 for more information.

**NOCVSTDIZE**
suppresses re-centering and re-scaling of the responses and predictors before each model is fit in the cross validation. See the “Centering and Scaling” section on page 3386 for more information.
NOPRINT suppresses the normal display of results. This is useful when you want only the output statistics saved in a data set. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

NOSCALE suppresses scaling of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the “Centering and Scaling” section on page 3386 for more information.

VARSCALE specifies that continuous model variables should be centered and scaled prior to centering and scaling the model effects in which they are involved. The rescaling specified by the VARSCALE option may be more appropriate if the model involves cross products between model variables; however, the VARSCALE option still may not produce the model you expect. See the “Centering and Scaling” section on page 3386 for more information.

VARSS lists, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

---

**BY Statement**

**BY** variables ;

You can specify a BY statement with PROC PLS to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

If you specify more than one BY statement, the procedure uses only the latest BY statement and ignores any previous ones.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PLS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).
For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the discussion in the *SAS Procedures Guide*.

**CLASS Statement**

```
CLASS variables < / option > ;
```

The CLASS statement names the classification variables to be used in the analysis. If the CLASS statement is used, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. In releases prior to Version 9, class levels were determined using no more than the first 16 characters of the formatted values. If you wish to revert to this previous behavior you can use the TRUNCATE option on the CLASS statement. In any case, you can use formats to group values into levels. Refer to the discussion of the FORMAT procedure in the *SAS Procedures Guide* and to the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

Any variable in the model that is not listed in the CLASS statement is assumed to be continuous. Continuous variables must be numeric.

You can specify the following option in the CLASS statement after a slash (/):

**TRUNCATE**

specifies that class levels should be determined using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option in order to revert to the levels as determined in releases previous to Version 9.

**MODEL Statement**

```
MODEL response-variables = predictor-effects < / options > ;
```

The MODEL statement names the responses and the predictors, which determine the \( Y \) and \( X \) matrices of the model, respectively. Usually you simply list the names of the predictor variables as the model effects, but you can also use the effects notation of PROC GLM to specify polynomial effects and interactions; see the “Specification of Effects” section on page 1784 in Chapter 32, “The GLM Procedure,” for further details. The MODEL statement is required. You can specify only one MODEL statement (in contrast to the REG procedure, for example, which allows several MODEL statements in the same PROC REG run).

You can specify the following options in the MODEL statement after a slash (/):

**INTERCEPT**

By default, the responses and predictors are centered; thus, no intercept is required in the model. You can specify the INTERCEPT option to override the default.
SOLUTION

lists the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

OUTPUT Statement

OUTPUT OUT= SAS-data-set keyword=names < ... keyword=names >;

You use the OUTPUT statement to specify a data set to receive quantities that can be computed for every input observation, such as extracted factors and predicted values. The following keywords are available:

- PREDICTED: predicted values for responses
- YRESIDUAL: residuals for responses
- XRESIDUAL: residuals for predictors
- XSCORE: extracted factors (X-scores, latent vectors, latent variables, T)
- YSCORE: extracted responses (Y-scores, U)
- STDY: standardized (centered and scaled) responses
- STDX: standardized (centered and scaled) predictors
- H: approximate leverage
- PRESS: approximate predicted residuals
- TSQUARE: scaled sum of squares of score values
- STDXSSE: sum of squares of residuals for standardized predictors
- STDYSSE: sum of squares of residuals for standardized responses

Suppose that there are \( N_x \) predictors and \( N_y \) responses and that the model has \( N_f \) selected factors.

- The keywords XRESIDUAL and STDX define an output variable for each predictor, so \( N_x \) names are required after each one.
- The keywords PREDICTED, YRESIDUAL, STDY, and PRESS define an output variable for each response, so \( N_y \) names are required after each of these keywords.
- The keywords XSCORE and YSCORE specify an output variable for each selected model factor. For these keywords, you provide only one base name, and the variables corresponding to each successive factor are named by appending the factor number to the base name. For example, if \( N_f = 3 \) then a specification of XSCORE=T would produce the variables T1, T2, and T3.
- Finally, the keywords H, TSQUARE, STDXSSE, and STDYSSE each specify a single output variable, so only one name is required after each of these keywords.
Regression Methods

All of the predictive methods implemented in PROC PLS work essentially by finding linear combinations of the predictors (factors) to use to predict the responses linearly. The methods differ only in how the factors are derived, as explained in the following sections.

Partial Least Squares

Partial least squares (PLS) works by extracting one factor at a time. Let \( X = X_0 \) be the centered and scaled matrix of predictors and \( Y = Y_0 \) the centered and scaled matrix of response values. The PLS method starts with a linear combination \( t = X_0w \) of the predictors, where \( t \) is called a score vector and \( w \) is its associated weight vector. The PLS method predicts both \( X_0 \) and \( Y_0 \) by regression on \( t \):

\[
\hat{X}_0 = tp', \quad \text{where} \quad p' = (t't)^{-1}t'X_0 \\
\hat{Y}_0 = tc', \quad \text{where} \quad c' = (t't)^{-1}t'Y_0
\]

The vectors \( p \) and \( c \) are called the X- and Y-loadings, respectively.

The specific linear combination \( t = X_0w \) is the one that has maximum covariance \( t'u \) with some response linear combination \( u = Y_0q \). Another characterization is that the X- and Y-weights \( w \) and \( q \) are proportional to the first left and right singular vectors of the covariance matrix \( X_0'Y_0 \) or, equivalently, the first eigenvectors of \( X_0'Y_0Y_0'X_0 \) and \( Y_0'X_0X_0'Y_0 \), respectively.

This accounts for how the first PLS factor is extracted. The second factor is extracted in the same way by replacing \( X_0 \) and \( Y_0 \) with the X- and Y-residuals from the first factor

\[
X_1 = X_0 - \hat{X}_0 \\
Y_1 = Y_0 - \hat{Y}_0
\]

These residuals are also called the deflated X and Y blocks. The process of extracting a score vector and deflating the data matrices is repeated for as many extracted factors as are desired.

SIMPLS

Note that each extracted PLS factor is defined in terms of different X-variables \( X_i \). This leads to difficulties in comparing different scores, weights, and so forth. The SIMPLS method of de Jong (1993) overcomes these difficulties by computing each score \( t_i = Xr_i \) in terms of the original (centered and scaled) predictors \( X \). The SIMPLS X-weight vectors \( r_i \) are similar to the eigenvectors of \( SS' = X'YY'X \),
but they satisfy a different orthogonality condition. The $r_1$ vector is just the first eigenvector $e_1$ (so that the first SIMPLS score is the same as the first PLS score), but whereas the second eigenvector maximizes

$$e'_1 S S' e_2 \text{ subject to } e'_1 e_2 = 0$$

the second SIMPLS weight $r_2$ maximizes

$$r'_1 S S' r_2 \text{ subject to } r'_1 X' X r_2 = t'_1 t_2 = 0$$

The SIMPLS scores are identical to the PLS scores for one response but slightly different for more than one response; refer to de Jong (1993) for details. The X- and Y-loadings are defined as in PLS, but since the scores are all defined in terms of $X$, it is easy to compute the overall model coefficients $B$:

$$\hat{Y} = \sum_i t_i c_i'$$

$$= \sum_i X r_i c_i'$$

$$= X B, \text{ where } B = RC'$$

**Principal Components Regression**

Like the SIMPLS method, principal components regression (PCR) defines all the scores in terms of the original (centered and scaled) predictors $X$. However, unlike both the PLS and SIMPLS methods, the PCR method chooses the X-weights/X-scores without regard to the response data. The X-scores are chosen to explain as much variation in $X$ as possible; equivalently, the X-weights for the PCR method are the eigenvectors of the predictor covariance matrix $X'X$. Again, the X- and Y-loadings are defined as in PLS; but, as in SIMPLS, it is easy to compute overall model coefficients for the original (centered and scaled) responses $Y$ in terms of the original predictors $X$.

**Reduced Rank Regression**

As discussed in the preceding sections, partial least squares depends on selecting factors $t = X w$ of the predictors and $u = Y q$ of the responses that have maximum covariance, whereas principal components regression effectively ignores $u$ and selects $t$ to have maximum variance, subject to orthogonality constraints. In contrast, reduced rank regression selects $u$ to account for as much variation in the predicted responses as possible, effectively ignoring the predictors for the purposes of factor extraction. In reduced rank regression, the Y-weights $q_i$ are the eigenvectors of the covariance matrix $\hat{Y}'_LS \hat{Y}_LS$ of the responses predicted by ordinary least squares regression; the X-scores are the projections of the Y-scores $Y q_i$ onto the X space.
Relationships Between Methods

When you develop a predictive model, it is important to consider not only the explanatory power of the model for current responses, but also how well sampled the predictive functions are, since this impacts how well the model can extrapolate to future observations. All of the techniques implemented in the PLS procedure work by extracting successive factors, or linear combinations of the predictors, that optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, principal components regression selects factors that explain as much predictor variation as possible, reduced rank regression selects factors that explain as much response variation as possible, and partial least squares balances the two objectives, seeking for factors that explain both response and predictor variation.

To see the relationships between these methods, consider how each one extracts a single factor from the following artificial data set consisting of two predictors and one response:

```plaintext
data data;
  input x1 x2 y;
datalines;
  3.37651 2.30716 0.75615

Figure 56.9. Variation Explained by First Partial Least Squares Regression Factor

Notice that, while the first reduced rank regression factor explains all of the response variation, it accounts for only about 15% of the predictor variation. In contrast, the first principal components regression factor accounts for most of the predictor variation (93%) but only 9% of the response variation. The first partial least squares factor accounts for only slightly less predictor variation than principal components but about three times as much response variation.

Figure 56.10 illustrates how partial least squares balances the goals of explaining response and predictor variation in this case.
Chapter 56. The PLS Procedure

Figure 56.10. Depiction of First Factors for Three Different Regression Methods

The ellipse shows the general shape of the 11 observations in the predictor space, with the contours of increasing $y$ overlaid. Also shown are the directions of the first factor for each of the three methods. Notice that, while the predictors vary most in the $x_1 = x_2$ direction, the response changes most in the orthogonal $x_1 = -x_2$ direction. This explains why the first principal component accounts for little variation in the response and why the first reduced rank regression factor accounts for little variation in the predictors. The direction of the first partial least squares factor represents a compromise between the other two directions.

Cross Validation

None of the regression methods implemented in the PLS procedure fit the observed data any better than ordinary least squares (OLS) regression; in fact, all of the methods approach OLS as more factors are extracted. The crucial point is that, when there are many predictors, OLS can over-fit the observed data; biased regression methods with fewer extracted factors can provide better predictability of future observations. However, as the preceding observations imply, the quality of the observed data fit cannot be used to choose the number of factors to extract; the number of extracted factors must be chosen on the basis of how well the model fits observations not involved in the modeling procedure itself.

One method of choosing the number of extracted factors is to fit the model to only part of the available data (the training set) and to measure how well models with different numbers of extracted factors fit the other part of the data (the test set). This is called test set validation. However, it is rare that you have enough data to make both parts large enough for pure test set validation to be useful. Alternatively, you can make several different divisions of the observed data into training set and test set. This is called cross validation, and there are several different types. In one-at-a-time cross validation, the first observation is held out as a single-element test set, with all
other observations as the training set; next, the second observation is held out, then
the third, and so on. Another method is to hold out successive blocks of observations
as test sets, for example, observations 1 through 7, then observations 8 through 14,
and so on; this is known as \textit{blocked} validation. A similar method is \textit{split-sample}
cross validation, in which successive groups of widely separated observations are held out
as the test set, for example, observations \{1, 11, 21, \ldots\}, then observations \{2, 12, 22,
\ldots\}, and so on. Finally, test sets can be selected from the observed data randomly;
this is known as \textit{random sample} cross validation.

Which validation you should use depends on your data. Test set validation is preferred
when you have enough data to make a division into a sizable training set and test set
that represent the predictive population well. You can specify that the number of
extracted factors be selected by test set validation by using the CV=TESTSET(\textit{data
set}) option, where \textit{data set} is the name of the data set containing the test set. If you do
not have enough data for test set validation, you can use one of the cross validation
techniques. The most common technique is one-at-a-time validation (which you can
specify with the CV=ONE option or just the CV option), unless the observed data
is serially correlated, in which case either blocked or split-sample validation may
be more appropriate (CV=BLOCK or CV=SPLIT); you can specify the number of
test sets in blocked or split-sample validation with a number in parentheses after the
CV= option. Note that CV=ONE is the most computationally intensive of the cross
validation methods, since it requires a recomputation of the PLS model for every
input observation. Also, note that using random subset selection with CV=RANDOM
may lead two different researchers to produce different PLS models on the same data
(unless the same seed is used).

Whichever validation method you use, the number of factors chosen is usually the
one that minimizes the predicted residual sum of squares (PRESS); this is the default
choice if you specify any of the CV methods with PROC PLS. However, often models
with fewer factors have PRESS statistics that are only marginally larger than the
absolute minimum. To address this, van der Voet (1994) has proposed a statistical
test for comparing the predicted residuals from different models; when you apply
van der Voet’s test, the number of factors chosen is the fewest with residuals that are
insignificantly larger than the residuals of the model with minimum PRESS.

To see how van der Voet’s test works, let $R_{i,j,k}$ be the $j$th predicted residual for
response $k$ for the model with $i$ extracted factors; the PRESS statistic is $\sum_{jk} R_{i,j,k}^2$.
Also, let $i_{\text{min}}$ be the number of factors for which PRESS is minimized. The critical
value for van der Voet’s test is based on the differences between squared predicted
residuals

$$D_{i,j,k} = R_{i,j,k}^2 - R_{i_{\text{min}},j,k}^2$$

One alternative for the critical value is $C_i = \sum_{jk} D_{i,j,k}$, which is just the difference
between the PRESS statistics for $i$ and $i_{\text{min}}$ factors; alternatively, van der Voet suggests
Hotelling’s $T^2$ statistic $C_i = d_i' S_i^{-1} d_i$, where $d_i$ is the sum of the vectors
$d_{i,j} = \{D_{i,j,1}, \ldots, D_{i,j,N_y}\}'$ and $S_i$ is the sum of squares and crossproducts matrix

$$S_i = \sum_j d_{i,j} d_{i,j}'$$
Virtually, the significance level for van der Voet’s test is obtained by comparing $C_i$ with the distribution of values that result from randomly exchanging $R^2_{i,j,k}$ and $R^2_{i\text{min},j,k}$. In practice, a Monte Carlo sample of such values is simulated and the significance level is approximated as the proportion of simulated critical values that are greater than $C_i$. If you apply van der Voet’s test by specifying the CVTEST option, then, by default, the number of extracted factors chosen is the least number with an approximate significance level that is greater than 0.10.

**Centering and Scaling**

By default, the predictors and the responses are centered and scaled to have mean 0 and standard deviation 1. Centering the predictors and the responses ensures that the criterion for choosing successive factors is based on how much variation they explain, in either the predictors or the responses or both. (See the “Regression Methods” section on page 3380 for more details on how different methods explain variation.) Without centering, both the mean variable value and the variation around that mean are involved in selecting factors. Scaling serves to place all predictors and responses on an equal footing relative to their variation in the data. For example, if $Time$ and $Temp$ are two of the predictors, then scaling says that a change of $\text{std}(Time)$ in $Time$ is roughly equivalent to a change of $\text{std}(Temp)$ in $Temp$.

Usually, both the predictors and responses should be centered and scaled. However, if their values already represent variation around a nominal or target value, then you can use the NOCENTER option in the PROC PLS statement to suppress centering. Likewise, if the predictors or responses are already all on comparable scales, then you can use the NOSCALE option to suppress scaling.

Note that, if the predictors involve crossproduct terms, then, by default, the variables are not standardized before standardizing the cross product. That is, if the $i$th values of two predictors are denoted $x_1^i$ and $x_2^i$, then the default standardized $i$th value of the cross product is

$$\frac{x_1^ix_2^i - \text{mean}(x_1^ix_2^i)}{\text{std}(x_1^ix_2^i)}$$

If you want the cross product to be based instead on standardized variables

$$\frac{x_1^i - m^1}{s^1} \times \frac{x_2^i - m^2}{s^2}$$

where $m^k = \text{mean}(x_j^k)$ and $s^k = \text{std}(x_j^k)$ for $k = 1, 2$, then you should use the VARSCALE option in the PROC PLS statement. Standardizing the variables separately is usually a good idea, but unless the model also contains all cross products nested within each term, the resulting model may not be equivalent to a simple linear model in the same terms. To see this, note that a model involving the cross product of two standardized variables

$$\frac{x_1^i - m^1}{s^1} \times \frac{x_2^i - m^2}{s^2} = x_1^ix_2^i \frac{1}{s^1s^2} - x_1^im^2 \frac{m^2}{s^1s^2} - x_2^im^1 \frac{m^1}{s^1s^2} + \frac{m^1m^2}{s^1s^2}$$

involves both the crossproduct term and the linear terms for the unstandardized variables.
When cross validation is performed for the number of effects, there is some disagreement among practitioners as to whether each cross validation training set should be retransformed. By default, PROC PLS does so, but you can suppress this behavior by specifying the NOCVSTDIZE option in the PROC PLS statement.

**Missing Values**

By default, PROC PLS handles missing values very simply. Observations with any missing independent variables (including all class variables) are excluded from the analysis, and no predictions are computed for such observations. Observations with no missing independent variables but any missing dependent variables are also excluded from the analysis, but predictions are computed.

However, the experimental MISSING= option on the PROC PLS statement provides more sophisticated ways of modeling in the presence of missing values. If you specify MISSING=AVG or MISSING=EM, then all observations in the input data set contribute to both the analysis and the OUTPUT OUT= data set. With MISSING=AVG, the fit is computed by filling in missing values with the average of the nonmissing values for the corresponding variable. With MISSING=EM, the procedure first computes the model with MISSING=AVG, then fills in missing values by their predicted values based on that model and computes the model again. Alternatively, you can specify MISSING=EM(MAXITER=n) with a large value of n in order to perform this imputation/fit loop until convergence.

**Displayed Output**

By default, PROC PLS displays just the amount of predictor and response variation accounted for by each factor.

If you perform a cross validation for the number of factors by specifying the CV option on the PROC PLS statement, then the procedure displays a summary of the cross validation for each number of factors, along with information about the optimal number of factors.

If you specify the DETAILS option on the PROC PLS statement, then details of the fitted model are displayed for each successive factor. These details include for each number of factors

- the predictor loadings
- the predictor weights
- the response weights
- the coded regression coefficients (for METHOD = SIMPLS, PCR, or RRR)

If you specify the CENSCALE option on the PROC PLS statement, then centering and scaling information for each response and predictor is displayed.

If you specify the VARSS option on the PROC PLS statement, the procedure displays, in addition to the average response and predictor sum of squares accounted for by
each successive factor, the amount of variation accounted for in each response and predictor.

If you specify the SOLUTION option on the MODEL statement, then PROC PLS displays the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

**ODS Table Names**

PROC PLS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**Examples**

**Example 56.1. Examining Model Details**

The following example, from Umetrics (1995), demonstrates different ways to examine a PLS model. The data come from the field of drug discovery. New drugs are developed from chemicals that are biologically active. Testing a compound for biological activity is an expensive procedure, so it is useful to be able to predict biological activity from cheaper chemical measurements. In fact, computational chemistry makes it possible to calculate certain chemical measurements without even making the compound. These measurements include size, lipophilicity, and polarity at various sites on the molecule. The following statements create a data set named `penta`, which contains these data.
```sas
data penta;
  input obsnam $ S1 L1 P1 S2 L2 P2 S3 L3 P3 S4 L4 P4 S5 L5 P5 log_RAI @@;

```
You would like to study the relationship between these measurements and the activity of the compound, represented by the logarithm of the relative Bradykinin activating activity (log - RAI). Notice that these data consist of many predictors relative to the
number of observations. Partial least squares is especially appropriate in this situation as a useful tool for finding a few underlying predictive factors that account for most of the variation in the response. Typically, the model is fit for part of the data (the “training” or “work” set), and the quality of the fit is judged by how well it predicts the other part of the data (the “test” or “prediction” set). For this example, the first 15 observations serve as the training set and the rest constitute the test set (refer to Ufkes et al. 1978, 1982).

When you fit a PLS model, you hope to find a few PLS factors that explain most of the variation in both predictors and responses. Factors that explain response variation provide good predictive models for new responses, and factors that explain predictor variation are well represented by the observed values of the predictors. The following statements fit a PLS model with two factors and save predicted values, residuals, and other information for each data point in a data set named outpls.

```sas
proc pls data=ptrain nfac=2;
  model log_RAI = S1-S5 L1-L5 P1-P5;
  output out=outpls predicted = yhat1
                     yresidual = yres1
                     xresidual = xres1-xres15
                     xscore = xscri
                     yscore = yscro;
run;
```

The PLS procedure displays a table, shown in Output 56.1.1, showing how much predictor and response variation is explained by each PLS factor.

**Output 56.1.1.** Amount of Training Set Variation Explained

<table>
<thead>
<tr>
<th>Number of Extracted Factors</th>
<th>Model Effects</th>
<th>Dependent Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Current Total</td>
<td>Current Total</td>
</tr>
<tr>
<td>1</td>
<td>16.9014 16.9014</td>
<td>89.6399 89.6399</td>
</tr>
<tr>
<td>2</td>
<td>12.7721 29.6735</td>
<td>7.8368 97.4767</td>
</tr>
</tbody>
</table>

From Output 56.1.1, note that 97% of the response variation is already explained, but only 29% of the predictor variation is explained.

Partial least squares algorithms choose successive orthogonal factors that maximize the covariance between each X-score and the corresponding Y-score. For a good PLS model, the first few factors show a high correlation between the X- and Y-scores. The correlation usually decreases from one factor to the next. You can plot the X-scores versus the Y-scores for the first PLS factor using the following SAS statements.
%let ifac = 1;
data pltanno; set outpls;
  length text $ 2;
  retain function 'label' position '5' hsys '3' xsys '2' ysys '2'
    color 'blue' style 'swissb';
  text=%str(n); x=xscr&ifac; y=yscr&ifac;
  axis1 label=(angle=270 rotate=90 "Y score &ifac")
    major=(number=5) minor=none;
  axis2 label=("X-score &ifac") minor=none;
  symbol1 v=none i=none;
proc gplot data=outpls;
  plot yscr&ifac*xscr&ifac=1
    / anno=pltanno vaxis=axis1 haxis=axis2 frame cframe=ligr;
run;

By changing the macro variable `ifac` to 2 instead of 1, you can use the same statements to plot the X-scores versus the Y-scores for the second PLS factor. The resulting plots are shown in Output 56.1.2 and Output 56.1.3. The numbers on the plot represent the observation number in the `penta` data set.

**Output 56.1.2.** First X- and Y-scores for Penta-Peptide Model 1
Output 56.1.3. Second X- and Y-scores for Penta-Peptide Model 1

For this example, the figures show high correlation between X- and Y-scores for the first factor but somewhat lower correlation for the second factor.

You can also plot the X-scores against each other to look for irregularities in the data. You should look for patterns or clearly grouped observations. If you see a curved pattern, for example, you may want to add a quadratic term. Two or more groupings of observations indicate that it might be better to analyze the groups separately, perhaps by including classification effects in the model. The following SAS statements produce a plot of the first and second X-scores:

```sas
data pltanno; set outpls;
    length text $ 2;
    retain function 'label' position '5' hsys '3' xsys '2' ysys '2'
        color 'blue' style 'swissb';
    text=%str(n); x=xscr1; y=xscr2;
    axis1 label=(angle=270 rotate=90 "X score 2")
        major=(number=5) minor=none;
    axis2 label=("X-score 1") minor=none;
    symbol1 v=none i=none;
    proc gplot data=outpls;
    plot xscr2*xscr1=1
        / anno=pltanno vaxis=axis1 haxis=axis2 frame cframe=ligr;
    run;
```

The plot is shown in Output 56.1.4.
Output 56.1.4. First and Second X-scores for Penta-Peptide Model 1

This plot appears to show most of the observations close together, with a few being more spread out with larger positive X-scores for factor 2. There are no clear grouping patterns, but observation 13 stands out; note that this observation is the most extreme on all three plots so far. This run may be overly influential in the PLS analysis; thus, you should check to make sure it is reliable.

Plots of the weights give the directions toward which each PLS factor projects. They show which predictors are most represented in each factor. Those predictors with small weights in absolute value are less important than those with large weights.

You can use the DETAILS option in the PROC PLS statement to display various model details, including the X-weights. You can then use the ODS statement to send the weights to an output data set, as follows:

```latex
ods output XWeights=xweights;
proc pls data=ptrain nfac=2 details;
  model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

Once the X-weights are in a data set, you can use the following statements to plot the weights for the first two PLS factors against one another:

```latex
proc transpose data=xweights(drop=NumberOfFactors InnerRegCoef)
  out =xweights;
data xweights; set xweights;
```
Example 56.1. Examining Model Details

```sas
rename col1=w1 col2=w2;
data wt_anno; set xweights;
   length text $ 2;
   retain function ‘label’
      position ‘5’
      hsys ‘3’
      xsys ‘2’
      ysys ‘2’
      color ‘blue’
      style ‘swissb’;
   text=%str(_name_); x=w1; y=w2;
run;

axis1 label=(angle=270 rotate=90 "X weight 2")
   major=(number=5) minor=none;
axis2 label=("X-weight 1") minor=none;
symbol1 v=none i=none;
proc gplot data=xweights;
   plot w2*w1=1 / anno=wt_anno vaxis=axis1
      haxis=axis2 frame cframe=ligr;
run; quit;
```

The plot of the X-weights is shown in Output 56.1.5.

**Output 56.1.5.** First and Second X-weights for Penta-Peptide Model 1

The weights plot shows a cluster of X-variables that are weighted at nearly zero for both factors. These variables add little to the model fit, and removing them may improve the model’s predictive capability.
To explore further which predictors can be eliminated from the analysis, you can look at the regression coefficients for the standardized data. Predictors with small coefficients (in absolute value) make a small contribution to the response prediction. Another statistic summarizing the contribution a variable makes to the model is the Variable Importance for Projection (VIP) of Wold (1994). Whereas the regression coefficients represent the importance each predictor has in the prediction of just the response, the VIP represents the value of each predictor in fitting the PLS model for both predictors and response. If a predictor has a relatively small coefficient (in absolute value) and a small value of VIP, then it is a prime candidate for deletion. Wold in Umetrics (1995) considers a value less than 0.8 to be “small” for the VIP. The following statements produce coefficients and the VIP.

```/*
* Put coefficients, weights, and R**2’s into data sets.
*/
ods listing close;
ods output PercentVariation = pctvar
               XWeights = xweights
               CenScaleParms = solution;
proc pls data=ptrain nfac=2 details;
  model log_RAI = S1 L1 P1
                 S2 L2 P2
                 S3 L3 P3
                 S4 L4 P4
                 S5 L5 P5 / solution;
run;
ods listing;
/*

</table>

For this data set, the variables L1, L2, P2, S5, L5, and P5 have small absolute coefficients and small VIP. Looking back at the weights plot in Output 56.1.5, you can see that these variables tend to be the ones near zero for both PLS factors. You should consider dropping these variables from the model.
Example 56.2. Examining Outliers

This example is a continuation of Example 56.1 on page 3388.

A PLS model effectively models both the predictors and the responses. In order to check for outliers, you should, therefore, look at the Euclidean distance from each point to the PLS model in both the standardized predictors and the standardized responses. No point should be dramatically farther from the model than the rest. If there is a group of points that are all farther from the model than the rest, they may have something in common, in which case they should be analyzed separately. The following statements compute and plot these distances to the reduced model, dropping variables L1, L2, P2, P4, S5, L5, and P5:

```
proc pls data=ptrain nfac=2 noprint;
  model log_RAI = S1 P1
                S2
                S3 L3 P3
                S4 L4 ;
  output out=stdres stdxsse=stdxsse
        stddevs=stdysse;
```

```
data stdres; set stdres;
  xdist = sqrt(stdxsse);
  ydist = sqrt(stdysse);
run;
```

```
symbol1 i=needles v=dot c=blue;
proc gplot data=stdres;
  plot xdist*n=1 / cframe=ligr;
proc gplot data=stdres;
  plot ydist*n=1 / cframe=ligr;
run;
```

The plots are shown in Output 56.2.1 and Output 56.2.2.
Output 56.2.1. Distances from the X-variables to the Model (Training Set)

Output 56.2.2. Distances from the Y-variables to the Model (Training Set)
There appear to be no profound outliers in either the predictor space or the response space.

**Example 56.3. Choosing a PLS Model by Test Set Validation**

The following example demonstrates issues in spectrometric calibration. The data (Umetrics 1995) consist of spectrographic readings on 33 samples containing known concentrations of two amino acids, tyrosine and tryptophan. The spectra are measured at 30 frequencies across the overall range of frequencies. For example, **Output 56.3.1** shows the observed spectra for three samples, one with only tryptophan, one with only tyrosine, and one with a mixture of the two, all at a total concentration of $10^{-6}$.

**Output 56.3.1.** Spectra for Three Samples of Tyrosine and Tryptophan

Of the 33 samples, 18 are used as a training set and 15 as a test set. The data originally appear in McAvoy et al. (1989).

These data were created in a lab, with the concentrations fixed in order to provide a wide range of applicability for the model. You want to use a linear function of the logarithms of the spectra to predict the logarithms of tyrosine and tryptophan concentration, as well as the logarithm of the total concentration. Actually, because of the possibility of zeros in both the responses and the predictors, slightly different transformations are used. The following statements create SAS data sets containing the training and test data, named `ftrain` and `ftest`, respectively:
data ftrain;
  input obsnam $ tot tyr f1-f30 @@;
  try = tot - tyr;
  if (tyr) then tyr_log = log10(tyr); else tyr_log = -8;

The following statements fit a PLS model with 10 factors.

```plaintext
proc pls data=ftrain nfac=10;
    model tot_log tyr_log try_log = f1-f30;
run;
```

The table shown in Output 56.3.2 indicates that only three or four factors are required to explain almost all of the variation in both the predictors and the responses.

In order to choose the optimal number of PLS factors, you can explore how well models based on the training data with different numbers of factors fit the test data. To do so, use the CV=TESTSET option, with an argument pointing to the test data set `ftest`, as in the following statements:

```plaintext
proc pls data=ftrain nfac=10 cv=testset(ftest) cvtest(stat=press seed=12345);
    model tot_log tyr_log try_log = f1-f30;
run;
```

The results of the test set validation are shown in Output 56.3.3. They indicate that, although five PLS factors give the minimum predicted residual sum of squares, the residuals for four factors are insignificantly different from those for five. Thus, the smaller model is preferred.

The factor loadings show how the PLS factors are constructed from the centered and scaled predictors. For spectral calibration, it is useful to plot the loadings against the frequency. In many cases, the physical meanings that can be attached to factor loadings help to validate the scientific interpretation of the PLS model. You can use the following statements to plot the loadings for the four PLS factors against frequency.

```plaintext
ods listing close;
ods output XLoadings=xloadings;
proc pls data=ftrain nfac=4 details method=pls;
model tot_log tyr_log try_log = f1-f30;
run;
ods listing;
proc transpose data=xloadings(drop=NumberOfFactors)
out =xloadings;
```
The resulting plot is shown in **Output 56.3.4**.

**Output 56.3.4.**  Predictor Loadings Across Frequencies

![Predictor Loadings Across Frequencies](image-url)
Notice that all four factors handle frequencies below and above about 7 or 8 differently. For example, the first factor is very nearly a simple contrast between the averages of the two sets of frequencies, and the second factor appears to be a weighted sum of only the frequencies in the first set.

Chapter 57
The POWER Procedure

Overview

Power and sample size analysis enables you to optimize the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The POWER procedure performs prospective power and sample size analyses for a variety of goals, such as the following:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- conducting what-if analyses to assess sensitivity of the power or required sample size to other factors

Here prospective indicates that the analysis pertains to planning for a future study. This is in contrast to retrospective power analysis for a past study, which is not supported by the procedure.

A variety of statistical analyses are covered:

- $t$ tests for means
- equivalence tests for means
- confidence intervals for means
- tests of binomial proportions
- multiple regression
- tests of correlation and partial correlation
- one-way analysis of variance
- rank tests for comparing two survival curves

For more complex linear models, see Chapter 34, “The GLMPOWER Procedure.”

Input for PROC POWER includes the components considered in study planning:

- design
- statistical model and test
- significance level (alpha)
- surmised effects and variability
- power
- sample size
You designate one of these components by a missing value in the input, in order to identify it as the result parameter. The procedure calculates this result value over one or more scenarios of input values for all other components. Power and sample size are the most common result values, but for some analyses the result can be something else. For example, you can solve for the sample size of a single group for a two-sample $t$ test.

In addition to tabular results, PROC POWER produces graphs. You can produce the most common types of plots easily with default settings and use a variety of options for more customized graphics. For example, you can control the choice of axis variables, axis ranges, number of plotted points, mapping of graphical features (such as color, line style, symbol and panel) to analysis parameters, and legend appearance.

The POWER procedure is one of several tools available in SAS/STAT software for power and sample size analysis. PROC GLMPOWER supports more complex linear models. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures.

The following sections of this chapter describe how to use PROC POWER and discuss the underlying statistical methodology. The “Getting Started” section on page 3412 introduces PROC POWER with simple examples of power computation for a one-sample $t$ test and sample size determination for a two-sample $t$ test. The “Syntax” section on page 3420 describes the syntax of the procedure. The “Details” section on page 3488 summarizes the methods employed by PROC POWER and provides details on several special topics. The “Examples” section on page 3536 illustrates the use of the POWER procedure with several applications.

For more discussion and examples on the main concepts in power and sample size analysis, refer to Castelloe (2000), Castelloe and O’Brien (2001), Muller and Benignus (1992), O’Brien and Muller (1993), and Lenth (2001).

### Getting Started

#### Computing Power for a One-Sample $t$ Test

Suppose you want to improve the accuracy of a machine used to print logos on sports jerseys. The machine has an inherently high variability, but its horizontal alignment can be adjusted. The operator agrees to pay for a costly adjustment if you can establish a non-zero mean horizontal displacement in either direction with high confidence. You have 150 jerseys at your disposal to measure, and you want to determine your chances of a significant result (power) using a one-sample $t$ test with a 2-sided $\alpha = 0.05$.

You decide that 8 mm is the smallest displacement worth addressing. Hence, you will assume a true mean of 8 in the power computation. Experience indicates that the standard deviation is about 40.

Use the ONESAMPLEMEANS statement in the POWER procedure to compute the power. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Specify your conjectures for the mean and standard deviation...
using the MEAN= and STDDEV= options and the sample size using the NTOTAL= option. The statements required to perform this analysis are as follows:

```sas
proc power;
  onesamplemeans
    mean = 8
    ntotal = 150
    stddev = 40
    power = .;
run;
```

Default values for the TEST=, DIST=, ALPHA=, NULL=, and SIDES= options specify a 2-sided \( t \) test for a mean of 0, assuming a normal distribution with a significance level of \( \alpha = 0.05 \).

Figure 57.1 shows the output.

![The POWER Procedure](image)

**Figure 57.1.** Sample Size Analysis for One-Sample \( t \) Test

The power is about 0.68. In other words, there is about a 2/3 chance that the \( t \) test will produce a significant result demonstrating the machine’s average off-center displacement. This probability depends on the assumptions for the mean and standard deviation.

Now, suppose you want to account for some of your uncertainty in conjecturing the true mean and standard deviation by evaluating the power for four scenarios using reasonable low and high values, 5 and 10 for the mean, and 30 and 50 for the standard deviation. Also, you may be able to measure more than 150 jerseys, and you would like to know under what circumstances you could get by with fewer. You want to plot power for sample sizes between 100 and 200 to visualize how sensitive the power is to changes in sample size for these four scenarios of means and standard deviations. The following statements perform this analysis:
The new mean and standard deviation values are specified using the MEAN= and STDDEV= options in the ONESAMPLEMEANS statement. The PLOT statement with X=N produces a plot with sample size on the x-axis. (The result parameter, in this case the power, is always plotted on the other axis.) The MIN= and MAX= options in the PLOT statement determine the sample size range.

Figure 57.2 shows the output, and Figure 57.3 shows the plot.

```
proc power;
  onesamplemeans
    mean   = 5 10
    ntotal = 150
    stddev = 30 50
    power  = .;
    plot x=n min=100 max=200;
run;
```

**Figure 57.2.** Sample Size Analysis for One-Sample t Test with Input Ranges
Determining Required Sample Size for a Two-Sample t Test

Figure 57.3. Plot of Power versus Sample Size for One-Sample t Test with Input Ranges

The power ranges from about 0.23 to 0.98 for a sample size of 150 depending on the mean and standard deviation. In Figure 57.3, the line style identifies the mean, and the plotting symbol identifies the standard deviation. The locations of plotting symbols indicate computed powers; the curves are linear interpolations of these points. The plot suggests sufficient power for a mean of 10 and standard deviation of 30 (for any of the sample sizes) but insufficient power for the other three scenarios.

Determining Required Sample Size for a Two-Sample t Test

In this example you want to compare two physical therapy treatments designed to increase muscle flexibility. You need to determine the number of patients required to achieve a power of at least 0.9 to detect a group mean difference in a two-sample t test. You will use $\alpha = 0.05$ (two-tailed).

The mean flexibility with the standard treatment (as measured on a scale of 1 to 20) is well known to be about 13 and is thought to be between 14 and 15 with the new treatment. You conjecture three alternative scenarios for the means,

1. $\mu_1 = 13$, $\mu_2 = 14$
2. $\mu_1 = 13$, $\mu_2 = 14.5$
3. $\mu_1 = 13$, $\mu_2 = 15$

You conjecture two scenarios for the common group standard deviation:
1. $\sigma = 1.2$
2. $\sigma = 1.7$

You also want to try three weighting schemes:

1. equal group sizes (balanced, or 1:1)
2. twice as many patients with the new treatment (1:2)
3. three times as many patients with the new treatment (1:3)

This makes $3 \times 2 \times 3 = 18$ scenarios in all.

Use the TWOSAMPLEMEANS statement in the POWER procedure to determine the sample sizes required to give 90% power for each of these 18 scenarios. Indicate total sample size as the result parameter by specifying the NTOTAL= option with a missing value (.). Specify your conjectures for the means using the GROUPMEANS= option. Using the “matched” notation (discussed in the “Specifying Value Lists in Analysis Statements” section on page 3490), enclose the two group means for each scenario in parentheses. Use the STDDEV= option to specify scenarios for the common standard deviation. Specify the weighting schemes using the GROUPWEIGHTS= option. You could again use the matched notation. But for illustrative purposes, specify the scenarios for each group weight separately using the “crossed” notation, with scenarios for each group weight separated by a vertical bar (|). The statements that perform the analysis are as follows:

```plaintext
proc power;
   twosamplemeans
      groupmeans = (13 14) (13 14.5) (13 15)
      stddev    = 1.2 1.7
      groupweights = 1 | 1 2 3
      power      = 0.9
      ntotal     = .;
   run;
```

Default values for the TEST=, DIST=, NULLDIFF=, ALPHA=, and SIDES= options specify a 2-sided $t$ test of group mean difference equal to 0, assuming a normal distribution with a significance level of $\alpha = 0.05$. The results are shown in Figure 57.4.

Figure 57.4. Sample Size Analysis for Two-Sample t Test Using Group Means

The interpretation is that in the best-case scenario (large mean difference of 2, small standard deviation of 1.2, and balanced design), a sample size of $N = 18$ ($n_1 = n_2 = 9$) patients is sufficient to achieve a power of at least 0.9. In the worst-case scenario (small mean difference of 1, large standard deviation of 1.7, and a 1:3 unbalanced design), a sample size of $N = 164$ ($n_1 = 41, n_2 = 123$) patients is necessary. The Nominal Power of 0.9 in the Fixed Scenario Elements table represents the input target power, and the Actual Power column in the Computed N Total table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting exactly.

Note the following characteristics of the analysis, and ways you can modify them if you wish:

- The total sample sizes are rounded up to multiples of the weight sums (2 for the 1:1 design, 3 for the 1:2 design, and 4 for the 1:3 design) to ensure that each group size is an integer. To request raw fractional sample size solutions, use the NFRACTIONAL option.
- Only the group weight that varies (the one for group 2) is displayed as an
output column, while the weight for group 1 appears in the Fixed Scenario Elements table. To display the group weights together in output columns, use the matched version of the value list rather than the crossed version.

- If you can only specify differences between group means (instead of their individual values), or if you want to display the mean differences instead of the individual means, use the MEANDIFF= option instead of the GROUPMEANS= option.

The following statements implement all of these modifications.

```sas
proc power;
  twosamplemeans
    nfractional
    meandiff = 1 to 2 by 0.5
    stddev = 1.2 1.7
    groupweights = (1 1) (1 2) (1 3)
    power = 0.9
    ntotal = .;
run;
```

Figure 57.5 shows the new results.

**Figure 57.5.** Sample Size Analysis for Two-Sample t Test Using Mean Differences

Note that the Nominal Power of 0.9 applies to the raw computed sample size (Fractional N Total), and the Actual Power column applies to the rounded sample size (Ceiling N Total). Some of the adjusted sample sizes in Figure 57.5 are lower than those in Figure 57.4 because underlying group sample sizes are allowed to be fractional (for example, the first Ceiling N Total of 63 corresponding to equal group sizes of 31.5).
Syntax

The following statements are available in PROC POWER.

```plaintext
PROC POWER < options > ;
   MULTREG < options > ;
   ONECORR < options > ;
   ONESAMPLEFREQ < options > ;
   ONESAMPLEMEANS < options > ;
   ONEWAYANOVA < options > ;
   PAIREDFREQ < options > ;
   PAIREDMEANS < options > ;
   TWOSAMPLEFREQ < options > ;
   TWOSAMPLEMEANS < options > ;
   TWOSAMPLESURVIVAL < options > ;
   PLOT < plot-options > < / graph-options > ;
```

The statements in the POWER procedure consist of the PROC POWER statement, a set of analysis statements (for requesting specific power and sample size analyses), and the PLOT statement (for producing graphs). The PROC POWER statement and at least one of the analysis statements are required. The analysis statements are MULTREG, ONECORR, ONESAMPLEFREQ, ONESAMPLEMEANS, ONEWAYANOVA, PAIREDFREQ, PAIREDMEANS, TWOSAMPLEFREQ, TWOSAMPLEMEANS, and TWOSAMPLESURVIVAL.

You can use multiple analysis statements and multiple PLOT statements. Each analysis statement produces a separate sample size analysis. Each PLOT statement refers to the previous analysis statement and generates a separate graph (or set of graphs).

The name of an analysis statement describes the framework of the statistical analysis for which sample size calculations are desired. You use options in the analysis statements to identify the result parameter to compute, to specify the statistical test and computational options, and to provide one or more scenarios for the values of relevant analysis parameters.

Table 57.1 summarizes the basic functions of each statement in PROC POWER. The syntax of each statement in Table 57.1 is described in the following pages.

### Table 57.1. Statements in the POWER Procedure

<table>
<thead>
<tr>
<th>Statement</th>

</table>

See the “Summary of Analyses” section on page 3488 for a summary of the analyses available and the syntax required for them.

PROC POWER Statement

PROC POWER < options> ;

The PROC POWER statement invokes the POWER procedure. You can specify the following option.

PLOTONLY
specifies that only graphical results from the PLOT statement should be produced.

MULTREG Statement

MULTREG < options> ;

The MULTREG statement performs power and sample size analyses for Type III $F$ tests of sets of predictors in multiple linear regression, assuming either fixed or normally distributed predictors.

Summary of Options

Table 57.2 summarizes categories of options available in the MULTREG statement.

Table 57.2. Summary of Options in the MULTREG Statement

Dictionary of Options

ALPHA=number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

MODEL=keyword-list

specifies the assumed distribution of the tested predictors. MODEL=FIXED indicates a fixed predictor distribution. MODEL=RANDOM (the default) indicates a joint multivariate normal distribution for the response and tested predictors. You may use the aliases CONDITIONAL for FIXED and UNCONDITIONAL for RANDOM. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list.

FIXED fixed predictors
RANDOM random (multivariate normal) predictors

NFRAC
NFRAC

enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRAC option.
**NFULLPREDICTORS=number-list**

specifies the number of predictors in the full model, not counting the intercept. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NOINT**

specifies a no-intercept model (for both full and reduced models). By default, the intercept is included in the model. If you wish to test the intercept, you can specify the NOINT option and simply consider the intercept to be one of the predictors being tested. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NREDUCEDPREDICTORS=number-list**

specifies the number of predictors in the reduced model, not counting the intercept. This is the same as the difference between values of the NFULLPREDICTORS= and NTESTPREDICTORS= options. Note that supplying a value of 0 is the same as specifying an $F$ test of a Pearson correlation. This option cannot be used at the same time as the NTESTPREDICTORS= option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NTESTPREDICTORS=number-list**

specifies the number of predictors being tested. This is the same as the difference between values of the NFULLPREDICTORS= and NREDUCEDPREDICTORS= options. Note that supplying identical values for the NTESTPREDICTORS= and NFULLPREDICTORS= options is the same as specifying an $F$ test of a Pearson correlation. This option cannot be used at the same time as the NREDUCEDPREDICTORS= option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NTOTAL= number-list**

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=). The minimum acceptable value for the sample size depends on the MODEL=, NOINT, NFULLPREDICTORS=, NTESTPREDICTORS=, and NREDUCEDPREDICTORS= options. It ranges from $p + 1$ to $p + 3$, where $p$ is the value of the NFULLPREDICTORS option. See Table 57.26 on page 3501 for further information on minimum NTOTAL values, and see the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**OUTPUTORDER=INTERNAL**

**OUTPUTORDER=REVERSE**

**OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by
Chapter 57. The POWER Procedure

- MODEL
- NFULLPREDICTORS
- NTESTPREDICTORS
- NREDUCEDPREDICTORS
- ALPHA
- PARTIALCORR
- RSQUAREFULL
- RSQUAREREDUCED
- RSQUARED
- NTESTPREDICTORS
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the MULTREG statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the MULTREG statement.

**PARTIALCORR**=number-list

**PCORR**=number-list

specifies the partial correlation between the tested predictors and the response, adjusting for any other predictors in the model. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**POWER**= number-list

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**RSQUARED**=number-list

**RSQDIFF**=number-list

specifies the difference in $R^2$ between the full and reduced models. This is equivalent to the proportion of variation explained by the predictors you are testing. It is also equivalent to the squared semipartial correlation of the tested predictors with the response. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**RSQUAREFULL**=number-list

**RSQFULL**=number-list

specifies the $R^2$ of the full model, where $R^2$ is the proportion of variation explained by the model. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
RSQUAREREDUCED=number-list
RSQREDUCED=number-list
RSQRED=number-list

specifies the $R^2$ of the reduced model, where $R^2$ is the proportion of variation explained by the model. If the reduced model is an empty or intercept-only model (in other words, if NREDUCEDPREDICTORS = 0 or NTESTPREDICTORS = NFULLPREDICTORS), then RSQUAREREDUCED = 0 is assumed. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

TEST= TYPE3

specifies a Type III $F$ test of a set of predictors adjusting for any other predictors in the model. This is the default test option.

**Restrictions on Option Combinations**

To specify the number of predictors, use any two of these three options:

- the number of predictors in the full model (NFULLPREDICTORS=)
- the number of predictors in the reduced model (NREDUCEDPREDICTORS=)
- the number of predictors being tested (NTESTPREDICTORS=)

To specify the effect, choose one of the following parameterizations:

- partial correlation (using the PARTIALCORR= option)
- $R^2$ for the full and reduced models (using any two of RSQUAREDIF=, RSQUAREFULL=, and RSQUAREREDUCED=)

**Option Groups for Common Analyses**

This section summarizes the syntax for the common analyses supported in the MULTREG statement.

**Type III F Test of a Set of Predictors**

You can express effects in terms of partial correlation. Default values of the TEST=, MODEL=, and ALPHA= options specify a Type III $F$ test with a significance level of 0.05, assuming normally distributed predictors.

```sas
proc power;
  multreg
    model = random
    nfullpredictors = 7
    ntestpredictors = 3
    partialcorr = 0.35
    ntotal = 100
    power = .;
  run;
```

You can also express effects in terms of $R^2$. 
proc power;
  multreg
    model = fixed
    nfullpredictors = 7
    ntestpredictors = 3
    rsquarefull = 0.9
    rsquarediff = 0.1
    ntotal = .
    power = 0.9;
run;

**ONECORR Statement**

**ONECORR < options > ;**

The ONECORR statement performs power and sample size analyses for tests of simple and partial Pearson correlation between two variables. Both Fisher’s $z$ test and the $t$ test are supported.

**Summary of Options**

Table 57.4 summarizes categories of options available in the ONECORR statement.

**Table 57.4. Summary of Options in the ONECORR Statement**

<table>

<td>NTOTAL = .</td>
</tr>
</tbody>
</table>
**Dictionary of Options**

**ALPHA=number-list**

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**CORR=number-list**

specifies the correlation between two variables, possibly adjusting for other variables as determined by the NPARTIALVARS= option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**DIST=FISHERZ**

**DIST=T**

specifies the underlying distribution assumed for the test statistic. FISHERZ corresponds to Fisher’s $z$ normalizing transformation of the correlation coefficient. T corresponds to the $t$ transformation of the correlation coefficient. Note that DIST=T is equivalent to analyses in the MULTREG statement with NTESTPREDICTORS=1. The default value is FISHERZ.

**MODEL=keyword-list**

specifies the assumed distribution of the first variable when DIST=T. The second variable is assumed to have a normal distribution. MODEL=FIXED indicates a fixed distribution. MODEL=RANDOM (the default) indicates a joint bivariate normal distribution with the second variable. You may use the aliases CONDITIONAL for FIXED and UNCONDITIONAL for RANDOM. This option can only be used for DIST=T. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list.

- FIXED fixed variables
- RANDOM random (bivariate normal) variables

**NFRATIONAL**

**NFRAC**

enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRATIONAL option.

**NPARTIALVARS=number-list**

**NPVARS=number-list**

specifies the number of variables adjusted for in the correlation between the two primary variables. The default value is 0, corresponding to a simple correlation. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NTOTAL= number-list**

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). Values for the sample size must be at least $p + 3$ when DIST=T.
and MODEL=CONDITIONAL, and at least \( p + 4 \) when either DIST=FISHER or when DIST=T and MODEL=UNCONDITIONAL, where \( p \) is the value of the NPARTIALV ARS option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the \textit{number-list}.

\textbf{NULLCORR=\textit{number-list}}

\textbf{NULLC=\textit{number-list}}

specifies the null value of the correlation. The default value is 0. This option can only be used with the DIST=FISHERZ analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the \textit{number-list}.

\textbf{OUTPUTORDER=INTERNAL}

\textbf{OUTPUTORDER=REVERSE}

\textbf{OUTPUTORDER=SYNTAX}

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- MODEL
- SIDES
- NULL
- ALPHA
- NPARTIALV ARS
- CORR
- NTOTAL
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONECORR statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONECORR statement.

\textbf{POWER=\textit{number-list}}

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the \textit{number-list}.

\textbf{TEST= PEARSON}

specifies a test of the Pearson correlation coefficient between two variables, possibly adjusting for other variables. This is the default test option.

\textbf{Option Groups for Common Analyses}

This section summarizes the syntax for the common analyses supported in the ONECORR statement.
Fisher’s z test for Pearson Correlation

Default values of \text{TEST=PEARSON}, \text{ALPHA=.05}, \text{SIDES=2}, and \text{NPARTIALVARS=0} are assumed.

\begin{verbatim}
proc power;
   onecorr dist=fisherz
   null = 0.15
   corr = 0.35
   ntotal = 180
   power = .
run;
\end{verbatim}

t test for Pearson Correlation

Default values of \text{TEST=PEARSON}, \text{MODEL=RANDOM}, \text{ALPHA=.05}, and \text{SIDES=2} are assumed.

\begin{verbatim}
proc power;
   onecorr dist=t
   npartialvars = 4
   corr = 0.45
   ntotal = .
   power = 0.85
run;
\end{verbatim}

\section*{ONESAMPLEFREQ Statement}

\texttt{ONESAMPLEFREQ < options > ;}

The ONESAMPLEFREQ statement performs power and sample size analyses for exact and approximate tests of a single binomial proportion.

\section*{Summary of Options}

Table 57.6 summarizes categories of options available in the ONESAMPLEFREQ statement.

</tbody>
</table>

**Dictionary of Options**

**ALPHA=** *number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**METHOD=** *EXACT*

**METHOD=** *NORMAL*

specifies the computational method. METHOD=EXACT (the default) computes exact results using the binomial distribution. METHOD=NORMAL computes approximate results using the normal approximation to the binomial distribution.

**NFRACTIONAL**

**NFRAC**

enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

**NTOTAL=** *number-list*

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**NULLPROPORTION=** *number-list*

**NULLP=** *number-list*

specifies the null proportion. A value of 0.5 corresponds to the sign test. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**OUTPUTORDER=** *INTERNAL*

**OUTPUTORDER=** *REVERSE*

**OUTPUTORDER=** *SYNTAX*

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by
• SIDES
• NULLPROPORTION
• ALPHA
• PROPORTION
• NTOTAL
• POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONESAMPLEFREQ statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONESAMPLEFREQ statement.

POWER= number-list
specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

PROPORTION=number-list
P=number-list
specifies the binomial proportion, that is, the expected proportion of successes in the hypothetical binomial trial. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

SIDES=keyword-list
specifies the number of sides (or tails) and direction of the statistical test. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list. Valid keywords are

1 1-sided with alternative hypothesis in same direction as effect
2 2-sided
U upper 1-sided with alternative greater than null value
L lower 1-sided with alternative less than null value

The default value is 2.

TEST= ADJZ
TEST= EXACT
TEST= Z
specifies the statistical analysis. TEST=ADJZ specifies a normal-approximate z test with continuity adjustment. TEST=EXACT (the default) specifies the exact binomial test. TEST=Z specifies a normal-approximate z test without any continuity adjustment, which is the same as the chi-square test when SIDES=2.
Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the ONESAMPLEFREQ statement.

Exact Test of a Binomial Proportion

Defaults for the SIDES= and ALPHA= options specify a 2-sided test with a 0.05 significance level.

```
proc power;
    onefreq test=binomial
        nullproportion = 0.2
        proportion = 0.3
        ntotal = 100
        power = .;
run;
```

z Test

Defaults for the SIDES= and ALPHA= options specify a 2-sided test with a 0.05 significance level.

```
proc power;
    onefreq test=z
        nullproportion = 0.8
        proportion = 0.85
        sides = u
        ntotal = .
        power = .9;
run;
```

z Test with Continuity Adjustment

Defaults for the SIDES= and ALPHA= options specify a 2-sided test with a 0.05 significance level.

```
proc power;
    onefreq test=adjz
        nullproportion = 0.15
        proportion = 0.1
        sides = l
        ntotal = .
        power = .9;
run;
```

ONESAMPLEMEANS Statement

```
ONESAMPLEMEANS < options >;
```

The ONESAMPLEMEANS statement performs power and sample size analyses for t tests, equivalence tests, and confidence interval precision involving one sample.
Summary of Options

Table 57.8 summarizes categories of options available in the ONESAMPLEMEANS statement.

Dictionary of Options

**ALPHA=** number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**CI**

**CI=** T

specifies an analysis of precision of the confidence interval for the mean. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the confidence interval will be at most the value specified by the **HALFWIDTH=** option. If neither the **CI=** option nor the **TEST=** option is used, the default is **TEST=T**.

**CV=** number-list

specifies the coefficient of variation, defined as the ratio of the standard deviation to the mean. You can use this option only with **DIST=LOGNORMAL**. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**DIST=** LOGNORMAL

**DIST=** NORMAL

specifies the underlying distribution assumed for the test statistic. **NORMAL** corresponds to the normal distribution, and **LOGNORMAL** corresponds to the lognormal distribution. The default value is **NORMAL**.

**HALFWIDTH=** number-list

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can only be used with the **CI=** T analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**LOWER=** number-list

specifies the lower equivalence bound for the mean. This option can only be used with the **TEST=EQUIV** analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**MEAN=** number-list

specifies the mean, in the original scale. The mean is arithmetic if **DIST=NORMAL** and geometric if **DIST=LOGNORMAL**. This option can only be used with the **TEST=T** and **TEST=EQUIV** analyses. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NFRACTIONAL**

**NFRAC**

enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the **NFRACTIONAL** option.
NTOTAL= number-list
specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

NULLMEAN=number-list
NULLM=number-list
specifies the null mean, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). The default value is 0 when DIST=NORMAL and 1 when DIST=LOGNORMAL. This option can only be used with the TEST=T analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

OUTPUTORDER=INTERNAL
OUTPUTORDER=REVERSE
OUTPUTORDER=SYNTAX
controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLMEAN
- LOWER
- UPPER
- ALPHA
- MEAN
- HALFWIDTH
- STDDEV
- CV
- NTOTAL
- POWER
- PROBTYPE
- PROBWIDTH

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONESAMPLEMEANS statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONESAMPLEMEANS statement.

POWER= number-list
specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option can only be used with the TEST=T and TEST=EQUIV analyses. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
PROBTYPE=keyword-list
specifies the type of probability for the PROBWIDTH= option. A value of CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option, given that the true mean is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option. You may use the alias GIVENVALIDITY for CONDITIONAL. The PROBTYPE= option can only be used with the CI=T analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list.

CONDITIONAL width probability conditional on interval containing the mean
UNCONDITIONAL unconditional width probability

PROBWIDTH=number-list
specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the HALFWIDTH= option. A missing value (PROBWIDTH=.) requests a solution for this probability. The type of probability is controlled with the PROBTYPE= option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can only be used with the CI=T analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

SIDES=keyword-list
specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list. Valid keywords and their interpretation for the TEST= analyses are

1 1-sided with alternative hypothesis in same direction as effect
2 2-sided
U upper 1-sided with alternative greater than null value
L lower 1-sided with alternative less than null value

For confidence intervals, SIDES=U refers to an interval between the lower confidence limit and infinity, and SIDES=L refers to an interval between negative infinity and the upper confidence limit. For both of these cases and SIDES=1, the confidence interval computations are equivalent. The SIDES= option can only be used with the TEST=T and CI=T analyses. The default value is 2.

STDDEV=number-list
STD=number-list
specifies the standard deviation. You can use this option only with DIST=NORMAL. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
ONESAMPLEMEANS Statement ♦ 3437

TEST
TEST=EQUIV
TEST=T

specifies the statistical analysis. TEST=EQUIV specifies an equivalence test of the mean using a two one-sided tests (TOST) analysis (Schuirmann 1987). TEST or TEST=T (the default) specifies a $t$ test on the mean. If neither the TEST= option nor the CI= option is used, the default is TEST=T.

UPPER=number-list

specifies the upper equivalence bound for the mean, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (using the TEST= option)
- confidence interval precision (using the CI= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the ONESAMPLEMEANS statement.

One-sample t Test

Default values for the DIST=, SIDES=, NULLMEAN=, and ALPHA= options specify a 2-sided test for zero mean with a normal distribution and a significance level of 0.05.

```
proc power;
   onenomeans test=t
   mean = 7
   stddev = 3
   ntotal = 50
   power = .;
run;
```

One-sample t Test with Lognormal Data

Default values for the SIDES=, NULLMEAN=, and ALPHA= options specify a 2-sided test for unit mean with a significance level of 0.05.

```
proc power;
   onenomeans test=t dist=lognormal
   mean = 7
   cv = 0.8
   ntotal = .
   power = 0.9;
run;
```
Equivalence Test for Mean of Normal Data
Default values for the DIST= and ALPHA= options specify a normal distribution and a significance level of 0.05.

```proc power;
   onesamplemeans test=equiv
      lower = 2
      upper = 7
      mean = 4
      stddev = 3
      ntotal = 100
      power = .;
run;
```

Equivalence Test for Mean of Lognormal Data
The default of ALPHA=0.05 specifies a significance level of 0.05.

```proc power;
   onesamplemeans test=equiv dist=lognormal
      lower = 1
      upper = 5
      mean = 3
      cv = 0.6
      ntotal = .
      power = 0.85;
run;
```

Confidence Interval for Mean
By default CI=T analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean. The defaults of SIDES=2 and ALPHA=0.05 specify a 2-sided interval with a confidence level of 0.95.

```proc power;
   onesamplemeans ci = t
      halfwidth = 14
      stddev = 8
      ntotal = 50
      probwidth = .;
run;
```

ONEWAYANOVA Statement

```ONEWAYANOVA < options >;
```
The ONEWAYANOVA statement performs power and sample size analyses for one-degree-of-freedom contrasts and the overall $F$ test in one-way analysis of variance.
Summary of Options

Table 57.10 summarizes categories of options available in the ONEWAYANOVA statement.

Dictionary of Options

**ALPHA=** number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**CONTRAST=** (values) < ... values >

specifies coefficients for single-degree-of-freedom hypothesis tests. You must provide a coefficient for every mean appearing in the GROUPMEANS= option. Specify
multiple contrasts either with additional sets of coefficients or with additional CONTRAST= options. For example, you can specify two different contrasts of five means using

\[
\text{CONTRAST} = (1 \ -1 \ 0 \ 0 \ 0) \ (1 \ 0 \ -1 \ 0 \ 0)
\]

GROUPMEANS=grouped-number-list
GMEANS=grouped-number-list
specifies the group means. This option is used to implicitly set the number of groups. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

GROUPNS= grouped-number-list
GNS= grouped-number-list
specifies the group sample sizes. The number of groups represented must be the same as with the GROUPMEANS= option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

GROUPWEIGHTS= grouped-number-list
GWEIGHTS= grouped-number-list
specifies the sample size allocation weights for the groups. This option controls how the total sample size is divided between the groups. Each set of values across all groups represents relative allocation weights. Additionally, if the NFRACTIONAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). The number of groups represented must be the same as with the GROUPMEANS= option. Values must be integers unless the NFRACTIONAL option is used. The default value is 1 for each group, amounting to a balanced design. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

NFRACTIONAL
NFRAC
enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

NPERGROUP= number-list
NPERG= number-list
specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

NTOTAL= number-list
specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
**NULLCONTRAST=** `number-list`  
**NULLC=** `number-list`  

specifies the null value of the contrast. The default value is 0. This option can only be used with the TEST=CONTRAST analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**OUTPUTORDER=** `INTERNAL`  
**OUTPUTORDER=** `REVERSE`  
**OUTPUTORDER=** `SYNTAX`  

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- CONTRAST
- SIDES
- NULLCONTRAST
- ALPHA
- GROUPMEANS
- STDDEV
- GROUPWEIGHTS
- NTOTAL
- NPERGROUP
- GROUPNS
- POWER

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the ONEWAYANOVA statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the ONEWAYANOVA statement.

**POWER=** `number-list`  

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**SIDES=** `keyword-list`  

specifies the number of sides (or tails) and direction of the statistical test. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `keyword-list`. Valid keywords are

1 1-sided with alternative hypothesis in same direction as effect  
2 2-sided  
U upper 1-sided with alternative greater than null value
This option can only be used with the TEST=CONTRAST analysis. The default value is 2.

`STDDEV=number-list`
`STD=number-list`

specifies the error standard deviation. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**TEST= CONTRAST**
**TEST= OVERALL**

specifies the statistical analysis. TEST=CONTRAST specifies a one-degree-of-freedom test of a contrast of means. The test is the usual $F$ test for the 2-sided case and the usual $t$ test for the 1-sided case. TEST=OVERALL specifies the overall $F$ test of equality of all means. The default is TEST=CONTRAST if the CONTRAST= option is used, and TEST=OVERALL otherwise.

**Restrictions on Option Combinations**

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

**Option Groups for Common Analyses**

This section summarizes the syntax for the common analyses supported in the ONEWAYANOVA statement.

**One-Degree-of-Freedom Contrast**

You can use the NPERGROUP= option in a balanced design. Default values for the SIDES=, NULLCONTRAST=, and ALPHA= options specify a 2-sided test for a contrast value of 0 with a significance level of 0.05.

```plaintext
class proc power;
   onewayanova test=contrast
      contrast = (1 0 -1)
      groupmeans = 3 | 7 | 8
      stddev = 4
      npergroup = 50
      power = .;
   run;
```

You can also specify an unbalanced design with the NTOTAL= and GROUPWEIGHTS= options.
proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    groupweights = (1 2 2)
    ntotal = .
    power = 0.9;
run;

Another way to specify the sample sizes is with the GROUPN= option.

proc power;
  onewayanova test=contrast
    contrast = (1 0 -1)
    groupmeans = 3 | 7 | 8
    stddev = 4
    groupns = (20 40 40)
    power = .;
run;

Overall F Test

The default of ALPHA=0.05 specifies a significance level of 0.05.

proc power;
  onewayanova test=overall
    groupmeans = 3 | 7 | 8
    stddev = 4
    npergroup = 50
    power = .;
run;

PAIREDFREQ Statement

PAIREDFREQ < options > ;

The PAIREDFREQ statement performs power and sample size analyses for McNemar’s test for paired proportions.

Dictionary of Options

**ALPHA=** number-list

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**DISCPROPORTIONS=** grouped-number-list

**DISCPS=** grouped-number-list

specifies the two discordant proportions, $p_{10}$ and $p_{01}$. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

**DISCPROPDIFF=** number-list

**DISCPDIFF=** number-list

specifies the difference $p_{01} - p_{10}$ between discordant proportions. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
DISCPROPRATIO=number-list
DISCPRATIO=number-list
specifies the ratio $p_{01}/p_{10}$ of discordant proportions. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

DIST=EXACT_COND
DIST= NORMAL
specifies the underlying distribution assumed for the test statistic. EXACT_COND corresponds to the exact conditional test, based on the exact binomial distribution of the two types of discordant pairs given the total number of discordant pairs. NORMAL corresponds to the conditional test based on the normal approximation to the binomial distribution of the two types of discordant pairs given the total number of discordant pairs. The default value is EXACT_COND.

METHOD=CONNOR
METHOD=EXACT
METHOD=MIE TTINEN
specifies the computational method. METHOD=EXACT (the default) uses the exact binomial distributions of the total number of discordant pairs and the two types of discordant pairs. METHOD=CONNOR uses an approximation from Connor (1987), and METHOD=MIE TTINEN uses an approximation from Miettinen (1968). The CONNOR and MIE TTINEN methods are valid only for DIST=NORMAL.

NFRAC
NFRAC
enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRAC option. This option cannot be used with METHOD=EXACT.

NPAIRS= number-list
specifies the total number of proportion pairs (concordant and discordant) or requests a solution for the number of pairs with a missing value (NPAIRS=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

NULLDISCPROPRATIO=number-list
NULLDISCPRATIO=number-list
NULLRATIO=number-list
NULLR= number-list
specifies the null value of the ratio of discordant proportions. The default value is 1. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

OUTPUTORDER=INTERNAL
OUTPUTORDER= REVERSE
OUTPUTORDER= SYNTAX
controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by
The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the PAIREDFREQ statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the PAIREDFREQ statement.

**POWER**\(^{=}\) number-list
specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**REFPROPORTION**\(^{=}\)number-list
**REFP**\(^{=}\)number-list
specifies the reference discordant proportion \(p_{10}\). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**SIDES**\(^{=}\)keyword-list
specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list. Valid keywords and their interpretation are

1. 1-sided with alternative hypothesis in same direction as effect
2. 2-sided
U. upper 1-sided with alternative greater than null value
L. lower 1-sided with alternative less than null value

The default value is 2.

**TEST**\(^{=}\)MCNEMAR
specifies the McNemar test of paired proportions. This is the default test option.
**TOTALPROPDISC**=number-list
**TOTALPDISC**=number-list
**PDISC**=number-list

specifies the sum of the two discordant proportions, \( p_{10} + p_{01} \). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**Restrictions on Option Combinations**

To specify the proportions, choose one of the following parameterizations:

- discordant proportions (using the DISCPROPORTIONS= option)
- difference and sum of discordant proportions (using the DISCPROPORTIONDIFF= and TOTALPROPDISC= options)
- ratio of discordant proportions and reference discordant proportion (using the DISCPROPRATIO= and REFPROPORTION= options)

**Option Groups for Common Analyses**

This section summarizes the syntax for the common analyses supported in the PAIREDFREQ statement.

**McNemar Exact Conditional Test**

You can express effects in terms of the individual discordant proportions. Default values for the TEST=, SIDES=, ALPHA=, and NULLDISCPROPRA TIO= options specify a 2-sided McNemar test for no effect with a significance level of 0.05.

```plaintext
proc power;
    pairedfreq dist=exact_cond
discproportions = 0.15 | 0.45
    npairs = 80
    power = .;
run;
```

You can also express effects in terms of the difference and sum of discordant proportions.

```plaintext
proc power;
    pairedfreq dist=exact_cond
discpropdiff = 0.3
totalpropdisc = 0.6
    npairs = .
    power = 0.9;
run;
```

You can also express effects in terms of the ratio of discordant proportions and the denominator of the ratio.
proc power;
   pairedfreq dist=exact_cond
discpropratio = 3
   refproportion = 0.15
   npairs = 80
   power = .;
run;

McNemar Normal Approximation Test

The default value for the METHOD= option specifies an exact sample size computation. Default values for the TEST=, SIDES=, ALPHA=, and NULLDISCPROPRATIO= options specify a 2-sided McNemar test for no effect with a significance level of 0.05.

proc power;
   pairedfreq dist=normal
discproportions = 0.15 | 0.45
   npairs = .
   power = .9;
run;

PAIREDMEANS Statement

PAIREDMEANS < options > ;

The PAIREDMEANS statement performs power and sample size analyses for t tests, equivalence tests, and confidence interval precision involving paired samples.

Summary of Options

Table 57.14 summarizes categories of options available in the PAIREDMEANS statement.

Dictionary of Options

ALPHA=number-list
specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

CI

CI=DIFF
specifies an analysis of precision of the confidence interval for the mean difference. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the observed confidence interval will be at most the value specified by the
HALFWIDTH= option. If neither the CI= option nor the TEST= option is used, the default is TEST=DIFF.

**CORR=** number-list

specifies the correlation between members of a pair. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**CV=** number-list

specifies the coefficient of variation assumed to be common to both members of a pair. The coefficient of variation is defined as the ratio of the standard deviation to the mean. You can use this option only with DIST=LOGNORMAL. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**DIST=** LOGNORMAL

DIST= NORMAL

specifies the underlying distribution assumed for the test statistic. NORMAL corresponds the normal distribution, and LOGNORMAL corresponds to the log-normal distribution. The default value (also the only acceptable value in each case) is NORMAL for TEST=DIFF, TEST=EQUIV_DIFF, and CI=DIFF; and LOGNORMAL for TEST=RATIO and TEST=EQUIV_RATIO.

**HALFWIDTH=** number-list

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can only be used with the CI=DIFF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**LOWER=** number-list

specifies the lower equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**MEANDIFF=** number-list

specifies the mean difference, defined as the mean of the difference between the second and first members of a pair, $\mu_2 - \mu_1$. This option can only be used with the TEST=DIFF and TEST=EQUIV_DIFF analyses. When TEST=EQUIV_DIFF, the mean difference is interpreted as the treatment mean minus the reference mean. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**MEANRATIO=** number-list

specifies the geometric mean ratio, defined as $\gamma_2/\gamma_1$. This option can only be used with the TEST=RATIO and TEST=EQUIV_RATIO analyses. When TEST=EQUIV_RATIO, the mean ratio is interpreted as the treatment mean divided by the reference mean. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
**NFRACTIONAL**

**NFRAC**

enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

**NPAIRS** = *number-list*

specifies the number of pairs or requests a solution for the number of pairs with a missing value (NPAIRS=). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**NULLDIFF** = *number-list*

**NULLD** = *number-list*

specifies the null mean difference. The default value is 0. This option can only be used with the TEST=DIF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**NULLRATIO** = *number-list*

**NULLR** = *number-list*

specifies the null mean ratio. The default value is 1. This option can only be used with the TEST=RATIO analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**OUTPUTORDER** = INTERNAL

**OUTPUTORDER** = REVERSE

**OUTPUTORDER** = SYNTAX

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLDIFF
- NULLRATIO
- LOWER
- UPPER
- ALPHA
- PAIREDFREQ
- MEANDIFF
- MEANRATIO
- HALFWIDTH
- STDDEV
- PAIREDSTDDEVS
- CV
- PAIREDCVS
- CORR
- NPAIRS
The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the PAIREDMEANS statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the PAIREDMEANS statement.

**PAIREDCVS=** `grouped-number-list`

specifies the coefficient of variation for each member of a pair. Unlike the CV= option, the PAIREDCVS= option supports different values for each member of a pair. This option can only be used with DIST=LOGNORMAL. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `grouped-number-list`.

**PAIREDMEANS=** `grouped-number-list`
**PMEANS=** `grouped-number-list`

specifies the two paired means, in the original scale. The means are arithmetic if DIST=NORMAL and geometric if DIST=LOGNORMAL. This option cannot be used with the CI=DIFF analysis. When TEST=EQUIV_DIFF, the means are interpreted as the reference mean (first) and the treatment mean (second). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `grouped-number-list`.

**PAIREDSTDDEVS=** `grouped-number-list`
**PAIREDSTDS=** `grouped-number-list`
**PSTDDEVS=** `grouped-number-list`
**PSTDS=** `grouped-number-list`

specifies the standard deviation of each member of a pair. Unlike the STDDEV= option, the PAIREDSTDDEVS= option supports different values for each member of a pair. This option can only be used with DIST=NORMAL. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `grouped-number-list`.

**POWER=** `number-list`

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option cannot be used with the CI=DIFF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**PROBTYPE=** `keyword-list`

specifies the type of probability for the PROBWIDTH= option. A value of CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option, given that the true mean difference is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the HALFWIDTH= option.
You may use the alias GIVENVALIDITY for CONDITIONAL. The PROBTYPE= option can only be used with the CI=DIFF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list.

**CONDITIONAL**  width probability conditional on interval containing the mean

**UNCONDITIONAL**  unconditional width probability

**PROBWIDTH=** *number-list*

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the HALFWIDTH= option. A missing value (PROBWIDTH=.) requests a solution for this probability. The type of probability is controlled with the PROBTYPE= option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can only be used with the CI=DIFF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**SIDES=** *keyword-list*

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *keyword-list*. Valid keywords and their interpretation for the TEST= analyses are

<table>
<thead>
<tr>
<th>SIDES</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1-sided with alternative hypothesis in same direction as effect</td>
</tr>
<tr>
<td>2</td>
<td>2-sided</td>
</tr>
<tr>
<td>U</td>
<td>upper 1-sided with alternative greater than null value</td>
</tr>
<tr>
<td>L</td>
<td>lower 1-sided with alternative less than null value</td>
</tr>
</tbody>
</table>

For confidence intervals, SIDES=U refers to an interval between the lower confidence limit and infinity, and SIDES=L refers to an interval between negative infinity and the upper confidence limit. For both of these cases and SIDES=1, the confidence interval computations are equivalent. The SIDES= option cannot be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. The default value is 2.

**STDDEV=** *number-list*

**STD=** *number-list*

specifies the standard deviation assumed to be common to both members of a pair. This option can only be used with DIST=NORMAL. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*. 
TEST
TEST=DIFF
TEST=EQUIV_DIF
TEST=EQUIV_RATI
TEST=RATI

specifies the statistical analysis. TEST or TEST=DIFF (the default) specifies a paired
$t$ test on the mean difference. TEST=EQUIV_DIF specifies an additive equivalence
test of the mean difference using a two one-sided tests (TOST) analysis (Schuirmann
1987). TEST=EQUIV_RATI specifies a multiplicative equivalence test of the mean
ratio using a TOST analysis. TEST=RATI specifies a paired $t$ test on the geometric
mean ratio. If neither the TEST= option nor the CI= option is used, the default is
TEST=DIFF.

UPPER=number-list

specifies the upper equivalence bound for the mean difference or mean ratio, in the
original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can
only be used with the TEST=EQUIV_DIF and TEST=EQUIV_RATI analyses. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for
information on specifying the number-list.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (using the TEST= option)
- confidence interval precision (using the CI= option)

To specify the means, choose one of the following parameterizations:

- individual means (using the PAIREDMEANS= option)
- mean difference (using the MEANDIFF= option)
- mean ratio (using the MEANRATIO= option)

To specify the coefficient of variation, choose one of the following parameterizations:

- common coefficient of variation (using the CV= option)
- individual coefficients of variation (using the PAIREDCVS= option)

To specify the standard deviation, choose one of the following parameterizations:

- common standard deviation (using the STDDEV= option)
- individual standard deviations (using the PAIREDSTDDEV= option)
Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the PAIREDMEANS statement.

Paired t Test

You can express effects in terms of the mean difference and variability in terms of a correlation and common standard deviation. Default values for the DIST=, SIDES=, NULLDIFF=, and ALPHA= options specify a 2-sided test for no difference with a normal distribution and a significance level of 0.05.

```
proc power;
    pairedmeans test=diff
        meandiff = 7
        corr = 0.4
        stddev = 12
        npairs = 50
        power = .;
    run;
```

You can also express effects in terms of individual means and variability in terms of correlation and individual standard deviations.

```
proc power;
    pairedmeans test=diff
        pairedmeans = 8 | 15
        corr = 0.4
        pairedstddevs = (7 12)
        npairs = .
        power = 0.9;
    run;
```

Paired t Test of Mean Ratio with Lognormal Data

You can express variability in terms of correlation and a common coefficient of variation. Defaults for the DIST=, SIDES=, NULLRATIO= and ALPHA= options specify a 2-sided test of mean ratio = 1 assuming a lognormal distribution and a significance level of 0.05.

```
proc power;
    pairedmeans test=ratio
        meanratio = 7
        corr = 0.3
        cv = 1.2
        npairs = 30
        power = .;
    run;
```

You can also express variability in terms of correlation and individual coefficients of variation.
Chapter 57. The POWER Procedure

```latex
proc power;
pairedmeans test=ratio
  meanratio = 7
corr = 0.3
  pairedcvs = 0.8 | 0.9
  npairs = 30
  power = .;
run;
```

**Additive Equivalence Test for Mean Difference with Normal Data**

Default values for the DIST= and ALPHA= options specify a normal distribution and a significance level of 0.05.

```latex
proc power;
pairedmeans test=equiv_diff
  lower = 2
  upper = 5
  meandiff = 4
corr = 0.2
stddev = 8
  npairs = .
power = 0.9;
run;
```

**Multiplicative Equivalence Test for Mean Ratio with Lognormal Data**

Default values for the DIST= and ALPHA= options specify a lognormal distribution and a significance level of 0.05.

```latex
proc power;
pairedmeans test=equiv_ratio
  lower = 3
  upper = 7
  meanratio = 5
corr = 0.2
cv = 1.1
  npairs = 50
  power = .;
run;
```

**Confidence Interval for Mean Difference**

By default CI=DIFF analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean difference. The defaults of SIDES=2 and ALPHA=0.05 specify a 2-sided interval with a confidence level of 0.95.
TWOSAMPLEFREQ Statement

TWOSAMPLEFREQ < options > ;

The TWOSAMPLEFREQ statement performs power and sample size analyses for tests of two independent proportions. Pearson’s chi-square, Fisher’s exact, and likelihood ratio chi-square tests are supported.

Summary of Options

Table 57.16 summarizes categories of options available in the TWOSAMPLEFREQ statement.

Dictionary of Options

**ALPHA=number-list**

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual \(0.05 \times 100\% = 5\%\) level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**GROUPPROPORTIONS=grouped-number-list**

**GPROPORTIONS=grouped-number-list**

**GROUPPS=grouped-number-list**

**GPS=grouped-number-list**

specifies the two independent proportions, \(p_1\) and \(p_2\). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

**GROUPNS=grouped-number-list**

**GNS=grouped-number-list**

specifies the two group sample sizes or requests a solution for one group sample size given the other. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

**GROUPWEIGHTS=grouped-number-list**

**GWEIGHTS=grouped-number-list**

specifies the sample size allocation weights for the two groups, or requests a solution for one group weight given the other. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the NFRATIONAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the NFRATIONAL option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.
**NFRACTIONAL**

NFRACTIONAL enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

**NPERGROUP= number-list**

NPERGROUP= number-list specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NTOTAL= number-list**

NTOTAL= number-list specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NULLODDSRATIO=number-list**

NULLODDSRATIO=number-list specifies the null odds ratio. The default value is 1. This option can only be used along with the ODDSRA TIO= option in the TEST=PCHI analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NULLPROPORTIONDIFF=number-list**

NULLPROPORTIONDIFF=number-list specifies the null proportion difference. The default value is 0. This option can only be used along with the GROUPPROPORTIONS= or PROPORTIONDIFF= option in the TEST=PCHI analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**NULLRELATIVERISK=number-list**

NULLRELATIVERISK=number-list specifies the null relative risk. The default value is 1. This option can only be used along with the RELATIVERISK= option in the TEST=PCHI analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**ODDSRATIO=number-list**

ODDSRATIO=number-list specifies the odds ratio \( \frac{\left[p_2/(1-p_2)\right]}{\left[p_1/(1-p_1)\right]} \). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**OUTPUTORDER=INTERNAL**

OUTPUTORDER=REVERSE

OUTPUTORDER=SYNTAX controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by
The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the TWOSAMPLEFREQ statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the TWOSAMPLEFREQ statement.

**POWER=** number-list

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**PROPORTIONDIFF=** number-list

**PDIFF=** number-list

specifies the proportion difference \( p_2 - p_1 \). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**REFPROPORTION=** number-list

**REFP=** number-list

specifies the reference proportion \( p_1 \). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**RELATIVERISK=** number-list

**RR=** number-list

specifies the relative risk \( p_2/p_1 \). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
SIDES=keyword-list

specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list. Valid keywords and their interpretation are

1 1-sided with alternative hypothesis in same direction as effect
2 2-sided
U upper 1-sided with alternative greater than null value
L lower 1-sided with alternative less than null value

The default value is 2.

TEST=FISHER
TEST=LRCHI
TEST=PCHI

specifies the statistical analysis. TEST=FISHER specifies Fisher’s exact test. TEST=LRCHI specifies the likelihood ratio chi-square test. TEST=PCHI (the default) specifies Pearson’s chi-square test.

Restrictions on Option Combinations

To specify the proportions, choose one of the following parameterizations:

- individual proportions (using the GROUPPROPORTIONS= option)
- difference between proportions and reference proportion (using the PROPORTIONDIFF and REFPROPORTION= options)
- odds ratio and reference proportion (using the ODDSRATIO= and REFPROPORTION= options)
- relative risk and reference proportion (using the RELATIVERISK= and REFPROPORTION= options)

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the TWOSAMPLEFREQ statement.
Pearson Chi-square Test for Two Proportions

You can use the NPERGROUP= option in a balanced design and express effects in terms of the individual proportions. Default values for the SIDES= and ALPHA= options specify a 2-sided test with a significance level of 0.05.

```sas
proc power;
  twosamplefreq test=pchi
    groupproportions = (.15 .25)
    nullproportiondiff = .03
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design using the NTOTAL= and GROUPWEIGHTS= options and express effects in terms of the odds ratio. The default value of the NULLODDSRATIO= option specifies a test of no effect.

```sas
proc power;
  twosamplefreq test=pchi
    oddsratio = 2.5
    refproportion = 0.3
    groupweights = (1 2)
    ntotal = .
    power = 0.8;
run;
```

You can also specify sample sizes with the GROUPNS= option and express effects in terms of relative risks. The default value of the NULLRELATIVERISK= option specifies a test of no effect.

```sas
proc power;
  twosamplefreq test=pchi
    relativerisk = 1.5
    refproportion = 0.2
    groupns = 40 | 60
    power = .;
run;
```

You can also express effects in terms of the proportion difference. The default value of the NULLPROPORTIONDIFF= option specifies a test of no effect, and the default value of the GROUPWEIGHTS= option specifies a balanced design.

```sas
proc power;
  twosamplefreq test=pchi
    proportiondiff = 0.15
    refproportion = 0.4
    ntotal = 100
    power = .;
run;
```
**Fisher's Exact Conditional Test for Two Proportions**

Default values for the SIDES= and ALPHA= options specify a 2-sided test with a significance level of 0.05.

```plaintext
proc power;
   twosamplefreq test=fisher
       groupproportions = (.35 .15)
       npergroup = 50
       power = .;
run;
```

**Likelihood Ratio Chi-square Test for Two Proportions**

Default values for the SIDES= and ALPHA= options specify a 2-sided test with a significance level of 0.05.

```plaintext
proc power;
   twosamplefreq test=lrchi
       oddsratio = 2
       refproportion = 0.4
       npergroup = .
       power = 0.9;
run;
```

---

**TWOSAMPLEMEANS Statement**

```
TWOSAMPLEMEANS < options > ;
```

The TWOSAMPLEMEANS statement performs power and sample size analyses for pooled and unpooled t tests, equivalence tests, and confidence interval precision involving two independent samples.

**Summary of Options**

Table 57.18 summarizes categories of options available in the TWOSAMPLEMEANS statement.

**Table 57.18. Summary of Options in the TWOSAMPLEMEANS Statement**

**Dictionary of Options**

**ALPHA=number-list**
specifies the level of significance of the statistical test or requests a solution for alpha with a missing value (ALPHA=.). The default is 0.05, corresponding to the usual 0.05 \times 100\% = 5\% level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**CI**

**CI=DIFF**
specifies an analysis of precision of the confidence interval for the mean difference, assuming equal variances. Instead of power, the relevant probability for this analysis is the probability that the interval half-width is at most the value specified by the HALFWIDTH= option. If neither the TEST= option nor the CI= option is used, the default is TEST=DIFF.

**CV=number-list**
specifies the coefficient of variation assumed to be common to both groups. The coefficient of variation is defined as the ratio of the standard deviation to the mean. You can use this option only with DIST=LOGNORMAL. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**DIST=LOGNORMAL**

**DIST=NORMAL**
specifies the underlying distribution assumed for the test statistic. NORMAL corresponds to the normal distribution, and LOGNORMAL corresponds to the log-normal distribution. The default value (also the only acceptable value in each case) is NORMAL for TEST=DIFF, TEST=DIFF_SATT, TEST=EQUIV_DIRF, and CI=DIFF; and LOGNORMAL for TEST=RATIO and TEST=EQUIV_RATIOD.
 Chapter 57. The POWER Procedure

\textbf{GROUPMEANS=} grouped-number-list
\textbf{GMEANS=} grouped-number-list

specifies the two group means or requests a solution for one group mean given the other. Means are in the original scale. They are arithmetic if DIST=NORMAL and geometric if DIST=LOGNORMAL. This option cannot be used with the CI=DIFF analysis. When TEST=EQUIV\_DIFF, the means are interpreted as the reference mean (first) and the treatment mean (second). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

\textbf{GROUPNNS=} grouped-number-list
\textbf{GNS=} grouped-number-list

specifies the two group sample sizes or requests a solution for one group sample size given the other. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

\textbf{GROUPSTDDEVS=} grouped-number-list
\textbf{GSTDDEVS=} grouped-number-list
\textbf{GROUPSTDS=} grouped-number-list
\textbf{GSTDS=} grouped-number-list

specifies the standard deviation of each group. Unlike the STDDEV= option, the GROUPSTDDEVS= option supports different values for each group. It is valid only for the Satterthwaite \( t \) test (TEST=DIFF\_SATT DIST=NORMAL). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

\textbf{GROUPWEIGHTS=} grouped-number-list
\textbf{GWEIGHTS=} grouped-number-list

specifies the sample size allocation weights for the two groups, or requests a solution for one group weight given the other. This option controls how the total sample size is divided between the two groups. Each pair of values for the two groups represents relative allocation weights. Additionally, if the NFRACTIONAL option is not used, the total sample size is restricted to be equal to a multiple of the sum of the two group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). Values must be integers unless the NFRACTIONAL option is used. The default value is (1 1), a balanced design with a weight of 1 for each group. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

\textbf{HALFWIDTH=} number-list

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can only be used with the CI=DIFF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

\textbf{LOWER=} number-list

specifies the lower equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). Values must be greater than 0 when DIST=LOGNORMAL. This option can only be used with the TEST=EQUIV\_DIFF and TEST=EQUIV\_RATIO analyses. See the “Specifying
TWOSAMPLEMEANS Statement ♦ 3467

Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**MEANDIFF=number-list**
specifies the mean difference, defined as $\mu_2 - \mu_1$, or requests a solution for the mean difference with a missing value (MEANDIFF=.). This option can only be used with the TEST=DIFF, TEST=DIFF_SATT, and TEST=EQUIV_DIFF analyses. When TEST=EQUIV_DIFF, the mean difference is interpreted as the treatment mean minus the reference mean. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**MEANRATIO=number-list**
specifies the geometric mean ratio, defined as $\gamma_2/\gamma_1$. This option can only be used with the TEST=RATIO and TEST=EQUIV_RATIO analyses. When TEST=EQUIV_RATIO, the mean ratio is interpreted as the treatment mean divided by the reference mean. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**NFRACTIONAL**
**NFRAC**
enables fractional input and output for sample sizes. See the “Sample Size Adjustment Options” section on page 3494 for information on the ramifications of the presence (and absence) of the NFRACTIONAL option.

**NPERGROUP= number-list**
**NPERG= number-list**
specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**NTOTAL= number-list**
specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**NULLDIFF=number-list**
**NULLD=number-list**
specifies the null mean difference. The default value is 0. This option can only be used with the TEST=DIFF and TEST=DIFF_SATT analyses. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**NULLRATIO=number-list**
**NULLR=number-list**
specifies the null mean ratio. The default value is 1. This option can only be used with the TEST=RATIO analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`. 
controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- NULLDIFF
- NULLRATIO
- LOWER
- UPPER
- ALPHA
- GROUPMEANS
- MEANDIFF
- MEANRATIO
- HALFWIDTH
- STDDEV
- GROUPSTDDEVS
- CV
- GROUPWEIGHTS
- NTOTAL
- NPERGROUP
- GROUPNS
- POWER
- PROBTYPE
- PROBWIDTH

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the TWOSAMPLEMEANS statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the TWOSAMPLEMEANS statement.

POWER= number-list
specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option cannot be used with the CI=DIFF analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

PROBTYPE=keyword-list
specifies the type of probability for the PROBWIDTH= option. A value of
CONDITIONAL (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the \texttt{HALFWIDTH=} option, given that the true mean difference is captured by the confidence interval. A value of UNCONDITIONAL indicates the unconditional probability that the confidence interval half-width is at most the value specified by the \texttt{HALFWIDTH=} option. You may use the alias \texttt{GIVENV ALIDITY} for \texttt{CONDITIONAL}. The \texttt{PROBTYPE=} option can only be used with the \texttt{CI=DIFF} analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list.

**CONDITIONAL** width probability conditional on interval containing the mean

**UNCONDITIONAL** unconditional width probability

**\texttt{PROBWIDTH=}**\texttt{\textit{number-list}}
specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the \texttt{HALFWIDTH=} option. A missing value (\texttt{PROBWIDTH=}.) requests a solution for this probability. The type of probability is controlled with the \texttt{PROBTYPE=} option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can only be used with the \texttt{CI=DIFF} analysis. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the \texttt{number-list}.

**\texttt{SIDES=}**\texttt{\textit{keyword-list}}
specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the \texttt{keyword-list}. Valid keywords and their interpretation for the \texttt{TEST=} analyses are

1 \hspace{1em} 1-sided with alternative hypothesis in same direction as effect
2 \hspace{1em} 2-sided
U \hspace{1em} upper 1-sided with alternative greater than null value
L \hspace{1em} lower 1-sided with alternative less than null value

For confidence intervals, \texttt{SIDES=U} refers to an interval between the lower confidence limit and infinity, and \texttt{SIDES=L} refers to an interval between negative infinity and the upper confidence limit. For both of these cases and \texttt{SIDES=1}, the confidence interval computations are equivalent. The \texttt{SIDES=} option cannot be used with the \texttt{TEST=EQUIV-DIFF} and \texttt{TEST=EQUIV-RATIO} analyses. The default value is 2.

**\texttt{STDDEV=}**\texttt{\textit{number-list}}
specifies the standard deviation assumed to be common to both groups, or requests a solution for the common standard deviation with a missing value (\texttt{STDDEV=}.). This option can only be used with \texttt{DIST=NORMAL}. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the \texttt{number-list}.
TEST
TEST=DIFF
TEST=DIFF_SATT
TEST=EQUIVDIFF
TEST=EQUIVRATIO
TEST=RATIO

specifies the statistical analysis. TEST or TEST=DIFF (the default) specifies a pooled \(t\) test on the mean difference, assuming equal variances. TEST=DIFF_SATT specifies a Satterthwaite unpooled \(t\) test on the mean difference, assuming unequal variances. TEST=EQUIVDIFF specifies an additive equivalence test of the mean difference using a two one-sided tests (TOST) analysis (Schuirmann 1987). TEST=EQUIVRATIO specifies a multiplicative equivalence test of the mean ratio using a TOST analysis. TEST=RATIO specifies a pooled \(t\) test on the mean ratio, assuming equal coefficients of variation. If neither the TEST= option nor the CI= option is used, the default is TEST=DIFF.

UPPER=number-list

specifies the upper equivalence bound for the mean difference or mean ratio, in the original scale (whether DIST=NORMAL or DIST=LOGNORMAL). This option can only be used with the TEST=EQUIV_DIFF and TEST=EQUIV_RATIO analyses. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (using the TEST= option)
- confidence interval precision (using the CI= option)

To specify the means, choose one of the following parameterizations:

- individual group means (using the GROUPMEANS= option)
- mean difference (using the MEANDIFF= option)
- mean ratio (using the MEANRATIO= option)

To specify standard deviations in the Satterthwaite \(t\) test (TEST=DIFF_SATT), choose one of the following parameterizations:

- common standard deviation (using the STDDEV= option)
- individual group standard deviations (using the GROUPSTDDEVS= option)

To specify the sample sizes and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)
Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the TWOSAMPLEMEANS statement.

Two-sample t Test Assuming Equal Variances

You can use the NPERGROUP= option in a balanced design and express effects in terms of the mean difference. Default values for the DIST=, SIDES=, NULLDIFF=, and ALPHA= options specify a 2-sided test for no difference with a normal distribution and a significance level of 0.05.

```
proc power;
  twosamplemeans test=diff
    meandiff = 7
    stddev = 12
    npergroup = 50
    power = .;
run;
```

You can also specify an unbalanced design using the NTOTAL= and GROUPWEIGHTS= options and express effects in terms of individual group means.

```
proc power;
  twosamplemeans test=diff
    groupmeans = 8 | 15
    stddev = 4
    groupweights = (2 3)
    ntotal = .
    power = 0.9;
run;
```

Another way to specify the sample sizes is with the GROUPNS= option.

```
proc power;
  twosamplemeans test=diff
    groupmeans = 8 | 15
    stddev = 4
    groupns = (25 40)
    power = .;
run;
```
Two-sample Satterthwaite t Test Assuming Unequal Variances

Default values for the DIST=, SIDES=, NULLDIFF=, and ALPHA= options specify a 2-sided test for no difference with a normal distribution and a significance level of 0.05.

```plaintext
proc power;
  twosamplemeans test=diff_satt
      meandiff = 3
      groupstddevs = 5 | 8
      groupweights = (1 2)
      ntotal = 60
      power = .;
run;
```

Two-sample Pooled t Test of Mean Ratio with Lognormal Data

Default values for the DIST=, SIDES=, NULLRATIO=, and ALPHA= options specify a 2-sided test of mean ratio = 1 assuming a lognormal distribution and a significance level of 0.05.

```plaintext
proc power;
  twosamplemeans test=ratio
      meanratio = 7
      cv = 0.8
      groupns = 50 | 70
      power = .;
run;
```

Additive Equivalence Test for Mean Difference with Normal Data

A default value of GROUPWEIGHTS=(1 1) specifies a balanced design. Default values for the DIST= and ALPHA= options specify a significance level of 0.05 and an assumption of normally distributed data.

```plaintext
proc power;
  twosamplemeans test=equiv_diff
     lower = 2
     upper = 5
     meandiff = 4
     stddev = 8
     ntotal = .
     power = 0.9;
run;
```

Multiplicative Equivalence Test for Mean Ratio with Lognormal Data

Default values for the DIST= and ALPHA= options specify a significance level of 0.05 and an assumption of lognormally distributed data.
TWOSAMPLESURVIVAL Statement

TWOSAMPLESURVIVAL < options > ;

The TWOSAMPLESURVIVAL statement performs power and sample size analyses for comparing two survival curves. The log-rank, Gehan, and Tarone-Ware rank tests are supported.

Summary of Options

Table 57.20 summarizes categories of options available in the TWOSAMPLESURVIVAL statement.

Dictionary of Options

**ACCRUALTIME=number-list**

**ACCTIME=number-list**

**ACCRUALT=number-list**

**ACCT=number-list**

specifies the accrual time. Accrual is assumed to occur uniformly from time 0 to the time specified by the ACCRUALTIME= option. If the GROUPSURVIVAL= or REFSURVIVAL= options are used, then the value of the total time (the sum of accrual and follow-up times) must be less than or equal to the largest time in each multipoint (piecewise linear) survival curve. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.
**ALPHA= number-list**

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual $0.05 \times 100\% = 5\%$ level of significance. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`.

**CURVE("label")=points**

defines a survival curve.

For the CURVE= option,

- `label` identifies the curve in the output and with the GROUPLOSS=, GROUPSURVIVAL=, and REFSURVIVAL= options.
- `points` specifies one or more (time, survival) pairs on the curve, where the survival value denotes the probability of surviving until at least the specified time.

A single-point curve is interpreted as exponential, and a multipoint curve is interpreted as piecewise linear. Points can be expressed in either of two forms:

- a series of time:survival pairs separated by spaces. For example,
  
  \[ 1:0.9 \ 2:0.7 \ 3:0.6 \]

- a DOLIST of times enclosed in parentheses, followed by a colon (:), followed by a DOLIST of survival values enclosed in parentheses. For example,
  
  \[(1 \ to \ 3 \ by \ 1):(0.9 \ 0.7 \ 0.6)\]

  The DOLIST format is the same as in the DATA step language.

Points can also be expressed as combinations of the two forms, for example,

\[ 1:0.9 \ 2:0.8 \ (3 \ to \ 6 \ by \ 1):(0.7 \ 0.65 \ 0.6 \ 0.55)\]

The points have the following restrictions:

- the time values must be nonnegative and strictly increasing
- the survival values must be strictly decreasing
- the survival value at a time of 0 must be equal to 1
- if there is only one point, then the time must be greater than 0, and the survival value cannot be 0 or 1
FOLLOWUPTIME=number-list
FUTIME=number-list
FOLLOWUPT=number-list
FUT=number-list
specifies the follow-up time, the amount of time in the study past the accrual time. If the GROUPSURVIVAL= or REFSURVIVAL= options are used, then the value of the total time (the sum of accrual and follow-up times) must be less than or equal to the largest time in each multipoint (piecewise linear) survival curve. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

GROUPLOSS= grouped-name-list
GLOSS= grouped-name-list
specifies the exponential loss survival curve for each group, using labels specified with the CURVE= option. Loss is assumed to follow an exponential curve, indicating the expected rate of loss to follow-up over time. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-name-list.

GROUPLOSSEXPHAZARDS= grouped-number-list
GLOSSEXPHAZARDS= grouped-number-list
GROUPLOSSEXPHS= grouped-number-list
GLOSSEXPHS= grouped-number-list
specifies the exponential hazards of the loss in each group. Loss is assumed to follow an exponential curve, indicating the expected rate of loss to follow-up over time. If none of the GROUPLOSSEXPHAZARDS=, GROUPLOSS=, and GROUPMEDLOSSTIMES= options are used, the default of GROUPLOSSEXPHAZARDS=(0 0) indicates no loss to follow-up. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

GROUPMEDLOSSTIMES= grouped-number-list
GMEDLOSSTIMES= grouped-number-list
GROUPMEDLOSSTS= grouped-number-list
GMEDLOSSTS= grouped-number-list
specifies the median times of the loss in each group. Loss is assumed to follow an exponential curve, indicating the expected rate of loss to follow-up over time. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.

GROUPMEDSURVTIMES= grouped-number-list
GMEDSURVTIMES= grouped-number-list
GROUPMEDSURVTS= grouped-number-list
GMEDSURVTS= grouped-number-list
specifies the median survival times in each group. When the GROUPMEDSURVTIMES= option is used, the survival curve in each group is assumed to be exponential. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the grouped-number-list.
GROUPNS= grouped-number-list
GNS= grouped-number-list
  specifies the two group sample sizes or requests a solution for one group sample size
given the other. See the “Specifying Value Lists in Analysis Statements” section on
page 3490 for information on specifying the grouped-number-list.

GROUPSURVEXPHAZARDS= grouped-number-list
GSURVEXPHAZARDS= grouped-number-list
GROUPSURVEXPXS= grouped-number-list
GEXPHS= grouped-number-list
  specifies exponential hazard rates of the survival curve for each group. See the
  “Specifying Value Lists in Analysis Statements” section on page 3490 for information
  on specifying the grouped-number-list.

GROUPSURVIVAL= grouped-name-list
GSURVIVAL= grouped-name-list
GROUPSURV= grouped-name-list
GSURV= grouped-name-list
  specifies the survival curve for each group, using labels specified with the CURVE= 
option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 
for information on specifying the grouped-name-list.

GROUPWEIGHTS= grouped-number-list
GWEIGHTS= grouped-number-list
  specifies the sample size allocation weights for the two groups, or requests a solution 
for one group weight given the other. This option controls how the total sample size
is divided between the two groups. Each pair of values for the two groups represents
relative allocation weights. Additionally, if the NFRACTIONAL option is not used,
the total sample size is restricted to be equal to a multiple of the sum of the two group
weights (so that the resulting design has an integer sample size for each group while
adhering exactly to the group allocation weights). Values must be integers unless the
NFRACTIONAL option is used. The default value is (1 1), a balanced design with a
weight of 1 for each group. See the “Specifying Value Lists in Analysis Statements”
section on page 3490 for information on specifying the grouped-number-list.

HAZARDRATIO= number-list
HR= number-list
  specifies the hazard ratio of the second group’s survival curve to the first group’s
survival curve. See the “Specifying Value Lists in Analysis Statements” section on
page 3490 for information on specifying the number-list.

NFRATIONAL
NFRAC
  enables fractional input and output for sample sizes. See the “Sample Size 
Adjustment Options” section on page 3494 for information on the ramifications of
the presence (and absence) of the NFRATIONAL option.
**NPERGROUP= number-list**

**NPERG= number-list**

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (NPERGROUP=.). Use of this option implicitly specifies a balanced design. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**NSUBINTERVAL= number-list**

**NSUBINTERVALS= number-list**

**NSUB= number-list**

**NSUBS= number-list**

specifies the number of subintervals per unit time to use in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. The default value is 12. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**NTOTAL= number-list**

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the *number-list*.

**OUTPUTORDER=INTERNAL**

**OUTPUTORDER=REVERSE**

**OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) produces output sorted respectively by

- SIDES
- ACCRUALTIME
- FOLLOWUPTIME
- TOTALTIME
- NSUBINTERVAL
- ALPHA
- REFSURVIVAL
- GROUPSURVIVAL
- REFSURVEXPHAZARD
- HAZARDRATIO
- GROUPSURVEXPHAZARDS
- GROUPMEDSURVTIMES
- GROUPLOSSEXPHAZARDS
- GROUPLOSS
- GROUPMEDLOSSTIMES
- GROUPWEIGHTS
The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order that their corresponding options are specified in the TWOSAMPLESURVIVAL statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order that their corresponding options are specified in the TWOSAMPLESURVIVAL statement.

**POWER= number-list**
specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**REFSURVEXPHAZARD= number-list**
**REFSURVEXPH= number-list**
specifies the exponential hazard rate of the survival curve for the first (reference) group. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

**REFSURVIVAL= name-list**
**REFSURV= name-list**
specifies the survival curve for the first (reference) group, using labels specified with the CURVE= option. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the name-list.

**SIDES=keyword-list**
specifies the number of sides (or tails) and direction of the statistical test or confidence interval. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the keyword-list. Valid keywords and their interpretation are

1 1-sided with alternative hypothesis in same direction as effect
2 2-sided
U upper 1-sided with the alternative hypothesis favoring better survival in the second group
L lower 1-sided with the alternative hypothesis favoring better survival in the first (reference) group

The default value is 2.
TEST=GEHAN
TEST=LOGRANK
TEST=TARONEWARE

specifies the statistical analysis. TEST=GEHAN specifies the Gehan rank test. TEST=LOGRANK (the default) specifies the log-rank test. TEST=TARONEWARE specifies the Tarone-ware rank test.

TOTALTIME=number-list
TOTALT=number-list

specifies the total time, which is equal to the sum of accrual and follow-up times. If the GROUPSURVIVAL= or REFSURVIVAL= options are used, then the value of the total time must be less than or equal to the largest time in each multipoint (piecewise linear) survival curve. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

Restrictions on Option Combinations

To specify the survival curves, choose one of the following parameterizations:

- arbitrary piecewise linear or exponential curves (using the CURVE= and GROUPSURVIVAL= options)
- curves with proportional hazards (using the CURVE=, REFSURVIVAL=, and HAZARDRATIO= options)
- exponential curves, using one of the following parameterizations:
  - median survival times (using the GROUPMEDSURVTIME= option)
  - the hazard ratio and the hazard of the reference curve (using the HAZARDRATIO= and REFSURVEXPHAZARD= options)
  - the individual hazards (using the GROUPSURVEXPHAZARDS= option)

To specify the study time, use any two of the following three options:

- accrual time (using the ACCRUALTIME= option)
- follow-up time (using the FOLLOWUPTIME= option)
- total time, the sum of accrual and follow-up times (using the TOTALTIME= option)

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (using the NPERGROUP= option)
- total sample size and allocation weights (using the NTOTAL= and GROUPWEIGHTS= options)
- individual group sample sizes (using the GROUPNS= option)

To specify the exponential loss curves, choose one of the following parameterizations:
• a point on the loss curve of each group (using the CURVE= and GROUPLOSS= options)
• median loss times (using the GROUPMEDLOSSTIMES= option)
• the individual loss hazards (using the GROUPLOSSEXPHAZARDS= option)

**Option Groups for Common Analyses**

This section summarizes the syntax for the common analyses supported in the TWOSAMPLESURVIVAL statement.

**Log-Rank Test for Two Survival Curves**

You can use the NPERGROUP= option in a balanced design and specify piecewise linear or exponential survival curves using the CURVE= and GROUPSURVIVAL= options. Default values for the SIDES=, ALPHA=, NSUBINTERVAL=, and GROUPLOSSEXPHAZARDS= options specify a 2-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```sas
proc power;
  twosamplesurvival test=logrank
    curve("Control") = (1 2 3):(0.8 0.7 0.6)
    curve("Treatment") = (5):(.6)
    groupsurvival = "Control" | "Treatment"
    accrualtime = 2
    followuptime = 1
    npergroup = 50
    power = .;
run;
```

In the preceding example, the “Control” curve is piecewise linear (since it has more than one point), and the “Treatment” curve is exponential (since it has only one point).

You can also specify an unbalanced design using the NTOTAL= and GROUPWEIGHTS= options and specify piecewise linear or exponential survival curves with proportional hazards using the CURVE=, REFSURVIVAL=, and HAZARDRATIO= options.

```sas
proc power;
  twosamplesurvival test=logrank
    curve("Control") = (1 2 3):(0.8 0.7 0.6)
    refsurvival = "Control"
    hazardratio = 1.5
    accrualtime = 2
    followuptime = 1
    groupweights = (1 2)
    ntotal = .
    power = 0.8;
run;
```

You can also specify sample sizes with the GROUPNS= option and specify exponential survival curves in terms of median survival times.
PROC POWER;
  TWOSAMPLESURVIVAL TEST=LOGRANK
    GROUPMEDSURVTIMES = (16 22)
    ACCRUALTIME = 6
    TOTALTIME = 18
    GROUNDS = 40 | 60
    POWER = .;
RUN;

You can also specify exponential survival curves in terms of the hazard ratio and reference hazard. The default value of the GROUPWEIGHTS= option specifies a balanced design.

PROC POWER;
  TWOSAMPLESURVIVAL TEST=LOGRANK
    HAZARDRATIO = 1.2
    REFSURVEXPHazard = 0.7
    ACCRUALTIME = 2
    TOTALTIME = 4
    NTOTAL = 100
    POWER = .;
RUN;

You can also specify exponential survival curves in terms of the individual hazards.

PROC POWER;
  TWOSAMPLESURVIVAL TEST=LOGRANK
    GROUPSURVEXPHAZARDS = 0.7 | 0.84
    ACCRUALTIME = 2
    TOTALTIME = 4
    NTOTAL = .
    POWER = 0.9;
RUN;

Gehan Rank Test for Two Survival Curves

Default values for the SIDES=, ALPHA=, NSUBINTERVAL=, and GROUPLOSEXPHAZARDS= options specify a 2-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

PROC POWER;
  TWOSAMPLESURVIVAL TEST=Gehan
    GROUPMEDSURVTIMES = 5 | 7
    ACCRUALTIME = 3
    TOTALTIME = 6
    NPERGROUP = .
    POWER = 0.8;
RUN;
Tarone-Ware Rank Test for Two Survival Curves

Default values for the SIDES=, ALPHA=, NSUBINTERVAL=, and GROUPLOSESEXPHAZARDS= options specify a 2-sided test with a significance level of 0.05, an assumption of no loss to follow-up, and the use of 12 subintervals per unit time in computations.

```sas
proc power;
   twosamplesurvival test=taroneware
      groupmedsurvtimes = 5 | 7
      accrualtime = 3
      totaltime = 6
      npergroup = 100
      power = .;
run;
```

PLOT Statement

```
PLOT < plot-options > < l graph-options > ;
```

The PLOT statement produces a graph or set of graphs for the sample size analysis defined by the previous analysis statement. The plot-options define the plot characteristics, and the graph-options are SAS/GRAPH-style options.

Options

You can specify the following plot-options in the PLOT statement.

- **INTERPOL=JOIN**
- **INTERPOL=NONE**
  specifies the type of curve to draw through the computed points. The INTERPOL=JOIN option connects computed points by straight lines. The INTERPOL=NONE option leaves computed points unconnected.

- **KEY= BYCURVE < ( bycurve-options ) >**
- **KEY= BYFEATURE < ( byfeature-options ) >**
- **KEY= ONCURVES**
  specifies the style of key (or “legend”) for the plot. The default is KEY=BYFEATURE, which specifies a key with a column of entries for each plot feature (line style, color, and/or symbol). Each entry shows the mapping between a value of the feature and the value(s) of the analysis parameter(s) linked to that feature. The KEY=BYCURVE option specifies a key with each row identifying a distinct curve in the plot. The KEY=ONCURVES option places a curve-specific label adjacent to each curve.

You can specify the following byfeature-options in parentheses after the KEY=BYCURVE option.
NUMBERS=OFF
NUMBERS=ON specifies how the key should identify curves. If NUMBERS=OFF, then the key includes symbol, color, and line style samples to identify the curves. If NUMBERS=ON, then the key includes numbers matching numeric labels placed adjacent to the curves. The default is NUMBERS=ON.

POS=BOTTOM
POS=INSET specifies the position of the key. The POS=BOTTOM option places the key below the x-axis. The POS=INSET option places the key inside the plotting region and attempts to choose the least crowded corner. The default is POS=BOTTOM.

You can specify the following by/feature-options in parentheses after the KEY=BYFEATURE option.

POS=BOTTOM
POS=INSET specifies the position of the key. The POS=BOTTOM option places the key below the x-axis. The POS=INSET option places the key inside the plotting region and attempts to choose the least crowded corner. The default is POS=BOTTOM.

MARKERS=ANALYSIS
MARKERS=COMPUTED
MARKERS=NICE
MARKERS=NONE specifies the locations for plotting symbols.

The MARKERS=ANALYSIS option places plotting symbols at locations corresponding to the values of the relevant input parameter from the analysis statement preceding the PLOT statement.

The MARKERS=COMPUTED option (the default) places plotting symbols at the locations of actual computed points from the sample size analysis.

The MARKERS=NICE option places plotting symbols at tick mark locations (corresponding to the argument axis).

The MARKERS=NONE option disables plotting symbols.

MAX=number specifies the maximum of the range of values for the parameter associated with the “argument” axis (the axis that is not representing the parameter being solved for). The default is the maximum value occurring for this parameter in the analysis statement preceding the PLOT statement.

MIN=number specifies the minimum of the range of values for the parameter associated with the “argument” axis (the axis that is not representing the parameter being solved for). The
default is the minimum value occurring for this parameter in the analysis statement preceding the PLOT statement.

NPOINTS=number
NPTS=number
specifies the number of values for the parameter associated with the “argument” axis (the axis that is not representing the parameter being solved for). You cannot use the NPOINTS= and STEP= options simultaneously. The default value for typical situations is 20.

STEP=number
specifies the increment between values of the parameter associated with the “argument” axis (the axis that is not representing the parameter being solved for). You cannot use the STEP= and NPOINTS= options simultaneously. By default, the NPOINTS= option is used instead of the STEP= option.

VARY ( feature < BY parameter-list > ... feature < BY parameter-list > )
specifies how plot features should be linked to varying analysis parameters. Available plot features are COLOR, LINESTYLE, PANEL, and SYMBOL. A “panel” refers to a separate plot with a heading identifying the subset of values represented in the plot.

The parameter-list is a list of one or more names separated by spaces. Each name must match the name of an analysis option used in the analysis statement preceding the PLOT statement. Also, the name must be the primary name for the analysis option, that is, the one listed first in the syntax description.

If you omit the < BY parameter-list > portion for a feature, then one or more multi-valued parameters from the analysis will be automatically selected for you.

X=EFFECT
X=N
X=POWER
specifies a plot with the requested type of parameter on the x-axis and the parameter being solved for on the y-axis. When X=EFFECT, the parameter assigned to the x-axis is the one most representative of “effect size.” When X=N, the parameter assigned to the x-axis is the sample size. When X=POWER, the parameter assigned to the x-axis is the one most representative of “power” (either power itself or a similar probability, such as Prob(Width) for confidence interval analyses). You cannot use the X= and Y= options simultaneously. The default is X=POWER, unless the result parameter is power or Prob(Width), in which case the default is X=N.

You can only use the X=N option when a scalar sample size parameter is used as input in the analysis. For example, X=N can be used with total sample size or sample size per group, or with two group sample sizes when one is being solved for.

Table 57.22 summarizes the parameters representing effect size in different analyses.

</tbody>
</table>

**XOPTS=(x-options)**

specifies plot characteristics pertaining to the x-axis.

You can specify the following `x-options` in parentheses.

**CROSSREF=NO**

**CROSSREF=YES** specifies whether the reference lines defined by the `REF=x-option` should be crossed with a reference line on the y-axis that indicates the solution point on the curve.

**REF=number-list** specifies locations for reference lines extending from the x-axis across the entire plotting region. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the `number-list`. 
Y=EFFECT
Y=N
Y=POWER
specifies a plot with the requested type of parameter on the y-axis and the parameter being solved for on the x-axis. When Y=EFFECT, the parameter assigned to the y-axis is the one most representative of “effect size.” When Y=N, the parameter assigned to the y-axis is the sample size. When Y=POWER, the parameter assigned to the y-axis is the one most representative of “power” (either power itself or a similar probability, such as Prob(Width) for confidence interval analyses). You cannot use the Y= and X= options simultaneously. By default, the X= option is used instead of the Y= option.

YOPTS= ( y-options )
specifies plot characteristics pertaining to the y-axis.

You can specify the following y-options in parentheses.

CROSSREF=NO
CROSSREF=YES 
sp-em}cifies whether the reference lines defined by the REF= y-option should be crossed with a reference line on the x-axis that indicates the solution point on the curve.

REF=number-list 
specifies locations for reference lines extending from the y-axis across the entire plotting region. See the “Specifying Value Lists in Analysis Statements” section on page 3490 for information on specifying the number-list.

You can specify the following graph-options in the PLOT statement after a slash (/).

DESCRIPTION='string '
specifies a descriptive string of up to 40 characters that appears in the “Description” field of the graphics catalog. The description does not appear on the plots. By default, PROC POWER assigns a description either of the form “Y versus X” (for a single-panel plot) or of the form “Y versus X (S),” where Y is the parameter on the y-axis, X is the parameter on the x-axis, and S is a description of the subset represented on the current panel of a multipanel plot.

NAME='string '
specifies a name of up to eight characters for the catalog entry for the plot. The default name is PLOTn, where n is the number of the plot statement within the current invocation of PROC POWER. If the name duplicates the name of an existing entry, SAS/GRAPH software adds a number to the duplicate name to create a unique entry; for example, PLOT11 and PLOT12 for the second and third panels of a multipanel plot generated in the first PLOT statement in an invocation of PROC POWER.
Overview of Power Concepts

In statistical hypothesis testing, you typically express the belief that some effect exists in a population by specifying an alternative hypothesis $H_1$. You state a null hypothesis $H_0$ as the assertion that the effect does not exist and attempt to gather evidence to reject $H_0$ in favor of $H_1$. Evidence is gathered in the form of sample data, and a statistical test is used to assess $H_0$. If $H_0$ is rejected but there really is no effect, this is called a Type 1 error. The probability of a Type 1 error is usually designated “alpha” or $\alpha$, and statistical tests are designed to ensure that $\alpha$ is suitably small (for example, less than 0.05).

If there really is an effect in the population but $H_0$ is not rejected in the statistical test, then a Type 2 error has been made. The probability of a Type 2 error is usually designated “beta” or $\beta$. The probability $1 - \beta$ of avoiding a Type 2 error, that is, correctly rejecting $H_0$ and achieving statistical significance, is called the power. (Note: Another more general definition of power is the probability of rejecting $H_0$ for any given set of circumstances, even those corresponding to $H_0$ being true. The POWER procedure uses this more general definition.)

An important goal in study planning is to ensure an acceptably high level of power. Sample size plays a prominent role in power computations because the focus is often on determining a sufficient sample size to achieve a certain power, or assessing the power for a range of different sample sizes.

Some of the analyses in the POWER procedure focus on precision rather than power. An analysis of confidence interval precision is analogous to a traditional power analysis, with “CI Half-Width” taking the place of effect size and “Prob(Width)” taking the place of power. The CI Half-Width is the margin of error associated with the confidence interval, the distance between the point estimate and an endpoint. The $Prob(Width)$ is the probability of obtaining a confidence interval with at most a target half-width.

Summary of Analyses

Table 57.23 gives a summary of the analyses supported in the POWER procedure. The name of the analysis statement reflects the type of data and design. The TEST=, CI=, and DIST= options specify the focus of the statistical hypothesis (in other words, the criterion on which the research question is based) and the test statistic to be used in data analysis.

### Specifying Value Lists in Analysis Statements

To specify one or more scenarios for an analysis parameter (or set of parameters), you provide a list of values for the statement option that corresponds to the parameter(s). To identify the parameter you wish to solve for, you place missing values in the appropriate list.

There are five basic types of such lists: **keyword-lists**, **number-lists**, **grouped-number-lists**, **name-lists**, and **grouped-name-lists**. Some parameters, such as the direction of a test, have values represented by one or more keywords in a **keyword-list**. Scenarios for scalar-valued parameters, such as power, are represented by a **number-list**. Scenarios for groups of scalar-valued parameters, such as group sample sizes in a multigroup design, are represented by a **grouped-number-list**. Scenarios for named parameters, such as reference survival curves, are represented by a **name-list**. Scenarios for groups of named parameters, such as group survival curves, are represented by a **grouped-name-list**.

The following subsections explain these five basic types of lists.

#### Keyword-lists

A **keyword-list** is a list of one or more keywords separated by spaces. For example, you can specify both 2-sided and upper-tailed versions of a one-sample \( t \) test:

\[
\text{SIDES} = 2 \ U
\]
**Number-lists**

A *number-list* can be one of two things: a series of one or more numbers expressed in the form of one or more DOLISTs, or a missing value indicator (\( . \)).

The DOLIST format is the same as in the DATA step language. For example, for the one-sample \( t \) test you can specify four scenarios (30, 50, 70, and 100) for a total sample size in any of the following ways:

\[
\begin{align*}
\text{N\textsc{total}} &= 30 \text{ to } 70 \text{ by } 20 \text{ 100} \\
\text{N\textsc{total}} &= 30 \text{ 50 70 100}
\end{align*}
\]

A missing value identifies a parameter as the result parameter; it is valid only with options representing parameters you can solve for in a given analysis. For example, you can request a solution for N\textsc{total}:

\[ \text{N\textsc{total}} = . \]

**Grouped-number-lists**

A *grouped-number-list* specifies multiple scenarios for numeric values in two or more groups, possibly including missing value indicators to solve for a specific group. The list can assume one of two general forms, a “crossed” version and a “matched” version.

**Crossed Grouped-number-lists**

The crossed version of a grouped number list consists of a series of *number-lists* (see the “Number-lists” section on page 3491), one representing each group, each separated by a vertical bar (\(|\)). The values for each group represent multiple scenarios for that group, and the scenarios for each individual group are crossed to produce the set of all scenarios for the analysis option. For example, you can specify the following six scenarios for the sizes \( (n_1, n_2) \) of two groups:

\[
\begin{align*}
(20, 30) & (20, 40) (20, 50) \\
(25, 30) & (25, 40) (25, 50)
\end{align*}
\]

as follows:

\[ \text{GROUP\textsc{NS}} = 20 \text{ 25} \text{ } | \text{ } 30 \text{ 40 50} \]

If the analysis can solve for a value in one group given the other groups, then one of the *number-lists* in a crossed grouped-number-list can be a missing value indicator (\( . \)). For example, in a two-sample \( t \) test you can posit three scenarios for the group 2 sample size while solving for the group 1 sample size:

\[ \text{GROUP\textsc{NS}} = . \text{ } | \text{ } 30 \text{ 40 50} \]

Some analyses can involve more than two groups. For example, you can specify \( 2 \times 3 \times 1 = 6 \) scenarios for the means of three groups in a one-way ANOVA as follows:

\[ \text{GROUP\textsc{MEANS}} = 10 \text{ 12 } | \text{ } 10 \text{ to } 20 \text{ by } 5 \text{ } | \text{ } 24 \]
Matched Grouped-number-lists

The matched version of a grouped number list consists of a series of numeric lists each enclosed in parentheses. Each list consists of a value for each group and represents a single scenario for the analysis option. Multiple scenarios for the analysis option are represented by multiple lists. For example, you can express the crossed grouped-number-list

\[
\text{GROUPNS} = 20 \ 25 \ | \ 30 \ 40 \ 50
\]

alternatively in a matched format:

\[
\text{GROUPNS} = (20 \ 30) \ (20 \ 40) \ (20 \ 50) \ (25 \ 30) \ (25 \ 40) \ (25 \ 50)
\]

The matched version is particularly useful when you wish to include only a subset of all combinations of individual group values. For example, you may want to pair 20 only with 50, and 25 only with 30 and 40:

\[
\text{GROUPNS} = (20 \ 50) \ (25 \ 30) \ (25 \ 40)
\]

If the analysis can solve for a value in one group given the other groups, then you can replace the value for that group with a missing value indicator (.). If used, the missing value indicator must occur in the same group in every scenario. For example, you can solve for the group 1 sample size (as in the “Crossed Grouped-number-lists” section on page 3491) using a matched format:

\[
\text{GROUPNS} = (. \ 30) \ (. \ 40) \ (. \ 50)
\]

Some analyses can involve more than two groups. For example, you can specify two scenarios for the means of three groups in a one-way ANOVA:

\[
\text{GROUPMEANS} = (15 \ 24 \ 32) \ (12 \ 25 \ 36)
\]

Name-lists

A name-list is a list of one or more names in single or double quotes separated by spaces. For example, you can specify two scenarios for the reference survival curve in a log-rank test:

\[
\text{REFSURVIVAL} = "Curve A" \ "Curve B"
\]

Grouped-name-lists

A grouped-name-list specifies multiple scenarios for names in two or more groups. The list can assume one of two general forms, a “crossed” version and a “matched” version.
Crossed Grouped-name-lists

The crossed version of a grouped name list consists of a series of name-lists (see the “Name-lists” section on page 3492), one representing each group, each separated by a vertical bar (|). The values for each group represent multiple scenarios for that group, and the scenarios for each individual group are crossed to produce the set of all scenarios for the analysis option. For example, you can specify the following six scenarios for the survival curves \((c_1, c_2)\) of two groups:

\[
\begin{align*}
(\text{“Curve A”}, \text{“Curve C”}) & (\text{“Curve A”}, \text{“Curve D”}) (\text{“Curve A”}, \text{“Curve E”}) \\
(\text{“Curve B”}, \text{“Curve C”}) & (\text{“Curve B”}, \text{“Curve D”}) (\text{“Curve B”}, \text{“Curve E”})
\end{align*}
\]

as follows:

\[
\text{GROUPSURVIVAL} = \text{“Curve A”} \hspace{1mm} \text{“Curve B”} \hspace{1mm} | \hspace{1mm} \text{“Curve C”} \hspace{1mm} \text{“Curve D”} \hspace{1mm} \text{“Curve E”}
\]

Matched Grouped-name-lists

The matched version of a grouped name list consists of a series of name lists each enclosed in parentheses. Each list consists of a name for each group and represents a single scenario for the analysis option. Multiple scenarios for the analysis option are represented by multiple lists. For example, you can express the crossed grouped-name-list:

\[
\text{GROUPSURVIVAL} = \text{“Curve A”} \hspace{1mm} \text{“Curve B”} \hspace{1mm} | \hspace{1mm} \text{“Curve C”} \hspace{1mm} \text{“Curve D”} \hspace{1mm} \text{“Curve E”}
\]

alternatively in a matched format:

\[
\text{GROUPSURVIVAL} = (\text{“Curve A”} \hspace{1mm} \text{“Curve C”})
(\text{“Curve A”} \hspace{1mm} \text{“Curve D”})
(\text{“Curve A”} \hspace{1mm} \text{“Curve E”})
(\text{“Curve B”} \hspace{1mm} \text{“Curve C”})
(\text{“Curve B”} \hspace{1mm} \text{“Curve D”})
(\text{“Curve B”} \hspace{1mm} \text{“Curve E”})
\]

The matched version is particularly useful when you wish to include only a subset of all combinations of individual group values. For example, you may want to pair “Curve A” only with “Curve C”, and “Curve B” only with “Curve D” and “Curve E”:

\[
\text{GROUPSURVIVAL} = (\text{“Curve A”} \hspace{1mm} \text{“Curve C”})
(\text{“Curve B”} \hspace{1mm} \text{“Curve D”})
(\text{“Curve B”} \hspace{1mm} \text{“Curve E”})
\]
Sample Size Adjustment Options

By default, PROC POWER rounds sample sizes conservatively (down in the input, up in the output) so that all total sizes (and individual group sample sizes, if a multigroup design) are integers. This is generally considered conservative because it selects the closest realistic design providing at most the power of the (possibly fractional) input or mathematically optimized design. In addition, in a multigroup design, all group sizes are adjusted to be multiples of the corresponding group weights. For example, if GROUPWEIGHTS = (2 6), then all group 1 sample sizes become multiples of 2, and all group 2 sample sizes become multiples of 6 (and all total sample sizes become multiples of 8).

With the NFRACTIONAL option, sample size input is not rounded, and sample size output (whether total or group-wise) are reported in two versions, a raw “fractional” version and a “ceiling” version rounded up to the nearest integer.

Whenever an input sample size is adjusted, both the original (“nominal”) and adjusted (“actual”) sample sizes are reported. Whenever computed output sample sizes are adjusted, both the original input (“nominal”) power and the achieved (“actual”) power at the adjusted sample size are reported.

Error and Information Output

The Error column in the main output table explains reasons for missing results and flags numerical results that are bounds rather than exact answers. For example, consider the sample size analysis implemented by the following statements:

```plaintext
proc power;
  twosamplefreq test=pchi
    oddsratio= 1.0001
    refproportion=.4
    nulloddsratio=1
    power=.9
    ntotal=.;
run;
```

</tr>
</thead>
<tbody>
<tr>
<td>0.206</td>
<td>2.15E+09</td>
<td>Solution is a lower bound</td>
</tr>
</tbody>
</table>

Figure 57.6. Error Column

The output in Figure 57.6 reveals that the sample size to achieve a power of 0.9 could not be computed, but that the sample size 2.15E+09 achieves a power of 0.206.

The Information column provides further details about Error entries, warnings about any boundary conditions detected, and notes about any adjustments to input. Note that the Information column is hidden by default in the main output. You can view it by using the ODS OUTPUT statement to save the output as a data set and the PRINT procedure. For example, the following SAS statements print both the Error and Info columns for a power computation in a two-sample $t$ test.

```sas
proc power;
   twosamplemeans
      meandiff= 0 7
      stddev=2
      ntotal=2 5
      power=.;
   ods output output=Power;
   proc print noobs data=Power;
      var MeanDiff NominalNTotal NTotal Power Error Info;
   run;
```

The output is shown in Figure 57.7.
Table 57.7. Error and Information Columns

The mean difference of 0 specified with the MEANDIFF= option leads to a “No effect” message to appear in the Info column. The sample size of 2 specified with the NTOTAL= option leads to an “Invalid input” message in the Error column and an “NTotal too small” message in the Info column. The sample size of 5 leads to an “Input N adjusted” message in the Info column because it is rounded down to 4 to produce integer group sizes of 2 per group.

Displayed Output

If you use the PLOTONLY option in the PROC POWER statement, the procedure only displays graphical output. Otherwise, the displayed output of the POWER procedure includes the following:

- the “Fixed Scenario Elements” table, which shows all applicable single-valued analysis parameters, in the following order: distribution, method, parameters input explicitly, and parameters supplied with defaults
- an output table showing the following when applicable (in order): the index of the scenario, all multivalued input, ancillary results, the primary computed result, and error descriptions
- plots (if requested)

For each input parameter, the order of the input values is preserved in the output.

Ancillary results include the following:

- Actual Power, the achieved power, if it differs from the input (Nominal) power value
- Actual Prob(Width), the achieved precision probability, if it differs from the input (Nominal) probability value
- Actual Alpha, the achieved significance level, if it differs from the input (Nominal) alpha value
- fractional sample size, if the NFRACTIONAL option is used in the analysis statement

If sample size is the result parameter and the NFRACTIONAL option is used in the analysis statement, then both “Fractional” and “Ceiling” sample size results are
displayed. Fractional sample sizes correspond to the “Nominal” values of power or precision probability. Ceiling sample sizes are simply the fractional sample sizes rounded up to the nearest integer; they correspond to “Actual” values of power or precision probability.

ODS Table Names

PROC POWER assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 57.24. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

Table 57.24. ODS Tables Produced in PROC POWER

<table>
<thead>

<td>default</td>
</tr>
<tr>
<td>PlotContent</td>
<td>data contained in plots, including analysis parameters and indices identifying plot features. (Note: this table is saved as a data set and not displayed in PROC POWER output.)</td>
<td>PLOT</td>
</tr>
</tbody>
</table>

*Depends on input.

The ODS path names are created as follows:

- Power.<analysis statement name><n>.FixedElements
- Power.<analysis statement name><n>.Output
- Power.<analysis statement name><n>.PlotContent
- Power.<analysis statement name><n>.Plot<m>

where

- The Plot<m> objects are the graphs.
- The <n> indexing the analysis statement name is only used if there is more than one instance.
- The <n> indexing the plots increases with every panel in every plot statement, resetting to 1 only at new analysis statements.
Computational Resources

Memory

In the TWOSAMPLESURVIVAL statement, the amount of required memory is roughly proportional to the product of the number of subintervals (specified by the NSUBINTERVAL= option) and the total time of the study (specified by the ACCRUALTIME=, FOLLOWUPTIME=, and TOTALTIME= options).

CPU Time

In the Satterthwaite t test analysis (TWOSAMPLEMEANS TEST=DIFF–SATT), the required CPU time grows as the mean difference decreases relative to the standard deviations. In the PAIREDFREQ statement, the required CPU time for the exact power computation (METHOD=EXACT) grows with the sample size.

Computational Methods and Formulas

This section describes the approaches used in PROC POWER to compute power for each analysis. The first subsection defines some common notation. The following subsections describe the various power analyses, including discussions of the data, statistical test, and power formula for each analysis. Unless otherwise indicated, computed values for parameters besides power (for example, sample size) are obtained by solving power formulas for the desired parameters.

Common Notation

Table 57.25 displays notation for some of the more common parameters across analyses. The Associated Syntax column shows examples of relevant analysis statement options, where applicable.

</table>

A “lower 1-sided” test is associated with SIDES=L (or SIDES=1 with the effect smaller than the null value), and an “upper 1-sided” test is associated with SIDES=U (or SIDES=1 with the effect larger than the null value).

Owen (1965) defines a function, known as Owen’s $Q$, that is convenient for representing terms in power formulas for confidence intervals and equivalence tests:

$$Q_{\nu}(t, \delta; a, b) = \frac{\sqrt{2\pi}}{\Gamma(\nu)^{2\nu+2}} \int_{a}^{b} \Phi \left( \frac{tx - \delta}{\sqrt{\nu}} \right) x^{\nu-1} \phi(x) \, dx$$

where $\phi(\cdot)$ and $\Phi(\cdot)$ are the density and cumulative distribution function of the standard normal distribution, respectively.
Analyses in the MULTREG Statement

Type III F Test in Multiple Regression (TEST=TYPE3)

Maxwell (2000) discusses a number of different ways to represent effect sizes (and to compute exact power based on them) in multiple regression. PROC POWER supports two of these, multiple partial correlation and $R^2$ in full and reduced models.

Let $p$ denote the total number of predictors in the full model (excluding the intercept) and $Y$ the response variable. You are testing that the coefficients of $p_1 \geq 1$ predictors in a set $X_1$ are 0, controlling for all of the other predictors $X_{-1}$, which is comprised of $p - p_1 \geq 0$ variables.

The hypotheses can be expressed in two different ways. The first is in terms of $\rho_{Y,X_1|X_{-1}}$, the multiple partial correlation between the predictors in $X_1$ and the response $Y$ adjusting for the predictors in $X_{-1}$:

$$
H_0 : \quad \rho_{Y,X_1|X_{-1}}^2 = 0 \\
H_1 : \quad \rho_{Y,X_1|X_{-1}}^2 > 0
$$

The second is in terms of the multiple correlations in full ($\rho_{Y|(X_1,X_{-1})}$) and reduced ($\rho_{Y|X_{-1}}$) nested models:

$$
H_0 : \quad \rho_{Y|(X_1,X_{-1})}^2 - \rho_{Y|X_{-1}}^2 = 0 \\
H_1 : \quad \rho_{Y|(X_1,X_{-1})}^2 - \rho_{Y|X_{-1}}^2 > 0
$$

Note that the squared values of $\rho_{Y|(X_1,X_{-1})}$ and $\rho_{Y|X_{-1}}$ are the population $R^2$ values for full and reduced models.

The test statistic can be written in terms of the sample multiple partial correlation $\hat{R}_{Y,X_1|X_{-1}}^2$,

$$
F = \begin{cases} 
(N - 1 - p) \frac{\hat{R}_{Y,X_1|X_{-1}}^2}{1 - \hat{R}_{Y,X_1|X_{-1}}^2}, & \text{intercept} \\
(N - p) \frac{\hat{R}_{Y,X_1|X_{-1}}^2}{1 - \hat{R}_{Y,X_1|X_{-1}}^2}, & \text{no intercept}
\end{cases}
$$

or the sample multiple correlations in full ($\hat{R}_{Y|(X_1,X_{-1})}^2$) and reduced ($\hat{R}_{Y|X_{-1}}^2$) models,

$$
F = \begin{cases} 
(N - 1 - p) \frac{\hat{R}_{Y|(X_1,X_{-1})}^2 - \hat{R}_{Y|X_{-1}}^2}{1 - \hat{R}_{Y|(X_1,X_{-1})}^2}, & \text{intercept} \\
(N - p) \frac{\hat{R}_{Y|(X_1,X_{-1})}^2 - \hat{R}_{Y|X_{-1}}^2}{1 - \hat{R}_{Y|(X_1,X_{-1})}^2}, & \text{no intercept}
\end{cases}
$$
The test is the usual Type III $F$ test in multiple regression:

\[
\begin{align*}
\text{Reject } H_0 \text{ if } & \begin{cases} 
F \geq F_{1-\alpha}(p_1, N - 1 - p), & \text{intercept} \\
F \geq F_{1-\alpha}(p_1, N - p), & \text{no intercept}
\end{cases}
\end{align*}
\]

Although the test is invariant to whether the predictors are assumed to be random or fixed, the power is affected by this assumption. If the response and predictors are assumed to have a joint multivariate normal distribution, then the exact power is given by the following formula:

\[
\text{power} = \begin{cases} 
P \left[ \frac{N-1-p}{p_1} \left( \frac{R^2_Y((X_1,X_{-1}))}{1-R^2_Y((X_1,X_{-1}))} \right) \geq F_{1-\alpha}(p_1, N - 1 - p) \right], & \text{intercept} \\
P \left[ \frac{N-p}{p_1} \left( \frac{R^2_Y((X_1,X_{-1}))}{1-R^2_Y((X_1,X_{-1}))} \right) \geq F_{1-\alpha}(p_1, N - p) \right], & \text{no intercept}
\end{cases}
\]

The distribution of $R^2_Y((X_1,X_{-1})$ (for any $\rho^2_Y((X_1,X_{-1})$) is given in Chapter 32 of Johnson, Kotz, and Balakrishnan (1995). Sample size tables are presented in Gatsonis and Sampson (1989).

If the predictors are assumed to have fixed values, then the exact power is given by the noncentral $F$ distribution. The noncentrality parameter is

\[
\lambda = N \frac{\rho^2_{XY|X_{-1}}}{1 - \rho^2_{Y|X_{-1}}}
\]

or equivalently,

\[
\lambda = N \frac{\rho^2_Y((X_1,X_{-1}) - \rho^2_Y|X_{-1})}{1 - \rho^2_Y((X_1,X_{-1})}
\]

The power is

\[
\text{power} = \begin{cases} 
P \left( F(p_1, N - 1 - p, \lambda) \geq F_{1-\alpha}(p_1, N - 1 - p) \right), & \text{intercept} \\
P \left( F(p_1, N - p, \lambda) \geq F_{1-\alpha}(p_1, N - p) \right), & \text{no intercept}
\end{cases}
\]

The minimum acceptable input value of $N$ depends on several factors, as shown in Table 57.26.

**Analyses in the ONECORR Statement**

Fisher’s z Test for Pearson Correlation (TEST=PEARSON DIST=FISHERZ)

Fisher’s z transformation (Fisher 1921) of the sample correlation \( R_{Y|(X_1,X_{-1})} \) is defined as

\[
z = \frac{1}{2} \log \left( \frac{1 + R_{Y|(X_1,X_{-1})}}{1 - R_{Y|(X_1,X_{-1})}} \right)
\]

Fisher’s z test assumes the approximate normal distribution \( N(\mu, \sigma^2) \) for \( z \), where

\[
\mu = \frac{1}{2} \log \left( \frac{1 + \rho_{Y|(X_1,X_{-1})}}{1 - \rho_{Y|(X_1,X_{-1})}} \right) + \frac{\rho_{Y|(X_1,X_{-1})}}{2(N - 1 - p^*)}
\]

and

\[
\sigma^2 = \frac{1}{N - 3 - p^*}
\]

where \( p^* \) is the number of variables partialled out (Anderson 1984, pp. 132–133) and \( \rho_{Y|(X_1,X_{-1})} \) is the partial correlation between \( Y \) and \( X_1 \) adjusting for the set of zero or more variables \( X_{-1} \).

The test statistic

\[
z^* = (N - 3 - p^*)^{1/2} \left[ z - \frac{1}{2} \log \left( \frac{1 + \rho_0}{1 - \rho_0} \right) - \frac{\rho_0}{2(N - 1 - p^*)} \right]
\]

is assumed to have a normal distribution \( N(\delta, \nu) \) where \( \rho_0 \) is the null partial correlation and \( \delta \) and \( \nu \) are derived from section 16.33 of Stuart and Ord (1994):

\[
\delta = (N - 3 - p^*)^{1/2} \left[ \frac{1}{2} \log \left( \frac{1 + \rho_{Y|(X_1,X_{-1})}}{1 - \rho_{Y|(X_1,X_{-1})}} \right) + \frac{\rho_{Y|(X_1,X_{-1})}}{2(N - 1 - p^*)} \left( 1 + \frac{5 + \rho_{Y|(X_1,X_{-1})}^2}{4(N - 1 - p^*)} + \frac{11 + 2\rho_{Y|(X_1,X_{-1})}^2 + 3\rho_{Y|(X_1,X_{-1})}^4}{8(N - 1 - p^*)^2} \right) \right]
\]
The approximate power is computed as
\[
\nu = \frac{N - 3 - p^*}{N - 1 - p^*} \left[ 1 + \frac{4 - \rho^2_{Y1,X-1}}{2(N - 1 - p^*)} + \frac{22 - 6\rho^2_{Y1,X-1} - 3\rho^4_{Y1,X-1}}{6(N - 1 - p^*)^2} \right]
\]

The approximate power is computed as
\[
\text{power} = \begin{cases} \Phi \left( \frac{\delta - z_{1-\alpha}}{\nu^2} \right), & \text{upper 1-sided} \\ \Phi \left( \frac{-\delta - z_{1-\alpha}}{\nu^2} \right), & \text{lower 1-sided} \\ \Phi \left( \frac{\delta - z_{1-\frac{\alpha}{2}}}{\nu^2} \right) + \Phi \left( \frac{-\delta - z_{1-\frac{\alpha}{2}}}{\nu^2} \right), & \text{2-sided} \end{cases}
\]

Because the test is biased, the achieved significance level may differ from the nominal significance level. The actual alpha is computed in the same way as the power except with the correlation \( \rho_Y|_{(X_1, X_{-1})} \) replaced by the null correlation \( \rho_0 \).

**t Test for Pearson Correlation (TEST=PEARSON DIST=T)**

The 2-sided case is identical to multiple regression with an intercept and \( p_1 = 1 \), which is discussed in the “Analyses in the MULTREG Statement” section on page 3500.

Let \( p^* \) denote the number of variables partialled out. For the 1-sided cases, the test statistic is
\[
t = (N - 2 - p^*)^{\frac{1}{2}} \frac{R_{Y1,X-1}}{\left(1 - R^2_{Y1,X-1}\right)^{\frac{1}{2}}}
\]

which is assumed to have a null distribution of \( t(N - 2 - p^*) \).

If the \( X \) and \( Y \) variables are assumed to have a joint multivariate normal distribution, then the exact power is given by the following formula:
\[
\text{power} = \begin{cases} P \left[ (N - 2 - p^*)^{\frac{1}{2}} \frac{R_{Y1,X-1}}{\left(1 - R^2_{Y1,X-1}\right)^{\frac{1}{2}}} \geq t_{1-\alpha}(N - 2 - p^*) \right], & \text{upper 1-sided} \\ P \left[ (N - 2 - p^*)^{\frac{1}{2}} \frac{R_{Y1,X-1}}{\left(1 - R^2_{Y1,X-1}\right)^{\frac{1}{2}}} \leq t_{\alpha}(N - 2 - p^*) \right], & \text{lower 1-sided} \end{cases}
\]
The distribution of \( R_Y \) given \( Y \) is given in Chapter 32 of Johnson, Kotz, and Balakrishnan (1995). If the \( X \) variables are assumed to have fixed values, then the exact power is given by the noncentral \( t \) distribution \( t(N - 2 - p^*, \delta) \), where the noncentrality is

\[
\delta = N^{\frac{1}{2}} \frac{\rho_{YX} | X_{-1}}{(1 - \rho_{YX}^2)}^{\frac{1}{2}}
\]

The power is

\[
\text{power} = \begin{cases} 
P(t(N - 2 - p^*, \delta) \geq t_{1-\alpha}(N - 2 - p^*)) , & \text{upper 1-sided} \\
\frac{1}{2} - P(t(N - 2 - p^*, \delta) \leq t_\alpha(N - 2 - p^*)) , & \text{lower 1-sided}
\end{cases}
\]

**Analyses in the ONESAMPLEFREQ Statement**

**Exact Test of a Binomial Proportion (TEST=EXACT)**

Let \( X \) be distributed as \( \text{Bin}(N, p) \). The hypotheses for the test of the proportion \( p \) are as follows:

\[
H_0 : p = p_0 \\
H_1 : \begin{cases} 
p \neq p_0 , & \text{2-sided} \\
p > p_0 , & \text{upper 1-sided} \\
p < p_0 , & \text{lower 1-sided}
\end{cases}
\]

The exact test assumes binomially distributed data and requires \( N \geq 1 \) and \( 0 < p_0 < 1 \). The test statistic is

\[
X = \text{number of successes} \sim \text{Bin}(N, p)
\]

The significance probability \( \alpha \) is split symmetrically for 2-sided tests, in the sense that each tail is filled with as much as possible up to \( \alpha/2 \).

Exact power computations are based on the binomial distribution and computing formulas such as the following from Johnson and Kotz (1970, equation 3.20):

\[
P(X \geq C | N, p) = P \left( F_{\nu_1, \nu_2} \leq \frac{\nu_2 p}{\nu_1 (1 - p)} \right)
\]

where \( \nu_1 = 2C \) and \( \nu_2 = 2(N - C + 1) \).
Let $C_L$ and $C_U$ denote lower and upper critical values, respectively. Let $\alpha_a$ denote the achieved (actual) significance level, which for 2-sided tests is the sum of the favorable major tail ($\alpha_M$) and the opposite minor tail ($\alpha_m$).

For the upper 1-sided case,
\[
C_U = \min \{ C : P(X \geq C | p_0) \leq \alpha \}
\]
Reject $H_0$ if $X \geq C_U$
\[
\alpha_a = P(X \geq C_U | p_0)
\]
\[
\text{power} = P(X \geq C_U | p)
\]

For the lower 1-sided case,
\[
C_L = \max \{ C : P(X \leq C | p_0) \leq \alpha \}
\]
Reject $H_0$ if $X \leq C_L$
\[
\alpha_a = P(X \leq C_L | p_0)
\]
\[
\text{power} = P(X \leq C_L | p)
\]

For the 2-sided case,
\[
C_L = \max \{ C : P(X \leq C | p_0) \leq \frac{\alpha}{2} \}
\]
\[
C_U = \min \{ C : P(X \geq C | p_0) \leq \frac{\alpha}{2} \}
\]
Reject $H_0$ if $X \leq C_L$ or $X \geq C_U$
\[
\alpha_a = P(X \leq C_L \text{ or } X \geq C_U | p_0)
\]
\[
\text{power} = P(X \leq C_L \text{ or } X \geq C_U | p)
\]

**z Test for Binomial Proportion (TEST=Z)**

For the normal approximation test, the test statistic is
\[
Z(X) = \frac{X - Np_0}{\sqrt{Np_0(1 - p_0)}}
\]

For the METHOD=EXACT option, the computations are the same as described in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504 except for the definitions of the critical values.

For the upper 1-sided case,
\[
C_U = \min \{ C : Z(C) \geq z_{1-\alpha} \}
\]

For the lower 1-sided case,
\[
C_L = \max \{ C : Z(C) \leq z_\alpha \}
For the 2-sided case,

\[
C_L = \max\{C : Z(C) \leq z_{\alpha/2}\} \\
C_U = \min\{C : Z(C) \geq z_{1-\alpha/2}\}
\]

For the METHOD=NORMAL option, the test statistic \(Z(X)\) is assumed to have the normal distribution

\[
N\left(\frac{N^{1/2}(p - p_0)}{[p_0(1-p_0)]^{1/2}}, \frac{p(1-p)}{p_0(1-p_0)}\right)
\]

The approximate power is computed as

\[
\text{power} = \begin{cases} 
\Phi\left(\frac{z_\alpha + \sqrt{N} \cdot \frac{p - p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{p(1-p)}}\right), & \text{upper 1-sided} \\
\Phi\left(\frac{z_\alpha - \sqrt{N} \cdot \frac{p - p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{p(1-p)}}\right), & \text{lower 1-sided} \\
\Phi\left(\frac{z_{\alpha/2} + \sqrt{N} \cdot \frac{p - p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{p(1-p)}}\right) + \Phi\left(\frac{-z_{\alpha/2} + \sqrt{N} \cdot \frac{p - p_0}{\sqrt{p_0(1-p_0)}}}{\sqrt{p(1-p)}}\right), & \text{2-sided}
\end{cases}
\]

The approximate sample size is computed in closed form for the 1-sided cases by inverting the power equation,

\[
N = \left(\frac{z_{\text{power}} \sqrt{p(1-p)} + z_{1-\alpha} \sqrt{p_0(1-p_0)}}{p - p_0}\right)^2
\]

and by numerical inversion for the 2-sided case.

**z Test for Binomial Proportion with Continuity Adjustment (TEST=ADJZ)**

For the normal approximation test with continuity adjustment, the test statistic is (Pagano and Gauvreau 1993 p. 295):

\[
Z_c(X) = \frac{X - Np_0 + 0.5(1\{X<Np_0\}) - 0.5(1\{X>Np_0\})}{[Np_0(1-p_0)]^{1/2}}
\]

For the METHOD=EXACT option, the computations are the same as described in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504 except for the definitions of the critical values.

For the upper 1-sided case,

\[
C_U = \min\{C : Z_c(C) \geq z_{1-\alpha}\}
\]
For the lower 1-sided case,
\[ C_L = \max \{ C : Z_c(C) \leq z_\alpha \} \]

For the 2-sided case,
\[ C_L = \max \{ C : Z_c(C) \leq z_{\alpha/2} \} \]
\[ C_U = \min \{ C : Z_c(C) \geq z_{1-\alpha/2} \} \]

For the METHOD=NORMAL option, the test statistic \( Z_c(X) \) is assumed to have the normal distribution \( N(\mu, \sigma^2) \) where \( \mu \) and \( \sigma^2 \) are derived as follows.

For convenience of notation, define
\[ k = \frac{1}{2\sqrt{Np_0(1 - p_0)}} \]

Then
\[ E[Z_c(X)] = 2kNp - 2kNp_0 + kP(X < Np_0) - kP(X > Np_0) \]
and
\[ \text{Var}[Z_c(X)] = \frac{p(1 - p)}{p_0(1 - p_0)} + k^2 [1 - P(X = Np_0)] \\
- k^2 [P(X < Np_0) - P(X > Np_0)]^2 \\
+ 4k^2 \left[ E(X1_{\{X < Np_0\}}) - E(X1_{\{X > Np_0\}}) \right] \\
- 4k^2 Np \left[ P(X < Np_0) - P(X > Np_0) \right] \]

The probabilities \( P(X = Np_0) \), \( P(X < Np_0) \), and \( P(X > Np_0) \) and the truncated expectations \( E(X1_{\{X < Np_0\}}) \) and \( E(X1_{\{X > Np_0\}}) \) are approximated by assuming the normal-approximate distribution of \( X \), \( N(Np, Np(1 - p)) \). Letting \( \phi(\cdot) \) and \( \Phi(\cdot) \) denote the standard normal PDF and CDF, respectively, and defining \( d \) as
\[ d = \frac{Np_0 - Np}{[Np(1 - p)]^{1/2}} \]

the terms are computed as follows:
\[ P(X = Np_0) = 0 \]
\[ P(X < Np_0) = \Phi(d) \]
The mean and variance of \( Z_c(X) \) are thus approximated by

\[
\mu = k \left[ 2Np - 2Np_0 + 2\Phi(d) - 1 \right]
\]

and

\[
\sigma^2 = 4k^2 \left[ Np(1 - p) + \Phi(d) (1 - \Phi(d)) - 2 (Np(1 - p))^{\frac{3}{2}} \phi(d) \right]
\]

The approximate power is computed as

\[
\text{power} = \begin{cases} 
\Phi \left( \frac{z_\alpha + \mu}{\sigma} \right), & \text{upper 1-sided} \\
\Phi \left( \frac{z_\alpha - \mu}{\sigma} \right), & \text{lower 1-sided} \\
\Phi \left( \frac{z_\alpha - \mu}{\sigma} \right) + \Phi \left( \frac{z_\alpha + \mu}{\sigma} \right), & \text{2-sided}
\end{cases}
\]

**Analyses in the ONESAMPLEMEANS Statement**

**One-sample t Test (TEST=T)**

The hypotheses for the one-sample \( t \) test are

\[
H_0 : \mu = \mu_0 \\
H_1 : \begin{cases} 
\mu \neq \mu_0, & \text{2-sided} \\
\mu > \mu_0, & \text{upper 1-sided} \\
\mu < \mu_0, & \text{lower 1-sided}
\end{cases}
\]

The test assumes normally distributed data and requires \( N \geq 2 \). The test statistics are

\[
t = N^{\frac{1}{2}} \left( \frac{\bar{x} - \mu_0}{s} \right) \sim t(N - 1, \delta)
\]

\[
t^2 \sim F(1, N - 1, \delta^2)
\]

where \( \bar{x} \) is the sample mean, \( s \) is the sample standard deviation, and

\[
\delta = N^{\frac{1}{2}} \left( \frac{\mu - \mu_0}{\sigma} \right)
\]
The test is

\[
\text{Reject } H_0 \text{ if } \begin{cases} 
    t^2 \geq F_{1-\alpha}(1, N - 1), & \text{2-sided} \\
    t \geq t_{1-\alpha}(N - 1), & \text{upper 1-sided} \\
    t \leq t_{\alpha}(N - 1), & \text{lower 1-sided}
\end{cases}
\]

Exact power computations for \( t \) tests are discussed in O’Brien and Muller (1993, section 8.2), although not specifically for the one-sample case. The power is based on the noncentral \( t \) and \( F \) distributions:

\[
\begin{align*}
\text{power} &= \begin{cases} 
    P \left( F(1, N - 1, \delta^2) \geq F_{1-\alpha}(1, N - 1) \right), & \text{2-sided} \\
    P \left( t(N - 1, \delta) \geq t_{1-\alpha}(N - 1) \right), & \text{upper 1-sided} \\
    P \left( t(N - 1, \delta) \leq t_{\alpha}(N - 1) \right), & \text{lower 1-sided}
\end{cases}
\end{align*}
\]

Solutions for \( N, \alpha, \) and \( \delta \) are obtained by numerically inverting the power equation. Closed-form solutions for other parameters, in terms of \( \delta \), are as follows:

\[
\begin{align*}
\mu &= \delta \sigma N^{-\frac{1}{2}} + \mu_0 \\
\sigma &= \begin{cases} 
    \delta^{-1} N^{\frac{1}{2}} (\mu_0 - \mu), & |\delta| > 0 \\
    \text{undefined}, & \text{otherwise}
\end{cases}
\end{align*}
\]

One-sample t Test with Lognormal Data (TEST=T DIST=LOGNORMAL)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “One-sample t Test (TEST=T)” section on page 3508 then apply.

In contrast to the usual \( t \) test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. This is because the transformation of a null arithmetic mean of lognormal data to the normal scale depends on the unknown coefficient of variation, resulting in an ill-defined hypothesis on the log-transformed data. Geometric means transform cleanly and are more natural for lognormal data.

The hypotheses for the one-sample \( t \) test with lognormal data are

\[
\begin{align*}
H_0 : \quad & \gamma = 1 \\
H_1 : & \begin{cases} 
    \frac{\gamma}{\gamma_0} \neq 1, & \text{2-sided} \\
    \frac{\gamma}{\gamma_0} > 1, & \text{upper 1-sided} \\
    \frac{\gamma}{\gamma_0} < 1, & \text{lower 1-sided}
\end{cases}
\end{align*}
\]
Let $\mu^*$ and $\sigma^*$ be the (arithmetic) mean and standard deviation of the normal distribution of the log-transformed data. The hypotheses can be rewritten as follows:

$$H_0 : \mu^* = \log(\gamma_0)$$

$$H_1 : \begin{cases} 
\mu^* \neq \log(\gamma_0), & \text{2-sided} \\
\mu^* > \log(\gamma_0), & \text{upper 1-sided} \\
\mu^* < \log(\gamma_0), & \text{lower 1-sided}
\end{cases}$$

where $\mu^* = \log(\gamma)$.

The test assumes lognormally distributed data and requires $N \geq 2$.

The power is

$$\text{power} = \begin{cases} 
P \left( F(1, N - 1, \delta^2) \geq F_{1-\alpha}(1, N - 1) \right), & \text{2-sided} \\
P \left( t(N - 1, \delta) \geq t_{1-\alpha}(N - 1) \right), & \text{upper 1-sided} \\
P \left( t(N - 1, \delta) \leq t_{\alpha}(N - 1) \right), & \text{lower 1-sided}
\end{cases}$$

where

$$\delta = N^{\frac{1}{2}} \left( \frac{\mu^* - \log(\gamma_0)}{\sigma^*} \right)$$

$$\sigma^* = \left[ \log(CV^2 + 1) \right]^\frac{1}{2}$$

### Equivalence Test for Mean of Normal Data (TEST=EQUIV DIST=NORMAL)

The hypotheses for the equivalence test are

$$H_0 : \mu < \theta_L \text{ or } \mu > \theta_U$$

$$H_1 : \theta_L \leq \mu \leq \theta_U$$

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires $N \geq 2$. Phillips (1990) derives an expression for the exact power assuming a two-sample balanced design; the results are easily adapted to a one-sample design:

$$\text{power} = Q_{N-1} \left( \frac{\mu - \theta_U}{\sigma N^{-\frac{1}{2}}}; 0, \frac{(N - 1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(t_{1-\alpha}(N - 1))} \right) - Q_{N-1} \left( \frac{\mu - \theta_L}{\sigma N^{-\frac{1}{2}}}; 0, \frac{(N - 1)^{\frac{1}{2}}(\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}}(t_{1-\alpha}(N - 1))} \right)$$

where $Q(\cdot; \cdot; \cdot; \cdot)$ is Owen’s Q function, defined in the “Common Notation” section on page 3498.
Equivalence Test for Mean of Lognormal Data (TEST=EQUIV DIST=LOGNORMAL)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Equivalence Test for Mean of Normal Data (TEST=EQUIV DIST=NORMAL)” section on page 3510 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. This is because the transformation of an arithmetic mean of lognormal data to the normal scale depends on the unknown coefficient of variation, resulting in an ill-defined hypothesis on the log-transformed data. Geometric means transform cleanly and are more natural for lognormal data.

The hypotheses for the equivalence test are

\[ H_0 : \gamma \leq \theta_L \text{ or } \gamma \geq \theta_U \]
\[ H_1 : \theta_L < \gamma < \theta_U \]

where \(0 < \theta_L < \theta_U\)

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires \(N \geq 2\). Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to a one-sample design:

\[
\text{power} = Q_{N-1} \left(\left(-t_{1-\alpha}(N-1)\right), \frac{\log(\gamma) - \log(\theta_U)}{\sigma^* N^{1/2}}; \right.
\left.0, \frac{(N-1)^{1/2} (\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{1/2} (t_{1-\alpha}(N-1))}\right) -
\]
\[
Q_{N-1} \left((t_{1-\alpha}(N-1)), \frac{\log(\gamma) - \log(\theta_L)}{\sigma^* N^{1/2}}; \right.
\left.0, \frac{(N-1)^{1/2} (\log(\theta_U) - \log(\theta_L))}{2\sigma^* N^{1/2} (t_{1-\alpha}(N-1))}\right)
\]

where

\[ \sigma^* = \left[\log(CV^2 + 1)\right]^{1/2} \]

is the standard deviation of the log-transformed data, and \(Q_{(.; \cdot; \cdot; \cdot)}\) is Owen’s Q function, defined in the “Common Notation” section on page 3498.
Confidence Interval for Mean (CI=T)

This analysis of precision applies to the standard $t$-based confidence interval:

$$
\left[ \bar{x} - t_{1-\frac{\alpha}{2}} \left( N - 1 \right) \frac{s}{\sqrt{N}}, \ \bar{x} + t_{1-\frac{\alpha}{2}} \left( N - 1 \right) \frac{s}{\sqrt{N}} \right], \ \text{2-sided}
$$

$$
\left[ \bar{x} - t_{1-\alpha} \left( N - 1 \right) \frac{s}{\sqrt{N}}, \ \infty \right], \ \text{upper 1-sided}
$$

$$
\left[ -\infty, \ \bar{x} + t_{1-\alpha} \left( N - 1 \right) \frac{s}{\sqrt{N}} \right], \ \text{lower 1-sided}
$$

where $\bar{x}$ is the sample mean and $s$ is the sample standard deviation. The “half-width” is defined as the distance from the point estimate $\bar{x}$ to a finite endpoint,

$$
\text{half-width} = \begin{cases} 
  t_{1-\frac{\alpha}{2}} \left( N - 1 \right) \frac{s}{\sqrt{N}}, & \text{2-sided} \\
  t_{1-\alpha} \left( N - 1 \right) \frac{s}{\sqrt{N}}, & \text{1-sided}
\end{cases}
$$

A “valid” confidence interval captures the true mean. The exact probability of obtaining at most the target confidence interval half-width $h$, unconditional or conditional on validity, is given by Beal (1989):

$$
\Pr(\text{half-width} \leq h) = \begin{cases} 
  P \left( \chi^2(N - 1) \leq \frac{h^2N(N-1)}{\sigma^2(t_{1-\frac{\alpha}{2}}(N-1))} \right), & \text{2-sided} \\
  P \left( \chi^2(N - 1) \leq \frac{h^2N(N-1)}{\sigma^2(t_{1-\alpha}(N-1))} \right), & \text{1-sided}
\end{cases}
$$

$$
\Pr(\text{half-width} \leq h \mid \text{validity}) = \begin{cases} 
  \left( \frac{1}{1-\alpha} \right) 2 \left[ Q_{N-1} \left( (t_{1-\frac{\alpha}{2}}(N - 1)), 0; 0, b_1 \right) - Q_{N-1}(0, 0; 0, b_1) \right], & \text{2-sided} \\
  \left( \frac{1}{1-\alpha} \right) Q_{N-1} \left( (t_{1-\alpha}(N - 1)), 0; 0, b_1 \right), & \text{1-sided}
\end{cases}
$$

where

$$
b_1 = \frac{h(N - 1)^{\frac{3}{2}}}{\sigma(t_{1-\frac{\alpha}{2}}(N - 1))N^{-\frac{1}{2}}}
$$

$$
c = \text{number of sides}
$$

and $Q(\cdot, \cdot; \cdot, \cdot)$ is Owen’s Q function, defined in the “Common Notation” section on page 3498.

A “quality” confidence interval is both sufficiently narrow (half-width $\leq h$) and valid:

$$
\Pr(\text{quality}) = \Pr(\text{half-width} \leq h \text{ and validity}) \quad = \quad \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha)
$$
Analyses in the ONEWAYANOVA Statement

One-Degree-of-Freedom Contrast (TEST=CONTRAST)

The hypotheses are

\[ H_0 : c_1 \mu_1 + \cdots + c_G \mu_G = c_0 \]
\[ H_1 : \begin{cases} c_1 \mu_1 + \cdots + c_G \mu_G \neq c_0, & \text{2-sided} \\ c_1 \mu_1 + \cdots + c_G \mu_G > c_0, & \text{upper 1-sided} \\ c_1 \mu_1 + \cdots + c_G \mu_G < c_0, & \text{lower 1-sided} \end{cases} \]

where \( G \) is the number of groups, \( \{c_1, \ldots, c_G\} \) are the contrast coefficients, and \( c_0 \) is the null contrast value.

The test is the usual \( F \) test for a contrast in one-way ANOVA. It assumes normal data with common group variances and requires \( N \geq G + 1 \) and \( n_i \geq 1 \).

O’Brien and Muller (1993, section 8.2.3.2) give the exact power as

\[ \text{power} = \begin{cases} P \left( F(1, N - G, \delta^2) \geq F_{1-\alpha}(1, N - G) \right), & \text{2-sided} \\ P \left( t(N - G, \delta) \geq t_{1-\alpha}(N - G) \right), & \text{upper 1-sided} \\ P \left( t(N - G, \delta) \leq t_{\alpha}(N - G) \right), & \text{lower 1-sided} \end{cases} \]

where

\[ \delta = N^{\frac{1}{4}} \left( \frac{\sum_{i=1}^{G} c_i \mu_i - c_0}{\sigma \left( \sum_{i=1}^{G} c_i^2 w_i \right)^{\frac{1}{2}}} \right) \]

Overall F Test (TEST=OVERALL)

The hypotheses are

\[ H_0 : \mu_1 = \mu_2 = \cdots = \mu_G \]
\[ H_1 : \mu_i \neq \mu_j \text{ for some } i, j \]

where \( G \) is the number of groups.

The test is the usual overall \( F \) test for equality of means in one-way ANOVA. It assumes normal data with common group variances and requires \( N \geq G + 1 \) and \( n_i \geq 1 \).

O’Brien and Muller (1993, section 8.2.3.1) give the exact power as

\[ \text{power} = P \left( F(G - 1, N - G, \lambda) \geq F_{1-\alpha}(G - 1, N - G) \right) \]
where the noncentrality is

\[ \lambda = N \left( \frac{\sum_{i=1}^{G} w_i (\mu_i - \bar{\mu})^2}{\sigma^2} \right) \]

and

\[ \bar{\mu} = \sum_{i=1}^{G} w_i \mu_i \]

</table>

All McNemar tests covered in PROC POWER are *conditional*, meaning that \( n_D \) is assumed fixed at its observed value.
For the usual \( OR_0 = 0 \), the hypotheses are

\[
H_0 : \quad \pi_1 = \pi_1.
\]

\[
H_1 : \begin{cases} 
\pi_1 \neq \pi_1, & \text{2-sided} \\
\pi_1 > \pi_1, & \text{upper 1-sided} \\
\pi_1 < \pi_1, & \text{lower 1-sided}
\end{cases}
\]

The test statistic for both tests covered in PROC POWER (DIST=EXACT_COND and DIST=NORMAL) is the McNemar statistic \( Q_M \), which has the following form when \( OR_0 = 0 \):

\[
Q_{M_0} = \frac{(n_{01} - n_{10})^2}{n_{01} + n_{10}}
\]

For the conditional McNemar tests, this is equivalent to the square of the \( Z(X) \) statistic for the test of a single proportion (normal approximation to binomial), where the proportion is \( \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \), the null is 0.5, and “\( N \)” is \( n_D \) (see, e.g., Schork and Williams 1980):

\[
Z(X) = \frac{n_{01} - n_D(0.5)}{[n_D0.5(1 - 0.5)]^{\frac{1}{2}}} \approx N \left( n_D^\frac{1}{2} \left( \frac{\pi_{01}}{\pi_{01} + \pi_{10}} - 0.5 \right), \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \left( 1 - \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \right) \right)
\]

\[
= \frac{n_{01} - (n_{01} + n_{10})(0.5)}{[(n_{01} + n_{10})0.5(1 - 0.5)]^{\frac{1}{2}}}
\]

\[
= \frac{n_{01} - n_{10}}{[n_{01} + n_{10}]^{\frac{1}{2}}}
\]

\[
= \sqrt{Q_{M_0}}
\]

This can be generalized to a custom null for \( \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \), which is equivalent to specifying a custom odds ratio:

\[
\left[ \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \right]_0 \equiv \left[ \frac{1}{1 + \frac{\pi_{01}}{\pi_{10}}} \right]_0 \equiv \frac{1}{1 + OR_0}
\]

So, a conditional McNemar test (asymptotic or exact) with a custom null is equivalent to the test of a single proportion \( p_1 \equiv \frac{\pi_{01}}{\pi_{01} + \pi_{10}} \) with a null value \( p_0 \equiv \frac{1}{1 + OR_0} \), with a sample size of \( n_D \):

\[
H_0 : \quad p_1 = p_0
\]

\[
H_1 : \begin{cases} 
\ p_1 \neq p_0, & \text{2-sided} \\
\ p_1 > p_0, & \text{1-sided U} \\
\ p_1 < p_0, & \text{1-sided L}
\end{cases}
\]
which is equivalent to

$$H_0 : \text{OR} = \text{OR}_0$$

$$H_1 : \begin{cases} \text{OR} \neq \text{OR}_0, & \text{2-sided} \\ \text{OR} > \text{OR}_0, & \text{1-sided U} \\ \text{OR} < \text{OR}_0, & \text{1-sided L} \end{cases}$$

The general form of the test statistic is thus

$$Q_M = \frac{(n_{01} - n_Dp_0)^2}{n_Dp_0(1 - p_0)}$$

The two most common conditional McNemar tests assume either the exact conditional distribution of $Q_M$ (covered by the DIST=EXACT–COND analysis) or a standard normal distribution for $Q_M$ (covered by the DIST=NORMAL analysis).

**McNemar Exact Conditional Test (TEST=MCNEMAR DIST=EXACT–COND)**

For DIST=EXACT–COND, the power is calculated assuming that the test is conducted using the exact conditional distribution of $Q_M$ (conditional on $n_D$). The power is calculated by first computing the conditional power for each possible $n_D$. The unconditional power is computed as a weighted average over all possible outcomes of $n_D$:

$$\text{power} = \sum_{n_D=0}^{N} P(n_D)P(\text{Reject } p_1 = p_0|n_D)$$

where $n_D \sim \text{Bin}(\pi_{01} + \pi_{10}, N)$, and $P(\text{Reject } p_1 = p_0|n_D)$ is calculated using the exact method in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504.

The achieved significance level, reported as Actual Alpha in the analysis, is computed in the same way except using the actual alpha of the one-sample test in place of its power:

$$\text{actual alpha} = \sum_{n_D=0}^{N} P(n_D)\alpha^*(p_1, p_0|n_D)$$

where $\alpha^*(p_1, p_0|n_D)$ is the actual alpha calculated using the exact method in the “Exact Test of a Binomial Proportion (TEST=EXACT)” section on page 3504 with proportion $p_1$, null $p_0$, and sample size $n_D$. 
McNemar Normal Approximation Test ($\text{TEST=MCNEMAR DIST=NORMAL}$)

For $\text{DIST=NORMAL}$, power is calculated assuming the test is conducted using the normal-approximate distribution of $Q_M$ (conditional on $n_D$).

For the METHOD=EXACT option, the power is calculated in the same way as described in the “McNemar Exact Conditional Test ($\text{TEST=MCNEMAR DIST=EXACT\_COND}$)” section on page 3516, except that $P(\text{Reject } p_1 = p_0 | n_D)$ is calculated using the exact method in the “$z$ Test for Binomial Proportion ($\text{TEST=Z}$)” section on page 3505. The achieved significance level is calculated in the same way as described at the end of the “McNemar Exact Conditional Test ($\text{TEST=MCNEMAR DIST=EXACT\_COND}$)” section on page 3516.

For the METHOD=MIETTINEN option, approximate sample size for the 1-sided cases is computed according to equation (5.6) in Miettinen (1968):

$$\displaystyle N = \left\{ z_{1-\alpha} (p_{10} + p_{01}) + z_{\text{power}} \left[ (p_{10} + p_{01})^2 - \frac{1}{4} (p_{01} - p_{10})^2 (3 + p_{10} + p_{01}) \right] \right\}^2 \left( \frac{z_{\text{power}}}{(z_{\text{power}})^2 + (p_{01} - p_{10})^2} \right)$$

Approximate power for the 1-sided cases is computed by solving the sample size equation for power, and approximate power for the 2-sided case follows easily by summing the 1-sided powers each at $\alpha / 2$:

$$\displaystyle \text{power} = \begin{cases} \Phi \left( \frac{(p_{01} - p_{10}) [N (p_{10} + p_{01})]^{1/2} - z_{1-\alpha} (p_{10} + p_{01})}{(p_{10} + p_{01})^2 - \frac{1}{4} (p_{01} - p_{10})^2 (3 + p_{10} + p_{01})} \right), & \text{upper 1-sided} \\
\Phi \left( -\frac{(p_{01} - p_{10}) [N (p_{10} + p_{01})]^{1/2} - z_{1-\alpha} (p_{10} + p_{01})}{(p_{10} + p_{01})^2 - \frac{1}{4} (p_{01} - p_{10})^2 (3 + p_{10} + p_{01})} \right), & \text{lower 1-sided} \\
\Phi \left( \frac{(p_{01} - p_{10}) [N (p_{10} + p_{01})]^{1/2} - z_{1-\alpha} (p_{10} + p_{01})}{(p_{10} + p_{01})^2 - \frac{1}{4} (p_{01} - p_{10})^2 (3 + p_{10} + p_{01})} + \Phi \left( -\frac{(p_{01} - p_{10}) [N (p_{10} + p_{01})]^{1/2} - z_{1-\alpha} (p_{10} + p_{01})}{(p_{10} + p_{01})^2 - \frac{1}{4} (p_{01} - p_{10})^2 (3 + p_{10} + p_{01})} \right) \right), & \text{2-sided} 
\end{cases}$$

The 2-sided solution for $N$ is obtained by numerically inverting the power equation.

In general, compared to METHOD=CONNOR, the METHOD=MIETTINEN approximation tends to be slightly more accurate but may be slightly anticonservative in the sense of underestimating sample size and overestimating power (Lachin 1992, p. 1250).

For the METHOD=CONNOR option, approximate sample size for the 1-sided cases is computed according to equation (3) in Connor (1987):

$$\displaystyle N = \left\{ z_{1-\alpha} (p_{10} + p_{01})^{1/2} + z_{\text{power}} \left[ p_{10} + p_{01} - (p_{01} - p_{10})^2 \right]^{1/2} \right\}^2 \left( \frac{z_{\text{power}}}{(z_{\text{power}})^2 + (p_{01} - p_{10})^2} \right)$$
Approximate power for the 1-sided cases is computed by solving the sample size equation for power, and approximate power for the 2-sided case follows easily by summing the 1-sided powers each at \( \alpha/2 \):

\[
power = \begin{cases} 
\Phi \left( \frac{(p_{01} - p_{10}) N^{\frac{1}{2}} - z_{1 - \alpha} (p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right), & \text{upper 1-sided} \\
\Phi \left( \frac{- (p_{01} - p_{10}) N^{\frac{1}{2}} - z_{1 - \alpha} (p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right), & \text{lower 1-sided} \\
\Phi \left( \frac{(p_{01} - p_{10}) N^{\frac{1}{2}} - z_{1 - \alpha} (p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right) + \Phi \left( \frac{- (p_{01} - p_{10}) N^{\frac{1}{2}} - z_{1 - \alpha} (p_{10} + p_{01})^{\frac{1}{2}}}{[p_{10} + p_{01} - (p_{01} - p_{10})^2]^{\frac{1}{2}}} \right), & \text{2-sided} 
\end{cases}
\]

The 2-sided solution for \( N \) is obtained by numerically inverting the power equation.

In general, compared to METHOD=MIEITTINEN, the METHOD=CONNOR approximation tends to be slightly less accurate but slightly conservative in the sense of overestimating sample size and underestimating power (Lachin 1992, p. 1250).

### Analyses in the PAIREDMEANS Statement

**Paired t Test (TEST=DIFF)**

The hypotheses for the paired \( t \) test are

\[
H_0 : \mu_{\text{diff}} = \mu_0 \\
H_1 : \begin{cases} 
\mu_{\text{diff}} \neq \mu_0, & \text{2-sided} \\
\mu_{\text{diff}} > \mu_0, & \text{upper 1-sided} \\
\mu_{\text{diff}} < \mu_0, & \text{lower 1-sided}
\end{cases}
\]

The test assumes normally distributed data and requires \( N \geq 2 \). The test statistics are

\[
t = N^{\frac{1}{2}} \left( \frac{\bar{d} - \mu_0}{s_d} \right) \sim t(N - 1, \delta) \\
t^2 \sim F(1, N - 1, \delta^2)
\]

where \( \bar{d} \) and \( s_d \) are the sample mean and standard deviation of the differences and

\[
\delta = N^{\frac{1}{2}} \left( \frac{\mu_{\text{diff}} - \mu_0}{\sigma_{\text{diff}}} \right)
\]

and

\[
\sigma_{\text{diff}} = \left( \sigma_1^2 + \sigma_2^2 - 2 \rho \sigma_1 \sigma_2 \right)^{\frac{1}{2}}
\]
The test is

\[ \text{Reject } H_0 \text{ if } \begin{cases} t^2 \geq F_{1-\alpha}(1, N-1), & \text{2-sided} \\ t \geq t_{1-\alpha}(N-1), & \text{upper 1-sided} \\ t \leq t_\alpha(N-1), & \text{lower 1-sided} \end{cases} \]

Exact power computations for \( t \) tests are given in O’Brien and Muller (1993, section 8.2.2): 

\[ \text{power} = \begin{cases} P(F(1, N - 1, \delta^2) \geq F_{1-\alpha}(1, N - 1)), & \text{2-sided} \\ P(t(N - 1, \delta) \geq t_{1-\alpha}(N - 1)), & \text{upper 1-sided} \\ P(t(N - 1, \delta) \leq t_\alpha(N - 1)), & \text{lower 1-sided} \end{cases} \]

**Paired t Test for Mean Ratio with Lognormal Data (TEST=RATIO)**

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Paired t Test (TEST=DIFF)” section on page 3518 then apply.

In contrast to the usual \( t \) test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the paired \( t \) test with lognormal pairs \( \{Y_1, Y_2\} \) are 

\[ H_0 : \frac{\gamma_2}{\gamma_1} = \gamma_0 \]

\[ H_1 : \begin{cases} \frac{\gamma_2}{\gamma_1} \neq \gamma_0, & \text{2-sided} \\ \frac{\gamma_2}{\gamma_1} > \gamma_0, & \text{upper 1-sided} \\ \frac{\gamma_2}{\gamma_1} < \gamma_0, & \text{lower 1-sided} \end{cases} \]

Let \( \mu^*_1, \mu^*_2, \sigma^*_1, \sigma^*_2, \) and \( \rho^* \) be the (arithmetic) means, standard deviations, and correlation of the bivariate normal distribution of the log-transformed data \( \{\log Y_1, \log Y_2\} \). The hypotheses can be rewritten as follows:

\[ H_0 : \mu^*_2 - \mu^*_1 = \log(\gamma_0) \]

\[ H_1 : \begin{cases} \mu^*_2 - \mu^*_1 \neq \log(\gamma_0), & \text{2-sided} \\ \mu^*_2 - \mu^*_1 > \log(\gamma_0), & \text{upper 1-sided} \\ \mu^*_2 - \mu^*_1 < \log(\gamma_0), & \text{lower 1-sided} \end{cases} \]

where

\[ \mu^*_1 = \log \gamma_1 \]

\[ \mu^*_2 = \log \gamma_2 \]

\[ \sigma^*_1 = \sqrt{\log(CV^2_1 + 1)} \]
\[
\sigma_2^* = \left[ \log(CV_2^2 + 1) \right]^{\frac{1}{2}} \\
\rho^* = \frac{\log \{ \rho CV_1 CV_2 + 1 \}}{\sigma_1^* \sigma_2^*}
\]

and \(CV_1, CV_2,\) and \(\rho\) are the coefficients of variation and the correlation of the original untransformed pairs \(\{Y_1, Y_2\}\). The conversion from \(\rho\) to \(\rho^*\) is shown in Jones and Miller (1966).

The test assumes lognormally distributed data and requires \(N \geq 2\). The power is

\[
\text{power} = \begin{cases} 
P \left( F(1, N - 1, \delta^2) \geq F_{1-\alpha}(1, N - 1) \right), & \text{2-sided} \\
P \left( t(N - 1, \delta) \geq t_{1-\alpha}(N - 1) \right), & \text{upper 1-sided} \\
P \left( t(N - 1, \delta) \leq t_{\alpha}(N - 1) \right), & \text{lower 1-sided}
\end{cases}
\]

where

\[
\delta = N^{\frac{1}{2}} \left( \frac{\mu^*_1 - \mu^*_2 - \log(\gamma_0)}{\sigma^*} \right)
\]

and

\[
\sigma^* = \left( \sigma_1^*^2 + \sigma_2^*^2 - 2 \rho^* \sigma_1^* \sigma_2^* \right)^{\frac{1}{2}}
\]

**Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)**

The hypotheses for the equivalence test are

\[H_0 : \mu_{\text{diff}} < \theta_L \quad \text{or} \quad \mu_{\text{diff}} > \theta_U\]
\[H_1 : \theta_L \leq \mu_{\text{diff}} \leq \theta_U\]

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires \(N \geq 2\). Phillips (1990) derives an expression for the exact power assuming a two-sample balanced design; the results are easily adapted to a paired design:

\[
\text{power} = Q_{N-1} \left( -t_{1-\alpha}(N - 1), \frac{\mu_{\text{diff}} - \theta_U}{\sigma_{\text{diff}} N^{-\frac{1}{2}}}; 0, \frac{(N - 1)^{\frac{1}{2}} (\theta_U - \theta_L)}{2 \sigma_{\text{diff}} N^{-\frac{1}{2}} (t_{1-\alpha}(N - 1))} \right) -
\]

\[
Q_{N-1} \left( t_{1-\alpha}(N - 1), \frac{\mu_{\text{diff}} - \theta_L}{\sigma_{\text{diff}} N^{-\frac{1}{2}}}; 0, \frac{(N - 1)^{\frac{1}{2}} (\theta_U - \theta_L)}{2 \sigma_{\text{diff}} N^{-\frac{1}{2}} (t_{1-\alpha}(N - 1))} \right)
\]

where

\[
\sigma_{\text{diff}} = \left( \sigma_1^*^2 + \sigma_2^*^2 - 2 \rho \sigma_1 \sigma_2 \right)^{\frac{1}{2}}
\]

and \(Q(\cdot; \cdot; \cdot; \cdot)\) is Owen’s Q function, defined in the “Common Notation” section on page 3498.
Multiplicative Equivalence Test for Mean Ratio with Lognormal Data
(TEST=EQUIV_RATIO)

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV_DIFF)” section on page 3520 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the equivalence test are

\[
H_0 : \frac{\gamma_T}{\gamma_R} \leq \theta_L \quad \text{or} \quad \frac{\gamma_T}{\gamma_R} \geq \theta_U
\]

\[
H_1 : \theta_L < \frac{\gamma_T}{\gamma_R} < \theta_U
\]

where \( 0 < \theta_L < \theta_U \)

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on the log-transformed data. The test assumes lognormally distributed data and requires \( N \geq 2 \). Diletti, Hauschke, and Steinijans (1991) derive an expression for the exact power assuming a crossover design; the results are easily adapted to a paired design:

\[
\text{power} = Q_{N-1} \left( \left( -t_{1-\alpha} (N-1) \right) \frac{\log \left( \frac{\gamma_T}{\gamma_R} \right) - \log (\theta_U)}{\sigma^* N^{-\frac{1}{2}}} \right)
\]

\[
0, \left( N-1 \right)^{\frac{1}{2}} \left( \log (\theta_U) - \log (\theta_L) \right) - \frac{2 \sigma^* N^{-\frac{1}{2}} (t_{1-\alpha} (N-1))}{t_{1-\alpha} (N-1)}
\]

\[
Q_{N-1} \left( \left( t_{1-\alpha} (N-1) \right) \frac{\log \left( \frac{\gamma_T}{\gamma_R} \right) - \log (\theta_L)}{\sigma^* N^{-\frac{1}{2}}} \right)
\]

\[
0, \left( N-1 \right)^{\frac{1}{2}} \left( \log (\theta_U) - \log (\theta_L) \right) - \frac{2 \sigma^* N^{-\frac{1}{2}} (t_{1-\alpha} (N-1))}{t_{1-\alpha} (N-1)}
\]

where \( \sigma^* \) is the standard deviation of the differences between the log-transformed pairs (in other words, the standard deviation of \( \log(Y_T) - \log(Y_R) \)), where \( Y_T \) and \( Y_R \) are observations from the treatment and reference, respectively, computed as

\[
\sigma^* = \left( \sigma_R^2 + \sigma_T^2 - 2 \rho^* \sigma_R \sigma_T^* \right)^{\frac{1}{2}}
\]

\[
\sigma_R^* = \left[ \log \left( CV_R^2 + 1 \right) \right]^{\frac{1}{2}}
\]

\[
\sigma_T^* = \left[ \log \left( CV_T^2 + 1 \right) \right]^{\frac{1}{2}}
\]

\[
\rho^* = \frac{\log \left( \rho CV_R CV_T + 1 \right)}{\sigma_R \sigma_T^*}
\]
where \( CV_R, CV_T, \) and \( \rho \) are the coefficients of variation and the correlation of the original untransformed pairs \( \{Y_T, Y_R\} \), and \( Q(\cdot;\cdot;\cdot) \) is Owen’s Q function. The conversion from \( \rho \) to \( \rho^* \) is shown in Jones and Miller (1966), and Owen’s Q function is defined in the “Common Notation” section on page 3498.

Confidence Interval for Mean Difference (CI=DIFF)

This analysis of precision applies to the standard \( t \)-based confidence interval:

\[
\begin{align*}
\bar{d} - t_{1-\frac{\alpha}{2}} (N-1) \frac{s_d}{\sqrt{N}}, & \quad \bar{d} + t_{1-\frac{\alpha}{2}} (N-1) \frac{s_d}{\sqrt{N}}, \\ -\infty, & \quad \bar{d} + t_{1-\alpha} (N-1) \frac{s_d}{\sqrt{N}}, \\ \infty, & \quad \bar{d} - t_{1-\alpha} (N-1) \frac{s_d}{\sqrt{N}},
\end{align*}
\]

where \( \bar{d} \) and \( s_d \) are the sample mean and standard deviation of the differences. The “half-width” is defined as the distance from the point estimate \( \bar{d} \) to a finite endpoint,

\[
\text{half-width} = \begin{cases} 
  t_{1-\frac{\alpha}{2}} (N-1) \frac{s_d}{\sqrt{N}}, & \text{2-sided} \\
  t_{1-\alpha} (N-1) \frac{s_d}{\sqrt{N}}, & \text{1-sided}
\end{cases}
\]

A “valid” conference interval captures the true mean difference. The exact probability of obtaining at most the target confidence interval half-width \( h \), unconditional or conditional on validity, is given by Beal (1989):

\[
\Pr(\text{half-width} \leq h) = \begin{cases} 
  P \left( \chi^2(N-1) \leq \frac{h^2(N(N-1))}{\sigma^2_{\text{diff}}(t_{1-\frac{\alpha}{2}} (N-1))} \right), & \text{2-sided} \\
  P \left( \chi^2(N-1) \leq \frac{h^2(N(N-1))}{\sigma^2_{\text{diff}}(t_{1-\alpha} (N-1))} \right), & \text{1-sided}
\end{cases}
\]

\[
\Pr(\text{half-width} \leq h \mid \text{validity}) = \begin{cases} 
  \left( \frac{1}{1-\alpha} \right) 2 \left[ Q_{N-1} \left( (t_{1-\frac{\alpha}{2}} (N-1)), 0; 0, b_1 \right) - Q_{N-1} (0, 0; 0, b_1) \right], & \text{2-sided} \\
  \left( \frac{1}{1-\alpha} \right) Q_{N-1} \left( (t_{1-\alpha} (N-1)), 0; 0, b_1 \right), & \text{1-sided}
\end{cases}
\]

where

\[
\begin{align*}
\sigma_{\text{diff}} &= \left( \sigma_1^2 + \sigma_2^2 - 2\rho \sigma_1 \sigma_2 \right)^{\frac{3}{2}} \\
b_1 &= \frac{h(N - 1)^{\frac{1}{2}}}{\sigma_{\text{diff}}(t_{1-\frac{\alpha}{2}} (N-1))) N^{-\frac{1}{2}}} \\
c &= \text{number of sides}
\end{align*}
\]

and \( Q(\cdot;\cdot;\cdot) \) is Owen’s Q function, defined in the “Common Notation” section on page 3498.

A “quality” confidence interval is both sufficiently narrow (half-width \( \leq h \)) and valid:

\[
\Pr(\text{quality}) = \Pr(\text{half-width} \leq h \text{ and validity}) = \Pr(\text{half-width} \leq h \mid \text{validity})(1 - \alpha)
\]
Analyses in the TWOSAMPLEFREQ Statement

Overview of the $2 \times 2$ Table

Notation:

<table>
<thead>
<tr>
<th></th>
<th>Group 1</th>
<th></th>
<th>Group 2</th>
<th></th>
</tr>
</thead>
<tbody>

<td>$n_2$</td>
<td>$N$</td>
<td>$m$</td>
</tr>
</tbody>
</table>

$x_1 = \#$ successes in group 1

$x_2 = \#$ successes in group 2

$m = x_1 + x_2 = \text{total \# successes}$

$\hat{p}_1 = \frac{x_1}{n_1}$

$\hat{p}_2 = \frac{x_2}{n_2}$

$\hat{p} = \frac{m}{N} = w_1\hat{p}_1 + w_2\hat{p}_2$

The hypotheses are

$H_0 : p_2 - p_1 = p_0$

$H_1 : \begin{cases} 
    p_2 - p_1 \neq p_0, & \text{2-sided} \\
    p_2 - p_1 > p_0, & \text{upper 1-sided} \\
    p_2 - p_1 < p_0, & \text{lower 1-sided}
\end{cases}$

where $p_0$ is constrained to be 0 for all but the unconditional Pearson chi-square test.

Internal calculations are performed in terms of $p_1$, $p_2$, and $p_0$. An input set consisting of $OR$, $p_1$, and $OR_0$ is transformed as follows:

$p_2 = \frac{(OR)p_1}{1 - p_1 + (OR)p_1}$

$p_{10} = \frac{OR_0p_{10}}{1 - p_{10} + (OR_0)p_{10}}$

$p_{20} = \frac{OR_0p_{10}}{1 - p_{10} + (OR_0)p_{10}}$

$p_0 = p_{20} - p_{10}$
An input set consisting of $RR$, $p_1$, and $RR_0$ is transformed as follows:

\[
\begin{align*}
p_2 &= (RR)p_1 \\
p_{10} &= p_1 \\
p_{20} &= (RR_0)p_{10} \\
p_0 &= p_{20} - p_{10}
\end{align*}
\]

Note that the transformation of either $OR_0$ or $RR_0$ to $p_0$ is not unique. The chosen parameterization fixes the null value $p_{10}$ at the input value of $p_1$.

**Pearson Chi-square Test for Two Proportions (TEST=PCHI)**

The usual Pearson chi-square test is unconditional. The test statistic

\[
z_P = \frac{\hat{p}_2 - \hat{p}_1 - p_0}{\sqrt{\left(\frac{1}{n_1} + \frac{1}{n_2}\right) \left(\frac{p_2 - p_1}{\hat{p}(1 - \hat{p})}\right)}} = \frac{Nw_1w_2}{\hat{p}(1 - \hat{p})} \left(\frac{p_2 - p_1 - p_0}{\hat{p}(1 - \hat{p})}\right)
\]

is assumed to have a null distribution of $N(0, 1)$.

Sample size for the 1-sided cases is given by equation (4) in Fleiss, Tytun, and Ury (1980). One-sided power is computed as suggested by Diegert and Diegert (1981) by inverting the sample size formula. Power for the 2-sided case is computed by adding the lower-sided and upper-sided powers each with $\alpha/2$, and sample size for the 2-sided case is obtained by numerically inverting the power formula. A custom null value $p_0$ for the proportion difference $p_2 - p_1$ is also supported.

\[
power = \begin{cases} 
\Phi \left( \frac{(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\alpha}}{[w_2p_1(1-p_1) + w_1p_2(1-p_2)]^{\frac{1}{2}}} \right), & \text{upper 1-sided} \\
\Phi \left( -\frac{(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\alpha}}{[w_2p_1(1-p_1) + w_1p_2(1-p_2)]^{\frac{1}{2}}} \right), & \text{lower 1-sided} \\
\Phi \left( \frac{(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\alpha}}{[w_2p_1(1-p_1) + w_1p_2(1-p_2)]^{\frac{1}{2}}} \right) + \\
\Phi \left( -\frac{(p_2 - p_1 - p_0)(Nw_1w_2)^{\frac{1}{2}} - z_{1-\alpha}}{[w_2p_1(1-p_1) + w_1p_2(1-p_2)]^{\frac{1}{2}}} \right), & \text{2-sided}
\end{cases}
\]

For the 1-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

\[
N = \left[ z_{1-\alpha} \left\{ (w_1p_1 + w_2p_2)(1 - w_1p_1 - w_2p_2) \right\}^{\frac{1}{2}} + z_{\text{power}} \left\{ w_2p_1(1-p_1) + w_1p_2(1-p_2) \right\}^{\frac{1}{2}} \right]^2 \div w_1w_2(p_2 - p_1 - p_0)^2
\]

For the 2-sided case, the solution for $N$ is obtained by numerically inverting the power equation.
**Likelihood Ratio chi-square Test for Two Proportions (TEST=LRCHI)**

The usual likelihood ratio chi-square test is unconditional. The test statistic

\[ z_{LR} = \left( -1_{\{p_2 < p_1\}} \right) \sqrt{2N \sum_{i=1}^{2} \left[ w_i \hat{p}_i \log \left( \frac{\hat{p}_i}{\hat{p}} \right) + w_i (1 - \hat{p}_i) \log \left( \frac{1 - \hat{p}_i}{1 - \hat{p}} \right) \right] } \]

is assumed to have a null distribution of \( N(0, 1) \) and an alternative distribution of \( N(\delta, 1) \) where

\[ \delta = N^{\frac{1}{2}} \left( -1_{\{p_2 < p_1\}} \right) \sqrt{2 \sum_{i=1}^{2} \left[ w_i p_i \log \left( \frac{p_i}{w_1 p_1 + w_2 p_2} \right) + w_i (1 - p_i) \log \left( \frac{1 - p_i}{1 - (w_1 p_1 + w_2 p_2)} \right) \right] } \]

The approximate power is

\[ \text{power} = \begin{cases} 
\Phi \left( \delta - z_{1-\alpha} \right), & \text{upper 1-sided} \\
\Phi \left( -\delta - z_{1-\alpha} \right), & \text{lower 1-sided} \\
\Phi \left( \delta - z_{1-\frac{\alpha}{2}} \right) + \Phi \left( -\delta - z_{1-\frac{\alpha}{2}} \right), & 2\text{-sided}
\end{cases} \]

For the 1-sided cases, a closed-form inversion of the power equation yield an approximate total sample size

\[ N = \left( \frac{z_{\text{power}} + z_{1-\alpha}}{\delta} \right)^2 \]

For the 2-sided case, the solution for \( N \) is obtained by numerically inverting the power equation.

**Fisher’s Exact Conditional Test for Two Proportions (Test=FISHER)**

Fisher’s exact test is conditional on the observed total number of successes \( m \). Power and sample size computations for the METHOD=WALTERS option are based on a test with similar power properties, the continuity-adjusted arcsine test. The test statistic

\[ z_A = \left( 4N w_1 w_2 \right)^{\frac{1}{2}} \left[ \arcsin \left( \left[ \hat{p}_2 + \frac{1}{2N w_2} (1_{\{\hat{p}_2 < \hat{p}_1\}} - 1_{\{\hat{p}_2 > \hat{p}_1\}}) \right]^{\frac{1}{2}} \right) - \arcsin \left( \left[ \hat{p}_1 + \frac{1}{2N w_1} (1_{\{\hat{p}_1 < \hat{p}_2\}} - 1_{\{\hat{p}_1 > \hat{p}_2\}}) \right]^{\frac{1}{2}} \right) \right] \]

is assumed to have a null distribution of \( N(0, 1) \) and an alternative distribution of \( N(\delta, 1) \) where

\[ \delta = \left( 4N w_1 w_2 \right)^{\frac{1}{2}} \left[ \arcsin \left( \left[ p_2 + \frac{1}{2N w_2} (1_{\{p_2 < p_1\}} - 1_{\{p_2 > p_1\}}) \right]^{\frac{1}{2}} \right) - \arcsin \left( \left[ p_1 + \frac{1}{2N w_1} (1_{\{p_1 < p_2\}} - 1_{\{p_1 > p_2\}}) \right]^{\frac{1}{2}} \right) \right] \]
Chapter 57. The POWER Procedure

The approximate power for the 1-sided balanced case is given by Walters (1979) and is easily extended to the unbalanced and 2-sided cases:

\[
\text{power} = \begin{cases} 
\Phi \left( \delta - z_{1-\alpha} \right), & \text{upper 1-sided} \\
\Phi \left( -\delta - z_{1-\alpha} \right), & \text{lower 1-sided} \\
\Phi \left( \delta - z_{1-\frac{\alpha}{2}} \right) + \Phi \left( -\delta - z_{1-\frac{\alpha}{2}} \right), & \text{2-sided}
\end{cases}
\]

**Analyses in the TWOSAMPLEMEANS Statement**

**Two-sample t Test Assuming Equal Variances (TEST=DIFF)**

The hypotheses for the two-sample t test are

\[
H_0 : \quad \mu_{\text{diff}} = \mu_0 \\
H_1 : \quad \begin{cases} 
\mu_{\text{diff}} \neq \mu_0, & \text{2-sided} \\
\mu_{\text{diff}} > \mu_0, & \text{upper 1-sided} \\
\mu_{\text{diff}} < \mu_0, & \text{lower 1-sided}
\end{cases}
\]

The test assumes normally distributed data and common standard deviation per group, and it requires \(N \geq 3, n_1 \geq 1,\) and \(n_2 \geq 1\). The test statistics are

\[
t = N^{\frac{1}{2}} (w_1 w_2)^{\frac{1}{2}} \left( \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{s_p} \right) \sim t(N - 2, \delta) \\
t^2 \sim F(1, N - 2, \delta^2)
\]

where \(\bar{x}_1\) and \(\bar{x}_2\) are the sample means and \(s_p\) is the pooled standard deviation, and

\[
\delta = N^{\frac{1}{2}} (w_1 w_2)^{\frac{1}{2}} \left( \frac{\mu_{\text{diff}} - \mu_0}{\sigma} \right)
\]

The test is

Reject \(H_0\) if \(\begin{cases} 
t^2 \geq F_{1-\alpha}(1, N - 2), & \text{2-sided} \\
t \geq t_{1-\alpha}(N - 2), & \text{upper 1-sided} \\
t \leq t_{\alpha}(N - 2), & \text{lower 1-sided}
\end{cases}\)

Exact power computations for t tests are given in O’Brien and Muller (1993, section 8.2.1):

\[
\text{power} = \begin{cases} 
P \left( F(1, N - 2, \delta^2) \geq F_{1-\alpha}(1, N - 2) \right), & \text{2-sided} \\
P \left( t(N - 2, \delta) \geq t_{1-\alpha}(N - 2) \right), & \text{upper 1-sided} \\
P \left( t(N - 2, \delta) \leq t_{\alpha}(N - 2) \right), & \text{lower 1-sided}
\end{cases}
\]
Solutions for $N$, $n_1$, $n_2$, $\alpha$, and $\delta$ are obtained by numerically inverting the power equation. Closed-form solutions for other parameters, in terms of $\delta$, are as follows:

\[
\mu_{\text{diff}} = \delta \sigma (N w_1 w_2)^{-\frac{1}{2}} + \mu_0 \\
\mu_1 = \delta \sigma (N w_1 w_2)^{-\frac{1}{2}} + \mu_0 - \mu_2 \\
\mu_2 = \delta \sigma (N w_1 w_2)^{-\frac{1}{2}} + \mu_0 - \mu_1 \\
\sigma = \begin{cases} 
\delta^{-1} (N w_1 w_2)^{\frac{1}{2}} (\mu_{\text{diff}} - \mu_0), & |\delta| > 0 \\
\text{undefined}, & \text{otherwise}
\end{cases} \\
w_1 = \begin{cases} 
\frac{1}{2} \pm \frac{1}{2} \left[ 1 - \frac{4\delta^2 \sigma^2}{N (\mu_{\text{diff}} - \mu_0)^2} \right]^{\frac{1}{2}}, & 0 < |\delta| \leq \frac{1}{2} N^\frac{1}{2} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma} \\
\text{undefined}, & \text{otherwise}
\end{cases} \\
w_2 = \begin{cases} 
\frac{1}{2} \pm \frac{1}{2} \left[ 1 - \frac{4\delta^2 \sigma^2}{N (\mu_{\text{diff}} - \mu_0)^2} \right]^{\frac{1}{2}}, & 0 < |\delta| \leq \frac{1}{2} N^\frac{1}{2} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma} \\
\text{undefined}, & \text{otherwise}
\end{cases}
\]

Finally, here is a derivation of the solution for $w_1$:

Solve the $\delta$ equation for $w_1$ (which requires the quadratic formula). Then determine the range of $\delta$ given $w_1$:

\[
\min_{w_1}(\delta) = \begin{cases} 
0, & \text{when } w_1 = 0 \text{ or } 1, \text{ if } (\mu_{\text{diff}} - \mu_0) \geq 0 \\
\frac{1}{2} N^\frac{1}{2} \frac{(\mu_{\text{diff}} - \mu_0)}{\sigma}, & \text{when } w_1 = \frac{1}{2}, \text{ if } (\mu_{\text{diff}} - \mu_0) < 0
\end{cases}
\]

\[
\max_{w_1}(\delta) = \begin{cases} 
0, & \text{when } w_1 = 0 \text{ or } 1, \text{ if } (\mu_{\text{diff}} - \mu_0) < 0 \\
\frac{1}{2} N^\frac{1}{2} \frac{(\mu_{\text{diff}} - \mu_0)}{\sigma}, & \text{when } w_1 = \frac{1}{2}, \text{ if } (\mu_{\text{diff}} - \mu_0) \geq 0
\end{cases}
\]

This implies

\[
|\delta| \leq \frac{1}{2} N^\frac{1}{2} \frac{|\mu_{\text{diff}} - \mu_0|}{\sigma}
\]

**Two-sample Satterthwaite t Test Assuming Unequal Variances (TEST=DIFF\_SATT)**

The hypotheses for the two-sample Satterthwaite $t$ test are

\[
H_0 : \mu_{\text{diff}} = \mu_0 \\
H_1 : \left\{ \begin{array}{l}
\mu_{\text{diff}} \neq \mu_0, \text{ 2-sided} \\
\mu_{\text{diff}} > \mu_0, \text{ upper 1-sided} \\
\mu_{\text{diff}} < \mu_0, \text{ lower 1-sided}
\end{array} \right.
\]

The test assumes normally distributed data and requires $N \geq 3$, $n_1 \geq 1$, and $n_2 \geq 1$. The test statistics are

\[
t = \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{\sqrt{s^2_1/n_1 + s^2_2/n_2}^{\frac{1}{2}}} = N^\frac{1}{2} \frac{\bar{x}_2 - \bar{x}_1 - \mu_0}{\left[ s^2_1/n_1 + s^2_2/n_2 \right]^{\frac{1}{2}}} \\
F = t^2
\]
where $\bar{x}_1$ and $\bar{x}_2$ are the sample means and $s_1$ and $s_2$ are the sample standard deviations.

As DiSantostefano and Muller (1995, p. 585) state, the test is based on assuming that under $H_0$, $F$ is distributed as $F(1, \nu)$, where $\nu$ is given by Satterthwaite’s approximation (Satterthwaite 1946),

$$
\nu = \left[ \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2} \right]^2 = \frac{\left[ \frac{\sigma_1^2}{n_1} \right]^2}{n_1-1} + \frac{\left[ \frac{\sigma_2^2}{n_2} \right]^2}{n_2-1}
$$

Since $\nu$ is unknown, in practice it must be replaced by an estimate

$$
\hat{\nu} = \left[ \frac{\hat{\sigma}_1^2}{n_1} + \frac{\hat{\sigma}_2^2}{n_2} \right]^2 = \frac{\left[ \frac{\hat{\sigma}_1^2}{n_1} \right]^2}{Nw_1-1} + \frac{\left[ \frac{\hat{\sigma}_2^2}{n_2} \right]^2}{Nw_2-1}
$$

So the test is

$$
\text{Reject } H_0 \quad \text{if} \quad \left\{\begin{array}{ll}
F \geq F_{1-\alpha}(1, \hat{\nu}), & \text{2-sided} \\
 t \geq t_{1-\alpha}(\hat{\nu}), & \text{upper 1-sided} \\
 t \leq t_{\alpha}(\hat{\nu}), & \text{lower 1-sided}
\end{array}\right.
$$

Exact solutions for power for the 2-sided and upper 1-sided cases are given in Moser, Stevens, and Watts (1989). The lower 1-sided case follows easily using symmetry. The equations are as follows:

$$
\text{power} = \left\{\begin{array}{ll}
\int_0^\infty P\left(F(1, N-2, \lambda) > h(u)F_{1-\alpha}(1, v(u))u\right) f(u)du, & \text{2-sided} \\
\int_0^\infty P\left(t(N-2, \lambda^{\frac{1}{2}}) > [h(u)]^{\frac{1}{2}} t_{1-\alpha}(v(u))u\right) f(u)du, & \text{upper 1-sided} \\
\int_0^\infty P\left(t(N-2, \lambda^{\frac{1}{2}}) < [h(u)]^{\frac{1}{2}} t_{\alpha}(v(u))u\right) f(u)du, & \text{lower 1-sided}
\end{array}\right.
$$

where

$$
 h(u) = \frac{\left( \frac{1}{n_1} + \frac{u}{n_2} \right) (n_1 + n_2 - 2)}{(n_1 - 1) + (n_2 - 1) \frac{u^2 \sigma_1^2}{\sigma_2^2}} \left[ \frac{1}{n_1} + \frac{\sigma_2^2}{n_2} \right],
$$

$$
 v(u) = \frac{\left( \frac{1}{n_1} + \frac{u}{n_2} \right)^2}{\frac{1}{n_1^2(n_1-1)} + \frac{u^2}{n_2^2(n_2-1)}},
$$

$$
 \lambda = \frac{(\mu_{\text{diff}} - \mu_0)^2}{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}
$$
The density \( f(u) \) is obtained from the fact that

\[
\frac{u \sigma_1^2}{\sigma_2^2} \sim F(n_2 - 1, n_1 - 1)
\]

**Two-sample Pooled t Test of Mean Ratio with Lognormal Data (TEST=RATIO)**

The lognormal case is handled by re-expressing the analysis equivalently as a normality-based test on the log-transformed data, using properties of the lognormal distribution as discussed in Johnson and Kotz (1970, chapter 14). The approaches in the “Two-sample t Test Assuming Equal Variances (TEST=DIFF)” section on page 3526 then apply.

In contrast to the usual \( t \) test on normal data, the hypotheses with lognormal data are defined in terms of geometric means rather than arithmetic means. The test assumes equal coefficients of variation in the two groups.

The hypotheses for the two-sample \( t \) test with lognormal data are

\[
H_0 : \frac{\gamma_2}{\gamma_1} = \gamma_0
\]

\[
H_1 : \begin{cases} 
\frac{\gamma_2}{\gamma_1} \neq \gamma_0, & \text{2-sided} \\
\frac{\gamma_2}{\gamma_1} > \gamma_0, & \text{upper 1-sided} \\
\frac{\gamma_2}{\gamma_1} < \gamma_0, & \text{lower 1-sided}
\end{cases}
\]

Let \( \mu_1^*, \mu_2^*, \) and \( \sigma^* \) be the (arithmetic) means and common standard deviation of the corresponding normal distributions of the log-transformed data. The hypotheses can be rewritten as follows:

\[
H_0 : \mu_2^* - \mu_1^* = \log(\gamma_0)
\]

\[
H_1 : \begin{cases} 
\mu_2^* - \mu_1^* \neq \log(\gamma_0), & \text{2-sided} \\
\mu_2^* - \mu_1^* > \log(\gamma_0), & \text{upper 1-sided} \\
\mu_2^* - \mu_1^* < \log(\gamma_0), & \text{lower 1-sided}
\end{cases}
\]

where

\[
\mu_1^* = \log \gamma_1 \\
\mu_2^* = \log \gamma_2
\]
The test assumes lognormally distributed data and requires \( N \geq 3 \), \( n_1 \geq 1 \), and \( n_2 \geq 1 \).

The power is

\[
\text{power} = \begin{cases} 
  P \left( F(1, N - 2, \delta^2) \geq F_{1-a}(1, N - 2) \right), & \text{2-sided} \\
  P \left( t(N - 2, \delta) \geq t_{1-a}(N - 2) \right), & \text{upper 1-sided} \\
  P \left( t(N - 2, \delta) \leq t_{a}(N - 2) \right), & \text{lower 1-sided}
\end{cases}
\]

where

\[
\delta = N^{\frac{1}{2}} (w_1 w_2)^{\frac{1}{2}} \left( \frac{\mu^*_2 - \mu^*_1 - \log(\gamma_0)}{\sigma^*} \right)
\]

\[
\sigma^* = \left[ \log(CV^2 + 1) \right]^{\frac{1}{2}}
\]

Additive Equivalence Test for Mean Difference with Normal Data (TEST=EQUIV\_DIFF)

The hypotheses for the equivalence test are

\[
H_0 : \mu_\text{diff} < \theta_L \ or \ \mu_\text{diff} > \theta_U \\
H_1 : \theta_L \leq \mu_\text{diff} \leq \theta_U
\]

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987). The test assumes normally distributed data and requires \( N \geq 3 \), \( n_1 \geq 1 \), and \( n_2 \geq 1 \). Phillips (1990) derives an expression for the exact power assuming a balanced design; the results are easily adapted to an unbalanced design:

\[
\text{power} = Q_{N-2} \left( \left( -t_{1-a}(N - 2), \frac{\mu_\text{diff} - \theta_U}{\sigma N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}}} \right); \\
    0, \frac{(N - 2)^{\frac{1}{2}} (\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}} (t_{1-a}(N - 2))} \right) - \\
Q_{N-2} \left( \left( t_{1-a}(N - 2), \frac{\mu_\text{diff} - \theta_L}{\sigma N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}}} \right); \\
    0, \frac{(N - 2)^{\frac{1}{2}} (\theta_U - \theta_L)}{2\sigma N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}} (t_{1-a}(N - 2))} \right)
\]

where \( Q(\cdot; \cdot; \cdot; \cdot) \) is Owen’s Q function, defined in the “Common Notation” section on page 3498.
Multiplicative Equivalence Test for Mean Ratio with Lognormal Data
(\text{TEST=EQUIV\_RATIO})

The lognormal case is handled by re-expressing the analysis equivalently as a
normality-based test on the log-transformed data, using properties of the lognor-
mal distribution as discussed in Johnson and Kotz (1970, chapter 14). The ap-
proaches in the “Additive Equivalence Test for Mean Difference with Normal Data
(\text{TEST=EQUIV\_DIFF})” section on page 3530 then apply.

In contrast to the additive equivalence test on normal data, the hypotheses with log-
normal data are defined in terms of geometric means rather than arithmetic means.

The hypotheses for the equivalence test are

\[ H_0 : \frac{\gamma_T}{\gamma_R} \leq \theta_L \quad \text{or} \quad \frac{\gamma_T}{\gamma_R} \geq \theta_U \]

\[ H_1 : \theta_L < \frac{\gamma_T}{\gamma_R} < \theta_U \]

where \( 0 < \theta_L < \theta_U \)

The analysis is the two one-sided tests (TOST) procedure of Schuirmann (1987) on
the log-transformed data. The test assumes lognormally distributed data and requires
\( N \geq 3, n_1 \geq 1, \) and \( n_2 \geq 1 \). Diletti, Hauschke, and Steinijans (1991) derive an
expression for the exact power assuming a crossover design; the results are easily
adapted to an unbalanced two-sample design:

\[
\text{power} = Q_{N-2} \left( (t_{1-\alpha/2}(N-2)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_U)}{\sigma^* N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}}}, \right. \\
\left. 0, \frac{(N-2)^{\frac{1}{2}} (\log(\theta_U) - \log(\theta_L))}{2 \sigma^* N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}} (t_{1-\alpha/2}(N-2))} \right) - \\
Q_{N-2} \left( (t_{1-\alpha/2}(N-2)), \frac{\log\left(\frac{\gamma_T}{\gamma_R}\right) - \log(\theta_L)}{\sigma^* N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}}}, \right. \\
\left. 0, \frac{(N-2)^{\frac{1}{2}} (\log(\theta_U) - \log(\theta_L))}{2 \sigma^* N^{-\frac{1}{2}} (w_1 w_2)^{-\frac{1}{2}} (t_{1-\alpha/2}(N-2))} \right)
\]

where

\[ \sigma^* = \left[ \log(CV^2 + 1) \right]^{\frac{1}{2}} \]

is the (assumed common) standard deviation of the normal distribution of the log-
transformed data, and \( Q(\cdot, \cdot; \cdot, \cdot) \) is Owen’s Q function, defined in the “Common
Notation” section on page 3498.
Confidence Interval for Mean Difference (CI=DIFF)

This analysis of precision applies to the standard \( t \)-based confidence interval:

\[
\left[ (\bar{x}_2 - \bar{x}_1) - t_{1-\frac{\alpha}{2}} \frac{s_p}{\sqrt{Nw_1w_2}}, \ (\bar{x}_2 - \bar{x}_1) + t_{1-\frac{\alpha}{2}} \frac{s_p}{\sqrt{Nw_1w_2}} \right],
\]

2-sided

\[
\left[ (\bar{x}_2 - \bar{x}_1) - t_{1-\alpha} (N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, \ \infty \right),
\]

upper 1-sided

\[
\left( -\infty, \ (\bar{x}_2 - \bar{x}_1) + t_{1-\alpha} (N-2) \frac{s_p}{\sqrt{Nw_1w_2}} \right],
\]

lower 1-sided

where \( \bar{x}_1 \) and \( \bar{x}_2 \) are the sample means and \( s_p \) is the pooled standard deviation. The “half-width” is defined as the distance from the point estimate \( \bar{x}_2 - \bar{x}_1 \) to a finite endpoint,

\[
\text{half-width} = \begin{cases} 
  t_{1-\frac{\alpha}{2}} \frac{(N-2)}{\sqrt{Nw_1w_2}} s_p, & \text{2-sided} \\
  t_{1-\alpha} (N-2) \frac{s_p}{\sqrt{Nw_1w_2}}, & \text{1-sided}
\end{cases}
\]

A “valid” conference interval captures the true mean. The exact probability of obtaining at most the target confidence interval half-width \( h \), unconditional or conditional on validity, is given by Beal (1989):

\[
\text{Pr}(\text{half-width} \leq h) = \begin{cases} 
  P \left( \chi^2(N-2) \leq \frac{h^2 N(N-2)(w_1w_2)}{\sigma^2(t_{1-\frac{\alpha}{2}}(N-2))} \right), & \text{2-sided} \\
  P \left( \chi^2(N-2) \leq \frac{h^2 N(N-2)(w_1w_2)}{\sigma^2(t_{1-\alpha}(N-2))} \right), & \text{1-sided}
\end{cases}
\]

\[
\text{Pr}(\text{half-width} \leq h \mid \text{validity}) = \begin{cases} 
  \left( \frac{1}{1-\alpha} \right) 2 \left[ Q_{N-2} ((t_{1-\frac{\alpha}{2}}(N-2)), 0; 0, b_2) - Q_{N-2} (0, 0, 0, b_2) \right], & \text{2-sided} \\
  \left( \frac{1}{1-\alpha} \right) Q_{N-2} ((t_{1-\alpha}(N-2)), 0; 0, b_2), & \text{1-sided}
\end{cases}
\]

where

\[
b_2 = \frac{h(N-2)^{\frac{1}{2}}}{\sigma(t_{1-\frac{\alpha}{2}}(N-2))N^{-\frac{1}{2}}(w_1w_2)^{-\frac{1}{2}}}
\]

\( c \) = number of sides

and \( Q(\cdot; \cdot; \cdot; \cdot) \) is Owen’s Q function, defined in the “Common Notation” section on page 3498.

A “quality” confidence interval is both sufficiently narrow (half-width \( \leq h \)) and valid:

\[
\text{Pr(quality)} = \text{Pr}(\text{half-width} \leq h \text{ and validity}) = \text{Pr}(\text{half-width} \leq h \mid \text{validity})(1 - \alpha)
\]
**Analyses in the TWOSAMPLESURVIVAL Statement**

**Rank Tests for Two Survival Curves (TEST=LOGRANK, TEST=GEHAN, TEST=TARONEWARE)**

Define the following notation:

\[
\begin{align*}
X_j(i) &= i\text{th input time point on survival curve for group } j \\
S_j(i) &= \text{input survivor function value corresponding to } X_j(i) \\
h_j(t) &= \text{hazard rate for group } j \text{ at time } t \\
\Psi_j(t) &= \text{loss hazard rate for group } j \text{ at time } t \\
\lambda_j &= \text{exponential hazard rate for group } j \\
R &= \text{hazard ratio of group 2 to group 1} \equiv \text{(assumed constant) value of } \frac{h_2(t)}{h_1(t)} \\
m_j &= \text{median survival time for group } j \\
b &= \text{number of subintervals per time unit} \\
T &= \text{accrual time} \\
\tau &= \text{post-accrual follow-up time} \\
L_j &= \text{exponential loss rate for group } j \\
XL_j &= \text{input time point on loss curve for group } j \\
SL_j &= \text{input survivor function value corresponding to } XL_j \\
mL_j &= \text{median survival time for group } j \\
r_i &= \text{rank for } i\text{th time point}
\end{align*}
\]

Each survival curve can be specified in one of several ways.

- **For exponential curves:**
  - a single point \((X_j(1), S_j(1))\) on the curve
  - median survival time
  - hazard rate
  - hazard ratio (for curve 2, with respect to curve 1)

- **For piecewise linear curves with proportional hazards:**
  - a set of points \(\{(X_1(1), S_1(1)), (X_1(2), S_1(2)), \ldots\}\) (for curve 1)
  - hazard ratio (for curve 2, with respect to curve 1)

- **For arbitrary piecewise linear curves:**
  - a set of points \(\{(X_j(1), S_j(1)), (X_j(2), S_j(2)), \ldots\}\)

A total of \(M\) evenly spaced time points \(\{t_0 = 0, t_1, t_2, \ldots, t_M = T + \tau\}\) are used in calculations, where

\[
M = \text{floor } ((T + \tau)b)
\]
The hazard function is calculated for each survival curve at each time point. For an exponential curve, the (constant) hazard is given by one of the following, depending on the input parameterization:

\[ h_j(t) = \left\{ \begin{array}{l}
\frac{\lambda_j}{\lambda_1 R} \\
\frac{m_j}{-\log(S_j(1))} \\
\frac{X_j(1)}{-\log(S_1(1)) R}
\end{array} \right. \]

For a piecewise linear curve, define the following additional notation:

\[ t_i^- = \text{largest input time } X \text{ such that } X \leq t_i \]
\[ t_i^+ = \text{smallest input time } X \text{ such that } X > t_i \]

The hazard is computed using linear interpolation as follows:

\[ h_j(t_i) = \frac{S_j(t_i^-) - S_j(t_i^+)}{[S_j(t_i^+) - S_j(t_i^-)] [t_i - t_i^-] + S_j(t_i^-) [t_i^+ - t_i^-]} \]

With proportional hazards, the hazard rate of group 2’s curve in terms of the hazard rate of group 1’s curve is

\[ h_2(t) = h_1(t) R \]

Hazard function values \( \{\Psi_j(t_i)\} \) for the loss curves are computed in an analogous way from \( \{L_j, XL_j, SL_j, mL_j\} \).

The expected number at risk \( N_j(i) \) at time \( i \) in group \( j \) is calculated for each group and time points \( 0 \) through \( M - 1 \), as follows:

\[ N_j(0) = N_{wj} \]
\[ N_j(i + 1) = N_j(i) \left[ 1 - h_j(t_i) \left( \frac{1}{b} \right) - \Psi_j(t_i) \left( \frac{1}{b} \right) - \left( \frac{1}{b(T + \tau - t_i)} \right) 1\{t_i > \tau\} \right] \]

Define \( \theta_i \) as the ratio of hazards and \( \phi_i \) as the ratio of expected numbers at risk for time \( t_i \):

\[ \theta_i = \frac{h_2(t_i)}{h_1(t_i)} \]
\[ \phi_i = \frac{N_2(i)}{N_1(i)} \]
The expected number of deaths in each subinterval is calculated as follows:

\[ D_i = [h_1(t_i)N_1(i) + h_2(t_i)N_2(i)] \left( \frac{1}{b_1} \right) \]

The rank values are calculated as follows according to which test statistic is used:

\[ r_i = \begin{cases} 
1, & \text{log-rank} \\
N_1(i) + N_2(i), & \text{Gehan} \\
\sqrt{N_1(i) + N_2(i)}, & \text{Tarone-Ware}
\end{cases} \]

The distribution of the test statistic is approximated by \( N(E, 1) \) where

\[ E = \frac{\sum_{i=0}^{M-1} D_i r_i \left[ \frac{\phi_i \theta_i}{1+\phi_i \theta_i} - \frac{\phi_i}{1+\phi_i} \right]}{\sqrt{\sum_{i=0}^{M-1} D_i r_i^2 \frac{\phi_i}{(1+\phi_i)^2}}} \]

Note that \( N^{\frac{1}{2}} \) can be factored out of the mean \( E \), and so it can be expressed equivalently as

\[ E = N^{\frac{1}{2}} E^* = N^{\frac{1}{2}} \left[ \frac{\sum_{i=0}^{M-1} D_i r_i^* \left[ \frac{\phi_i \theta_i}{1+\phi_i \theta_i} - \frac{\phi_i}{1+\phi_i} \right]}{\sqrt{\sum_{i=0}^{M-1} D_i r_i^*^2 \frac{\phi_i}{(1+\phi_i)^2}}} \right] \]

where \( E^* \) is free of \( N \) and

\[ D_i^* = [h_1(t_i)N_1^*(i) + h_2(t_i)N_2^*(i)] \left( \frac{1}{b} \right) \]

\[ r_i^* = \begin{cases} 
1, & \text{log-rank} \\
N_1^*(i) + N_2^*(i), & \text{Gehan} \\
\sqrt{N_1^*(i) + N_2^*(i)}, & \text{Tarone-Ware}
\end{cases} \]

\[ N_j^*(0) = w_j \]

\[ N_j^*(i + 1) = N_j^*(i) \left[ 1 - h_j(t_i) \left( \frac{1}{b} \right) - \Psi_j(t_i) \left( \frac{1}{b} \right) - \left( \frac{1}{b(T + \tau - t_i)} \right) \right]_{\{t_i > \tau\}} \]

The approximate power is

\[ \text{power} = \begin{cases} 
\Phi \left( -N^{\frac{1}{2}} E^* - z_{1-\alpha} \right), & \text{upper 1-sided} \\
\Phi \left( N^{\frac{1}{2}} E^* - z_{1-\alpha} \right), & \text{lower 1-sided} \\
\Phi \left( -N^{\frac{1}{2}} E^* - z_{1-\alpha} \right) + \Phi \left( N^{\frac{1}{2}} E^* - z_{1-\alpha/2} \right), & \text{2-sided}
\end{cases} \]

Note that the upper and lower 1-sided cases are expressed differently than in other analyses. This is because \( E^* > 0 \) corresponds to a higher survival curve in group
and thus, by the convention used in PROC power for 2-group analyses, the lower side.

For the 1-sided cases, a closed-form inversion of the power equation yields an approximate total sample size

\[ N = \left( \frac{z_{\text{power}} + z_{1-\alpha}}{E^*} \right)^2 \]

For the 2-sided case, the solution for \( N \) is obtained by numerically inverting the power equation.

**Examples**

**Example 57.1. One-Way ANOVA**

This example deals with the same situation as in Example 34.1 on page 1951 of Chapter 34, “The GLMPOWER Procedure.”

Hocking (1985, p. 109) describes a study of the effectiveness of electrolytes in reducing lactic acid buildup for long-distance runners. You are planning a similar study in which you will allocate five different fluids to runners on a 10-mile course and measure lactic acid buildup immediately after the race. The fluids consist of water and two commercial electrolyte drinks, EZDure and LactoZap, each prepared at two concentrations, low (EZD1 and LZ1) and high (EZD2 and LZ2).

You conjecture that the standard deviation of lactic acid measurements given any particular fluid is about 3.75, and that the expected lactic acid values will correspond roughly to those in Table 57.27. You are least familiar with the LZ1 drink and hence decide to consider a range of reasonable values for that mean.

**Table 57.27.** Mean Lactic Acid Buildup by Fluid

<table>
<thead>
<tr>
<th>Fluid</th>
<th>EZD1</th>
<th>EZD2</th>
<th>LZ1</th>
<th>LZ2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water</td>
<td>35.6</td>
<td>33.7</td>
<td>30.2</td>
<td>29 or 28</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>25.9</td>
</tr>
</tbody>
</table>

You are interested in four different comparisons, shown in Table 57.28 with appropriate contrast coefficients.

**Table 57.28.** Planned Comparisons

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Contrast Coefficients</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water versus electrolytes</td>
<td>4 -1 -1 -1 -1</td>
</tr>
<tr>
<td>EZD versus LZ</td>
<td>0 1 1 -1 -1</td>
</tr>
<tr>
<td>EZD1 versus EZD2</td>
<td>0 1 -1 0 0</td>
</tr>
<tr>
<td>LZ1 versus LZ2</td>
<td>0 0 0 1 -1</td>
</tr>
</tbody>
</table>

For each of these contrasts you want to determine the sample size required to achieve a power of 0.9 for detecting an effect with magnitude in accord with Table 57.27. You are not yet attempting to choose a single sample size for the study, but rather checking the range of sample sizes needed for individual contrasts. You plan to test
each contrast at $\alpha = 0.025$. In the interests of reducing costs, you will provide
twice as many runners with water as with any of the electrolytes; in other words, you
will use a sample size weighting scheme of 2:1:1:1:1. Use the ONewayANOVA
statement in the POWER procedure to compute the sample sizes. The statements
required to perform this analysis are as follows:

```plaintext
proc power;
   onewayanova
      groupmeans = 35.6 | 33.7 | 30.2 | 29  28 | 25.9
      stddev = 3.75
      groupweights = (2 1 1 1 1)
      alpha = 0.025
      ntotal = .
      power = 0.9
      contrast = (4 -1 -1 -1 -1) (0  1  1 -1 -1)
                 (0  1 -1  0  0) (0  0  0  1 -1);
run;
```

The NTOTAL= option with a missing value (.) indicates total sample size as the re-
sult parameter. The GROUPMEANS= option with values from Table 57.27 specifies
your conjectures for the means. With only one mean varying (the LZ1 mean), the
“crossed” notation is simpler, showing scenarios for each group mean separated by
a vertical bar (|). See the “Specifying Value Lists in Analysis Statements” section
on page 3490 for more details on crossed and matched notations for grouped val-
ues. The contrasts in Table 57.28 are specified with the CONTRAST option, using
the “matched” notation with each contrast enclosed in parentheses. The STDDEV=,
ALPHA=, and POWER= options specify the error standard deviation, significance
level, and power. The GROUPWEIGHTS= option specifies the weighting schemes.
Default values for the NULL= and SIDES= options specify a 2-sided $t$ test of the
contrast equal to 0. See Output 57.1.1 for the output.

<tr>
<td>8</td>
<td>0 0 0 1 -1</td>
<td>35.6 33.7 30.2 28 25.9</td>
<td>0.902</td>
<td>480</td>
</tr>
</tbody>
</table>

The sample sizes in Output 57.1.1 range from 24 for the comparison of water versus electrolytes to 480 for the comparison of LZ1 versus LZ2, both assuming the smaller LZ1 mean. The sample size for the latter comparison is relatively large because the small mean difference of $28 - 25.9 = 2.1$ is hard to detect.

The Nominal Power of 0.9 in the Fixed Scenario Elements table in Output 57.1.1 represents the input target power, and the Actual Power column in the Computed N Total table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting. Note that all of the sample sizes are rounded up to multiples of 6 to preserve integer group sizes (since the group weights add up to 6). You can use the NFRACTIONAL option in the ONEWAYANOVA statement to compute raw fractional sample sizes.

Suppose you want to plot the required sample size for the range of power values from 0.5 to 0.95. First, define the analysis by specifying the same statements as before, but add the PLOTONLY option to the PROC POWER statement to disable the nongraphical results. Next, specify the PLOT statement with X=POWER to request a plot with power on the x-axis. (The result parameter, here sample size, is always plotted on the other axis.) Use the MIN= and MAX= options in the PLOT statement to specify the power range.

```
proc power plotonly;
  onewayanova
    groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
    stddev = 3.75
    groupweights = (2 1 1 1 1)
```
Example 57.1. One-Way ANOVA

\[
\begin{align*}
\text{alpha} &= 0.025 \\
\text{ntotal} &= . \\
\text{power} &= 0.9 \\
\text{contrast} &= (4 -1 -1 -1 -1) (0 1 1 -1 -1) \\
&\quad (0 1 -1 0 0) (0 0 0 1 -1); \\
\text{plot} x=\text{power} \text{ min=.5 max=.95}; \\
\text{run}; \\
\end{align*}
\]

See Output 57.1.2 for the resulting plot.

**Output 57.1.2.** Plot of Sample Size versus Power for One-Way ANOVA Contrasts

In Output 57.1.2, the line style identifies the contrast, and the plotting symbol identifies the group means scenario. The plot shows that the required sample size is highest for the (0 0 0 1 -1) contrast, corresponding to the test of LZ1 versus LZ2 that was previously found to require the most resources, in either cell means scenario.

Note that some of the plotted points in Output 57.1.2 are unevenly spaced. This is because the plotted points are the rounded sample size results at their corresponding actual power levels. The range specified with the MIN= and MAX= values in the PLOT statement correspond to nominal power levels. In some cases, actual power is substantially higher than nominal power. To obtain plots with evenly spaced points (but with fractional sample sizes at the computed points), you can use the NFRACTIONAL option in the analysis statement preceding the PLOT statement.

Finally, suppose you want to plot the power for the range of sample sizes you will likely consider for the study (the range of 24 to 480 that achieves 0.9 power for different comparisons). In the ONEWAYANOVA statement, identify power as the result
(POWER=.), and specify NTOTAL=24. The following statements produce the plot:

```
proc power plotonly;
onewayanova
   groupmeans = 35.6 | 33.7 | 30.2 | 29 28 | 25.9
   stddev = 3.75
   groupweights = (2 1 1 1 1)
   alpha = 0.025
   ntotal = 24
   power = .
   contrast = (4 -1 -1 -1 -1) (0 1 1 -1 -1)
    (0 1 -1 0 0) (0 0 0 1 -1);
   plot x=n min=24 max=480;
run;
```

The X=N option in the PLOT statement requests a plot with sample size on the x-axis. Note that the value specified with the NTOTAL=24 option is not used. It is overridden in the plot by the MIN= and MAX= options in the PLOT statement, and the PLOTONLY option in the PROC POWER statement disables non-graphical results. But the NTOTAL= option (along with a value) is still needed in the ONewayANOVA statement as a placeholder, to identify the desired parameterization for sample size.

See Output 57.1.3 for the plot.

**Output 57.1.3.** Plot of Power versus Sample Size for One-Way ANOVA Contrasts
Although Output 57.1.2 and Output 57.1.3 surface essentially the same computations for practical power ranges, they each provide a different quick visual assessment. Output 57.1.2 reveals the range of required sample sizes for powers of interest, and Output 57.1.3 reveals the range of achieved powers for sample sizes of interest.

Example 57.2. The Sawtooth Power Function in Proportion Analyses

For many common statistical analyses, the power curve is monotonically increasing: the more samples you take, the more power you achieve. However, in statistical analyses of discrete data, such as tests of proportions, the power curve is often non-monotonic. A small increase in sample size can result in a decrease in power, a decrease that is sometimes substantial. The explanation is that the actual significance level (in other words, the achieved Type 1 error rate) for discrete tests strays below the target level and varies with sample size. The power loss from a decrease in the Type 1 error rate may outweigh the power gain from an increase in sample size. The example discussed in this section demonstrates this “sawtooth” phenomenon. For additional discussion on the topic, refer to Chernick and Liu (2002).

Suppose you have a new scheduling system for an airline, and you want to determine how many flights you must observe to have at least an 80% chance of establishing an improvement in the proportion of late arrivals on a specific travel route. You will use a 1-sided exact binomial proportion test with a null proportion of 30%, the frequency of late arrivals under the previous scheduling system, and a nominal significance level of $\alpha = 0.05$. Well-supported predictions estimate the new late arrival rate to be about 20%, and you will base your sample size determination on this assumption.

The POWER procedure does not currently compute exact sample size directly for the exact binomial test. But you can get an initial estimate by computing the approximate sample size required for a $z$ test. Use the ONESAMPLEFREQ statement in the POWER procedure with TEST=Z and METHOD=NORMAL to compute the approximate sample size to achieve a power of 0.8 using the $z$ test. The following statements perform the analysis:

```plaintext
proc power;
   onesamplefreq test=z method=normal
      sides = 1
      alpha = 0.05
      nullproportion = 0.3
      proportion = 0.2
      ntotal = .
      power = 0.8;
run;
```

The NTOTAL= option with a missing value (.) indicates sample size as the result parameter. The SIDES=1 option specifies a 1-sided test. The ALPHA=, NULLPROPORTION=, and POWER= options specify the significance level of 0.05, null value of 0.3, and target power of 0.8. The PROPORTION= option specifies your conjecture of 0.3 for the true proportion.
Output 57.2.1. Approximate Sample Size for z Test of a Proportion

The results, shown in Output 57.2.1, indicate that you need to observe about $N=119$ flights to have an 80% chance of rejecting the hypothesis of a late arrival proportion of 30% or higher, if the true proportion is 20%, using the $z$ test. A similar analysis (Output 57.2.2) reveals an approximate sample size of $N=129$ for the $z$ test with continuity correction, which performed using TEST=ADJZ:

```plaintext
proc power;
   onesamplefreq test=adjz method=normal
      sides    = 1
      alpha    = 0.05
      nullproportion = 0.3
      proportion  = 0.2
      ntotal     = .
      power      = 0.8;
run;
```
**Output 57.2.2.** Approximate Sample Size for z Test with Continuity Correction

<table>
<thead>
<tr>
<th>The POWER Procedure</th>
<th>Z Test for Binomial Proportion with Continuity Adjustment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed Scenario Elements</td>
<td></td>

</tr>
<tr>
<td>0.801 129</td>
<td></td>
</tr>
</tbody>
</table>

Based on the approximate sample size results, you decide to explore the power of the exact binomial test for sample sizes between 110 and 140. The following statements produce the plot:

```plaintext
proc power plotonly;
  onesamplefreq test=exact
    sides = 1
    alpha = 0.05
    nullproportion = 0.3
    proportion = 0.2
    ntotal = 119
    power = .;
    plot x=n min=110 max=140 step=1
    yopts=(ref=.8) xopts=(ref=119 129);
run;
```

The TEST=EXACT option in the ONESAMPLEFREQ statement specifies the exact binomial test, and the missing value (.) for the POWER= option indicates power as the result parameter. The PLOTONLY option in the PROC POWER statement disables nongraphical output. The PLOT statement with X=N requests a plot with sample size on the x-axis. The MIN= and MAX= options in the PLOT statement specify the sample size range. The YOPTS=(REF=) and XOPTS=(REF=) options add reference lines to highlight the approximate sample size results. The STEP=1 option produces a point at each integer sample size. The sample size value specified with the NTOTAL= option in the ONESAMPLEFREQ statement is overridden by the MIN= and MAX= options in the PLOT statement. **Output 57.2.3** shows the plot.
Output 57.2.3.  Plot of Power versus Sample Size for Exact Binomial Test

Note the sawtooth pattern in Output 57.2.3. Although the power surpasses the target level of 0.8 at \( N=119 \), it decreases to 0.79 with \( N=120 \) and further to 0.76 with \( N=122 \) before rising again to 0.81 with \( N=123 \). Not until \( N=130 \) does the power stay above the 0.8 target. Thus, a more conservative sample size recommendation of 130 might be appropriate, depending on the precise goals of the sample size determination.

In addition to considering alternative sample sizes, you may also want to assess the sensitivity of the power to inaccuracies in assumptions about the true proportion. The following statements produce a plot including true proportion values of 0.18 and 0.22. They are identical to the previous statements except for the additional true proportion values specified with the PROPORTION= option in the ONESAMPLEFREQ statement.

```sas
proc power plotonly;
    onessamplefreq test=exact
        sides = 1
        alpha = 0.05
        nullproportion = 0.3
        proportion = 0.18 0.2 0.22
        ntotal = 119
        power = .;
    plot x=n min=110 max=140 step=1
        yopts=(ref=.8) xopts=(ref=119 129);
run;
```

Output 57.2.4 shows the plot.
Example 57.2. The Sawtooth Power Function in Proportion Analyses

Output 57.2.4. Plot for Assessing Sensitivity to True Proportion Value

The plot reveals a dramatic sensitivity to the true proportion value. For $N=119$, the power is about 0.92 if the true proportion is 0.22, and as low as 0.62 if the proportion is 0.18. Note also that the power jumps occur at the same sample sizes in all three curves; the curves are only shifted and stretched vertically. This is because spikes and valleys in power curves are invariant to the true proportion value; they are due to changes in the critical value of the test.

A closer look at some ancillary output from the analysis sheds light on this property of the sawtooth pattern. You can add an ODS OUTPUT statement to save the plot content corresponding to Output 57.2.3 to a data set:

```
proc power plotonly;
   ods output plotcontent=PlotData;
   onesamplefreq test=exact
      sides   = 1
      alpha   = 0.05
      nullproportion = 0.3
      proportion = 0.2
      ntotal   = 119
      power    = .;
   plot x=n min=110 max=140 step=1
      yopts=(ref=.8) xopts=(ref=119 129);
run;
```

The `PlotData` data set contains parameter values for each point in the plot. The parameters including underlying characteristics of
Chapter 57. The POWER Procedure

The following statements print the critical value and actual significance level along with sample size and power.

```proc print data=PlotData;
  var NTotal LowerCritVal Alpha Power;
run;
```

Output 57.2.5 shows the plot data.

**Output 57.2.5.** Numerical Content of Plot

</table>

Note that whenever the critical value changes, the actual $\alpha$ jumps up to a value close to the nominal $\alpha=0.05$, and the power also jumps up. Then while the critical value stays constant, the actual $\alpha$ and power slowly decrease. The critical value is independent of the true proportion value. So, you can achieve a locally maximal power by choosing a sample size corresponding to a spike on the sawtooth curve, and this choice is locally optimal regardless of the unknown value of the true proportion. Locally optimal sample sizes in this case include 115, 119, 123, 127, 130, and 134.

As a point of interest, the power does not always jump sharply and decrease gradually. The shape of the sawtooth depends on the direction of the test and
the location of the null proportion relative to 0.5. For example, if the di-
rection of the hypothesis in this example is reversed (by switching true and
null proportion values) so that the rejection region is in the upper tail, then
the power curve exhibits sharp decreases and gradual increases. The follow-
ing statements are similar to those producing the plot in Output 57.2.3 but with
values of the PROPORTION= and NULLPROPORTION= options switched.

```
proc power plotonly;
   onesamplefreq test=exact
       sides      = 1
       alpha      = 0.05
       nullproportion = 0.2
       proportion  = 0.3
       ntotal     = 119
       power      = .;
   plot x=n min=110 max=140 step=1;
run;
```

The resulting plot is shown in Output 57.2.6.

**Output 57.2.6.** Plot of Power versus Sample Size for Another 1-Sided Test

Finally, 2-sided tests can lead to even more irregular power curve shapes, since
changes in lower and upper critical values affect the power in different ways. The
following statements produce a plot of power versus sample size for the scenario of
a 2-sided test with high alpha and a true proportion close to the null value.
Chapter 57. The POWER Procedure

```
proc power plotonly;
  onesamplefreq test=exact
    sides = 2
    alpha = 0.2
    nullproportion = 0.1
    proportion = 0.09
    ntotal = 10
    power = .;
  plot x=n min=2 max=100 step=1;
run;
```

The resulting plot is shown in Output 57.2.7.

**Output 57.2.7.** Plot of Power versus Sample Size for a 2-Sided Test

Due to the irregular shapes of power curves for proportion tests, the question “Which sample size should I use?” is often insufficient. A sample size solution produced directly in PROC POWER reveals the smallest possible sample size to achieve your target power. But as the Examples in this section demonstrate, it is helpful to consult graphs for answers to questions such as the following:

- Which sample size will guarantee that all higher sample sizes also achieve my target power?
- Given a candidate sample size, can I increase it slightly to achieve locally maximal power, or perhaps even decrease it and get higher power?
Example 57.3. Simple AB/BA Crossover Designs

Crossover trials are experiments in which each subject is given a sequence of different treatments. They are especially common in clinical trials for medical studies. The reduction in variability from taking multiple measurements on a subject allows for more precise treatment comparisons. The simplest such design is the AB/BA crossover, in which each subject receives each of two treatments in a randomized order.

Under certain simplifying assumptions, you can test the treatment difference in an AB/BA crossover trial using either a paired or two-sample $t$ test (or equivalence test, depending on the hypothesis). This example will demonstrate when and how you can use the PAIREDMEANS statement in PROC POWER to perform power analyses for AB/BA crossover designs.

Senn (1993, Chapter 3) discusses a study comparing the effects of two bronchodilator medications in treatment of asthma, using an AB/BA crossover design. Suppose you want to plan a similar study comparing two new medications, “Xilodol” and “Brantium.” Half of the patients would be assigned to sequence AB, getting a dose of Xilodol in the first treatment period, a wash-out period of one week, and then a dose of Brantium in the second treatment period. The other half would be assigned to sequence BA, following the same schedule but with the drugs reversed. In each treatment period you would administer the drugs in the morning and then measure peak expiratory flow (PEF) at the end of the day, with higher PEF representing better lung function.

You conjecture that the mean and standard deviation of PEF are about $\mu_A = 310$ and $\sigma_A = 40$ for Xilodol and $\mu_B = 330$ and $\sigma_B = 55$ for Brantium, and that each pair of measurements on the same subject will have a correlation of about 0.3. You want to compute the power of both 1-sided and 2-sided tests of mean difference, with a significance level of $\alpha = 0.01$, for a sample size of 100 patients and also plot the power for a range of 50 to 200 patients. Note that the allocation ratio of patients to the two sequences is irrelevant in this analysis.

The choice of statistical test depends on which assumptions are reasonable. One possibility is a $t$ test. A paired or two-sample $t$ test is valid when there is no carryover effect and no interactions between patients, treatments, and periods. See Senn (1993, Chapter 3) for more details. The choice between a paired or a two-sample test depends on what you assume about the period effect. If you assume no period effect, then a paired $t$ test is the appropriate analysis for the design, with the first member of each pair being the Xilodol measurement (regardless of which sequence the patient belongs to). Otherwise the two-sample $t$ test approach is called for, since this analysis adjusts for the period effect using an extra degree of freedom.

Suppose you assume no period effect. Then you can use the PAIREDMEANS statement in PROC POWER with the TEST=DIFF option to perform a sample size analysis for the paired $t$ test. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Specify the conjectured means and standard deviations for each drug using the PAIREDMEANS= and PAIREDSTDDEVS= options and the correlation using the CORR= option. Specify both 1- and 2-sided
tests using the SIDES= option, the significance level using the ALPHA= option, and
the sample size (in terms of number of pairs) using the NPAIRS= option. Generate
a plot of power versus sample size by specifying the PLOT statement with X=N to
request a plot with sample size on the x-axis. (The result parameter, here power, is
always plotted on the other axis.) Use the MIN= and MAX= options in the PLOT
statement to specify the sample size range (as numbers of pairs).

The following statements perform the sample size analysis.

```plaintext
proc power;
  pairedmeans test=diff
    pairedmeans  = (330 310)
    pairedstddevs = (40 55)
    corr          = 0.3
    sides         = 1 2
    alpha         = 0.01
    npairs        = 100
    power         = .;
  plot x=n min=50 max=200;
run;
```

Default values for the NULLDIFF= and DIST= options specify a null mean differ-
ence of 0 and the assumption of normally distributed data. The output is shown in
Output 57.3.1 and Output 57.3.2.

Example 57.3. Simple AB/BA Crossover Designs

Output 57.3.2.  Plot of Power versus Sample Size for Paired t Analysis of Crossover Design

The Computed Power table in Output 57.3.1 shows that the power with 100 patients is about 0.8 for the 2-sided test and 0.87 for the 1-sided test with the alternative of larger Brantium mean. In Output 57.3.2, the line style identifies the number of sides of the test. The plotting symbols identify locations of actual computed powers; the curves are linear interpolations of these points. The plot demonstrates how much higher the power is for the 1-sided test than the 2-sided test for the range of sample sizes.

Suppose now that instead of detecting a difference between Xilodol and Brantium, you want to establish that they are similar, in particular, that the absolute mean PEF difference is at most 35. You might consider this goal if, for example, one of the drugs has fewer side effects and if a difference of no more than 35 is considered clinically small. Instead of a standard \( t \) test, you would conduct an equivalence test of the treatment mean difference for the two drugs. You would test the hypothesis that the true difference is less than -35 or more than 35 against the alternative that the mean difference is between -35 and 35, using an additive model and a two one-sided tests (“TOST”) analysis.

Assuming no period effect, you can use the PAIREDMEANS statement with the TEST=EQUIV_DIFF option to perform a sample size analysis for the paired equivalence test. Indicate power as the result parameter by specifying the POWER= option with a missing value (.). Use the LOWER= and UPPER= options to specify the equivalence bounds of -35 and 35. Use the PAIREDMEANS=, PAIREDSSTDDEV=, CORR=, and ALPHA= options in the same way as in the \( t \) test at the beginning of this example to specify the remaining parameters.
The following statements perform the sample size analysis.

```sas
proc power;
   pairedmeans test=equiv_add
   lower = -35
   upper = 35
   pairedmeans = (330 310)
   pairedstddevs = (40 55)
   corr = 0.3
   alpha = 0.01
   npairs = 100
   power = .;
run;
```

The default option DIST=NORMAL specifies an assumption of normally distributed data. The output is shown in Output 57.3.3.

The power for the paired equivalence test with 100 patients is about 0.6.

Example 57.4. Noninferiority Test with Lognormal Data

The typical goal in noninferiority testing is to conclude that a new treatment or process or product is not appreciably worse than some standard. This is accomplished by convincingly rejecting a 1-sided null hypothesis that the new treatment is appreciably worse than the standard. When designing such studies, investigators must define precisely what constitutes “appreciably worse.”
You can use the POWER procedure for sample size analyses for a variety of noninferiority tests, by specifying custom, 1-sided null hypotheses for common tests. This example illustrates the strategy (often called Blackwelder’s scheme, Blackwelder 1982) by comparing the means of two independent lognormal samples. The logic applies to one-sample, two-sample, and paired-sample problems involving normally distributed measures and proportions.

Suppose you are designing a study hoping to show that a new (less expensive) manufacturing process does not produce appreciably more pollution than the current process. Quantifying “appreciably worse” as 10%, you seek to show that the mean pollutant level from the new process is less than 110% of that from the current process. In standard hypothesis testing notation, you seek to reject

\[ H_0: \frac{\mu_{\text{new}}}{\mu_{\text{current}}} \geq 1.10 \]

in favor of

\[ H_A: \frac{\mu_{\text{new}}}{\mu_{\text{current}}} \lt 1.10 \]

This is described graphically in Figure 57.8. Mean ratios below 100% are better levels for the new process; a ratio of 100% indicates absolute equivalence; ratios of 100–110% are “tolerably” worse; and ratios exceeding 110% are appreciably worse.

Measurements of the pollutant level will be taken using laboratory models of the two processes and will be treated as independent lognormal observations with a coefficient of variation \((\sigma/\mu)\) between 0.5 and 0.6 for both processes. You will end up with 300 measurements for the current process and 180 for the new one. It is important to
avoid a Type 1 error here, so you set the Type 1 error rate to 0.01. Your theoretical
d work suggests that the new process will actually reduce the pollutant by about 10%
to 90% of current), but you need to compute and graph the power of the study if the
new levels are actually between 70% and 120% of current levels.

Implement the sample size analysis using the TWOSAMPLEMEANS statement in
PROC POWER with the TEST=RATIO option. Indicate power as the result param-
eter by specifying the POWER= option with a missing value (.). Specify a series
of scenarios for the mean ratio between 0.7 and 1.2 using the MEANRATIO= op-
tion. Use the NULLRATIO= option to specify the null mean ratio of 1.10. Specify
SIDES=L to indicate a 1-sided test with the alternative hypothesis stating that the
mean ratio is lower than the null value. Specify the significance level, scenarios for
the coefficient of variation, and the group sample sizes using the ALPHA=, CV=,
and GROUPNS= options. Generate a plot of power versus mean ratio by specifying
the PLOT statement with X=EFFECT to request a plot with mean ratio on the x-
axis. (The result parameter, here power, is always plotted on the other axis.) Use the
STEP= option in the PLOT statement to specify an interval of 0.05 between computed
points in the plot.

The following statements perform the desired analysis.

```plaintext
proc power;
   twosamplemeans test=ratio
      meanratio = 0.7 to 1.2 by 0.1
      nullratio = 1.10
      sides    = L
      alpha    = 0.01
      cv       = 0.5 0.6
      groupns  = (300 180)
      power    = .;
   plot x=effect step=0.05;
run;
```

Note the use of SIDES=L, which forces computations for cases that need a rejec-
tion region that is opposite to the one providing the most one-tailed power; in this
case, it is the lower tail. Such cases will show power that is less than the pre-
scribed Type 1 error rate. The default option DIST=LOGNORMAL specifies the
assumption of lognormally distributed data. The default MIN= and MAX= options
in the plot statement specify an x-axis range identical to the effect size range in the
TWOSAMPLEMEANS statement (mean ratios between 0.7 and 1.2).

See the output in Output 57.4.1 and Output 57.4.2.

The Computed Power table in Output 57.4.1 shows that power exceeds 0.90 if the true mean ratio is 90% or less, as surmised. But power is unacceptably low (0.31–0.42) if the processes happen to be truly equivalent. Note that the power is identical to the alpha level (0.01) if the true mean ratio is 1.10 and below 0.01 if the true mean ratio is appreciably worse (> 110%). In Output 57.4.2, the line style identifies the coefficient of variation. The plotting symbols identify locations of actual computed powers; the curves are linear interpolations of these points.

Example 57.5. Multiple Regression and Correlation

You are working with a team of preventive cardiologists investigating whether elevated serum homocysteine levels are linked to atherosclerosis (plaque buildup in coronary arteries). The planned analysis is an ordinary least squares regression to assess the relationship between total homocysteine level (tHcy) and a plaque burden index (PBI), adjusting for six other variables: age, gender, plasma levels of folate, vitamins $B_6$ and $B_{12}$, and a serum cholesterol index. You will regress PBI on tHcy and the six other predictors (plus the intercept) and use a Type III $F$ test to assess whether tHcy is a significant predictor after adjusting for the others. You wonder whether 100 subjects will provide adequate statistical power.

This is a correlational study at a single time. Subjects will be screened so that about half will have had a heart problem. All eight variables will be measured during one visit. Most clinicians are familiar with simple correlations between two variables, so you decide to pose the statistical problem in terms of estimating and testing the partial correlation between $X_1 = \text{tHcy}$ and $Y = \text{PBI}$, controlling for the six other predictor
variables \( (R_{Y,X_1|X_{-1}}) \). This greatly simplifies matters, especially the elicitation of the conjectured effect.

You use partial regression plots like that shown in Figure 57.9 to teach the team that the partial correlation between PBI and tHcy is the correlation of two sets of residuals obtained from ordinary regression models, one from regressing PBI on the six covariates and the other from regressing tHcy on the same covariates. Thus each subject has “expected” tHcy and PBI values based on the six covariates. The cardiologists believe that subjects who are relatively higher than expected on tHcy will also be relatively higher than expected on PBI. The partial correlation quantifies that adjusted association just like a standard simple correlation does with the unadjusted linear association between two variables.

\[
\rho = 0.35
\]

Based on previously published studies of various coronary risk factors and after viewing a set of scatterplots showing various correlations, the team surmises that the true partial correlation is likely to be at least 0.35.

You want to compute the statistical power for a sample size of \( N = 100 \), using \( \alpha = 0.05 \). You also want to plot power for sample sizes between 50 and 150. Use the MULTREG statement to compute the power and the PLOT statement to produce the graph. Since the predictors are observed rather than fixed in advanced, and a joint multivariate normal assumption seems tenable, use MODEL=RANDOM. The following statements perform the power analysis:
The `POWER=` option identifies power as the parameter to compute. The \texttt{NFULLPREDICTORS=} option specifies 7 total predictors (not including the intercept), and the \texttt{NTESTPREDICTORS=} option indicates that 1 of those predictors is being tested. The \texttt{PARTIALCORR=} and \texttt{NTOTAL=} options specify the partial correlation and sample size, respectively. The default value for the \texttt{ALPHA=} option sets the significance level to 0.05. The \texttt{X=N} option in the plot statement requests a plot of sample size on the x-axis, and the \texttt{MIN=} and \texttt{MAX=} options specify the sample size range.

Output 57.5.1 shows the output, and Output 57.5.2 shows the plot.

\begin{verbatim}
proc power;
    multreg
        model = random
        nfullpredictors = 7
        ntestpredictors = 1
        partialcorr = 0.35
        ntotal = 100
        power = .;
        plot x=n min=50 max=150;
run;
\end{verbatim}

Output 57.5.1. Power Analysis for Multiple Regression

\begin{tabular}{ll}
\hline
Method & \texttt{Exact} \\
Model & \texttt{Random X} \\
Number of Predictors in Full Model & 7 \\
Number of Test Predictors & 1 \\
Partial Correlation & 0.35 \\
Total Sample Size & 100 \\
Alpha & 0.05 \\
\hline
\end{tabular}

\begin{verbatim}
Computed Power
    Power
    0.939
\end{verbatim}
For the sample size \( N = 100 \), the study is almost balanced with respect to Type 1 and Type 2 error rates, with \( \alpha = 0.05 \) and \( \beta = 1 - 0.937 = 0.063 \). The study thus seems well designed at this sample size.

Now suppose that in a follow-up meeting with the cardiologists, you discover that their specific intent is to demonstrate that the (partial) correlation between PBI and \( t\text{Hcy} \) is greater than 0.2. You suggest changing the planned data analysis to a 1-sided Fisher’s \( z \) test with a null correlation of 0.2. The following statements perform a power analysis for this test:

```sas
proc power;
   onecorr dist=fisherz
      npvars = 6
      corr = 0.35
      nullcorr = 0.2
      sides = 1
      ntotal = 100
      power = .;
run;
```

The DIST=FISHERZ option in the ONECORR statement specifies Fisher’s \( z \) test. The NPVARS= option specifies that 6 additional variables are adjusted for in the partial correlation. The CORR= option specifies the conjectured correlation of 0.35, and the NULLCORR= option indicates the null value of 0.2. The SIDES= option specifies a 1-sided test.

Output 57.5.3 shows the output.
Output 57.5.3. Power Analysis for Fisher’s z Test

The power for Fisher’s z test is less than 50%, the decrease being mostly due to the smaller effect size (relative to the null value). When asked for a recommendation for a new sample size goal, you compute the required sample size to achieve a power of 0.95 (to balance Type 1 and Type 2 errors) and 0.85 (a threshold deemed to be minimally acceptable to the team). The following statements perform the sample size determination:

```plaintext
proc power;
  onecorr dist=fisherz
      npvars = 6
      corr  = 0.35
      nullcorr = 0.2
      sides  = 1
      ntotal = .
      power  = 0.85 0.95;
run;
```

The NTOTAL= option identifies sample size as the parameter to compute, and the POWER= option specifies the target powers.
Example 57.6. Comparing Two Survival Curves

You are consulting for a clinical research group planning a trial to compare survival rates for proposed and standard cancer treatments. The planned data analysis is a log-rank test to nonparametrically compare the overall survival curves for the two treatments. Your goal is to determine an appropriate sample size to achieve a power of 0.8 for a 2-sided test with $\alpha = 0.05$ using a balanced design.

The survival curve for patients on the standard treatment is well-known to be approximately exponential with a median survival time of five years. The research group conjectures that the new proposed treatment will yield a (nonexponential) survival curve similar to the dashed line in Output 57.6.1. Patients will be accrued uniformly over two years and then followed for an additional three years past the accrual period. Some loss to follow-up is expected, with roughly exponential rates that would result in about 50% loss with the standard treatment within 10 years. The loss to follow-up with the proposed treatment is more difficult to predict, but 50% loss would expected to occur sometime between years 5 and 20.

---

### Output 57.5.4. Sample Size Determination for Fisher’s z Test

<table>

<td>0.95</td>
<td>0.05</td>
<td>0.950</td>
<td>417</td>
<td></td>
</tr>
</tbody>
</table>

The results in Output 57.5.4 reveal a required sample size of 417 to achieve a power of 0.95 and 280 to achieve a power of 0.85.
Use the TWOSAMPLESURVIVAL statement with the TEST=LOGRANK option to compute the required sample size for the log-rank test. The following statements perform the analysis:

```bash
proc power;
  twosamplesurvival test=logrank
    curve("Standard") = 5 : 0.5
    curve("Proposed") = (1 to 5 by 1):(0.95 0.9 0.75 0.7 0.6)
    groupsurvival = "Standard" | "Proposed"
    accrualtime = 2
    followuptime = 3
    groupmedlosstimes = 10 | 20 5
    power = 0.8
    npergroup = .;
run;
```

The CURVE= option defines the two survival curves. The “Standard” curve has only one point, specifying an exponential form with a survival probability of 0.5 at year 5. The “Proposed” curve is a piecewise linear curve defined by the five points shown in Output 57.6.1. The GROUPSURVIVAL= option assigns the survival curves to the two groups, and the ACCRUALTIME= and FOLLOWUPTIME= options specify the accrual and follow-up times. The GROUPMEDLOSSTIMES= option specifies the years at which 50% loss is expected to occur. The POWER= option specifies the target power, and the NPERGROUP= option identifies sample size per group as the parameter to compute. Default values for the SIDES= and ALPHA= options specify a 2-sided test with $\alpha = 0.05$.

The required sample size per group to achieve a power of 0.8 is 228 if the median loss time is 20 years for the proposed treatment. Only six more patients are required in each group if the median loss time is as short as five years.

**Example 57.7. Confidence Interval Precision**

An investment firm has hired you to help plan a study to estimate the success of a new investment strategy called “IntuiVest.” The study involves complex simulations of market conditions over time, and it tracks the balance of a hypothetical brokerage account starting with $50,000. Each simulation is very expensive in terms of computing time. You are asked to determine an appropriate number of simulations to estimate the average change in the account balance at the end of three years. The goal is to have a 95% chance of obtaining a 90% confidence interval whose half-width is at most $1,000. That is, the firm wants to have a 95% chance of being able to correctly claim at the end of the study that “Our research shows with 90% confidence that IntuiVest yields a profit of $X +/- $1,000 at the end of three years on an initial investment of $50,000 (under simulated market conditions).”

The probability of achieving the desired precision (that is, a small interval width) can be calculated either unconditionally or conditionally given that the true mean is captured by the interval. You decide to use the conditional form, considering two of its advantages:
The conditional probability is usually lower than the unconditional probability for the same sample size, meaning that the conditional form is generally conservative.

The overall probability of achieving the desired precision and capturing the true mean is easily computed as the product of the half-width probability and the confidence level. In this case, the overall probability is $0.95 \times 0.9 = 0.855$.

Based on some initial simulations, you expect a standard deviation between $25,000$ and $45,000$ for the ending account balance. You will consider both of these values in the sample size analysis.

As mentioned in the “Overview of Power Concepts” section on page 3488, an analysis of confidence interval precision is analogous to a traditional power analysis, with “CI Half-Width” taking the place of effect size and “Prob(Width)” taking the place of power. In this example, the target CI Half-Width is 1000, and the desired Prob(Width) is 0.95.

In addition to computing sample sizes for a half-width of $1,000$, you are asked to plot the required number of simulations for a range of half-widths between $500$ and $2,000$. Use the ONESAMPLEMEANS statement with the CI=T option to implement the sample size determination. The following statements perform the analysis:

```sql
proc power;
  onesamplemeans ci=t
    alpha = 0.1
    halfwidth = 1000
    stddev = 25000 45000
    probwidth = 0.95
    ntotal = .;
    plot x=effect min=500 max=2000;
run;
```

The NTOTAL= option identifies sample size as the parameter to compute. The ALPHA=0.1 option specifies a confidence level of $1 - \alpha = 0.9$. The HALFWIDTH= option specifies the target half-width, and the STDDEV= option specifies the conjectured standard deviation values. The PROBWIDTH= option specifies the desired probability of achieving the target precision. The default value PROBTYPE=CONDITIONAL specifies that this probability is conditional on the true mean being captured by the interval. The default of SIDES=2 indicates a 2-sided interval.

Output 57.7.1 shows the output, and Output 57.7.2 shows the plot.

Output 57.7.2. Plot of Sample Size vs. Confidence Interval Half-Width

The number of simulations required in order to have a 95% chance of obtaining a half-width of at most 1000 is between 1788 and 5652, depending on the standard deviation. The plot reveals that over 20,000 simulations would be required for a half-width of 500 assuming the higher standard deviation.
**Example 57.8. Customizing Plots**

The example in this section demonstrates various ways you can modify and enhance plots:

- assigning analysis parameters to axes
- fine-tuning a sample size axis
- adding reference lines
- linking plot features to analysis parameters
- choosing key (legend) styles
- modifying symbol locations

The example plots are all based on a sample size analysis for a two-sample $t$ test of group mean difference. You start by computing the sample size required to achieve a power of 0.9 using a 2-sided test with $\alpha = 0.05$, assuming the first mean is 12, the second mean is either 15 or 18, and the standard deviation is either 7 or 9.

Use the TWOSAMPLEMEANS statement with the TEST=DIFF option to compute the required sample sizes. Indicate total sample size as the result parameter by supplying a missing value (.) with the NTOTAL= option. Use the GROUPMEANS=, STDDEV=, and POWER= option to specify values of the other parameters. The following statements perform the sample size computations.

```sas
proc power;
   twosamplemeans test=diff
      groupmeans = 12 | 15 18
      stddev = 7 9
      power = 0.9
      ntotal = .;
run;
```

Default values for the NULLDIFF=, SIDES=, GROUPWEIGHTS=, and DIST= options specify a null mean difference of 0, 2-sided test, balanced design, and assumption of normally distributed data.

Output 57.8.1 shows that the required sample size ranges from 60 to 382 depending on the unknown standard deviation and second mean.

Assigning Analysis Parameters to Axes

Use the PLOT statement to produce plots for all power and sample size analyses in PROC POWER. For the sample size analysis described at the beginning of this example, suppose you want to plot the required sample size on the y-axis against a range of powers between 0.5 and 0.95 on the x-axis. The X= and Y= options specify which parameter to plot against the result, and which axis to assign to this parameter. You can use either the X= or Y= option, but not both. Use the X=POWER option in PLOT statement to request a plot with power on the x-axis. The result parameter, here total sample size, is always plotted on the other axis. Use the MIN= and MAX= options to specify the range of the axis indicated with either the X= or the Y= option. Here, specify MIN=0.5 and MAX=0.95 to specify the power range. The following statements produce the plot.

```plaintext
proc power plotonly;
  twosamplemeans test=diff
      groupmeans = 12 | 15 18
      stddev    = 7 9
      power     = 0.9
      ntotal    = .;
  plot x=power min=0.5 max=0.95;
run;
```

Note that the value (0.9) of the POWER= option in the TWOSAMPLEMEANS statement is only a placeholder when the PLOTONLY option is used and both the MIN= and MAX= options are used, because the values of the MIN= and MAX= options
override the value of 0.9. But the POWER= option itself is still required in the
TWOSAMPLEMEANS statement, to provide a complete specification of the sam-
pel size analysis.

The resulting plot is shown in Output 57.8.2.

Output 57.8.2. Plot of Sample Size versus Power

The line style identifies the group means scenario, and the plotting symbol identifies
the standard deviation scenario. The locations of plotting symbols indicate computed
sample sizes; the curves are linear interpolations of these points. By default, each
curve consists of approximately 20 computed points (sometimes slightly more or
less, depending on the analysis).

If you would rather plot power on the y-axis versus sample size on the x-axis, you
have two general strategies to choose from. One strategy is to use the Y= option
instead of the X= option in the PLOT statement:

    plot y=power min=0.5 max=0.95;
Output 57.8.3. Plot of Power versus Sample Size using First Strategy

Note that the resulting plot (Output 57.8.3) is essentially a mirror image of Output 57.8.2. The axis ranges are set such that each curve in Output 57.8.3 contains similar values of Y instead of X. Each plotted point represents the computed value of the x-axis at the input value of the y-axis.

A second strategy for plotting power versus sample size (when originally solving for sample size) is to invert the analysis and base the plot on computed power for a given range of sample sizes. This strategy works well for monotonic power curves (as is the case for the t test and most other continuous analyses). It is advantageous in the sense of preserving the traditional role of the y-axis as the computed parameter. A common way to implement this strategy is

- Determine the range of sample sizes sufficient to cover at the desired power range for all curves (where each “curve” represents a scenario for standard deviation and second group mean).
- Use this range for the x-axis of a plot.

To determine the required sample sizes for target powers of 0.5 and 0.95, change the values in the POWER= option to reflect this range:
Output 57.8.4 reveals that a sample size range of 24 to 470 is approximately sufficient to cover the desired power range of 0.5 to 0.95 for all curves ("approximately" because the actual power at the rounded sample size of 24 is slightly higher than the nominal power of 0.5).

Output 57.8.4.  Computed Sample Sizes

<table>
<thead>

<td>0.952</td>
<td>120</td>
</tr>
</tbody>
</table>

To plot power on the y-axis for sample sizes between 20 and 500, use the X=N option in the PLOT statement with MIN=20 and MAX=500:

```
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 15 18
    stddev = 7 9
    power = .
    ntotal = 200;
  plot x=n min=20 max=500;
run;
```
Each curve in the resulting plot in Output 57.8.5 covers at least a power range of 0.5 to 0.95.

**Output 57.8.5.** Plot of Power versus Sample Size Using Second Strategy

Finally, suppose you want to produce a plot of sample size versus effect size for a power of 0.9. In this case, the “effect size” is defined to be the mean difference. You need to reparameterize the analysis by using the MEANDIFF= option instead of the GROUPMEANS= option to produce a plot, since each plot axis must be represented by a scalar parameter. Use the X=EFFECT option in the PLOT statement to assign the mean difference to the x-axis. The following statements produce a plot of required sample size to detect mean differences between 3 and 6.

```plaintext
proc power plotonly;
   twosamplemeans test=diff
   meandiff   = 3 6
   stddev     = 7 9
   power      = 0.9
   ntotal     = .;
   plot x=effect min=3 max=6;
run;
```

The resulting plot Output 57.8.6 shows how the required sample size decreases with increasing mean difference.
Output 57.8.6.  Plot of Sample Size versus Mean Difference

Fine-Tuning a Sample Size Axis

Consider the following plot request for a sample size analysis similar to the one in Output 57.8.1 but with only a single scenario, and with unbalanced sample size allocation of 2:1.

```sas
proc power plotonly;
   ods output plotcontent=PlotData;
   twosamplemeans test=diff
      groupmeans = 12 | 18
      stddev     = 7
      groupweights = 2 | 1
      power      = .
      ntotal    = 20;
      plot x=n min=20 max=50 npoints=20;
run;
```

The MIN=, MAX=, and NPOINTS= options in the PLOT statement request a plot with 20 points between 20 and 50. But the resulting plot (Output 57.8.7) appears to have only 11 points, and they range from 18 to 48.
The reason that this plot has fewer points than usual is due to the rounding of sample sizes. If you do not use the NFRATIONAL option in the analysis statement (here, the TWOSAMPLEMEANS statement), then the set of sample size points determined by the MIN=, MAX=, NPOINTS=, and STEP= options in the PLOT statement may be rounded to satisfy the allocation weights. In this case, they are rounded down to the nearest multiples of 3 (the sum of the weights), and many of the points overlap. To see the overlap, you can print the NominalNTotal (unadjusted) and NTotal (rounded) variables in the PlotContent ODS object (here saved to a data set called PlotData):

```latex
proc print data=PlotData;
  var NominalNTotal NTotal;
run;
```

The output is shown in Output 57.8.8.
Besides overlapping of sample size points, another peculiarity that might occur without the NFRATIONAL option is unequal spacing; for example, in the plot in Output 57.8.9, created with the following statements.

```sas
proc power plotonly;
    twosamplemeans test=diff
        groupmeans = 12 | 18
        stddev = 7
        groupweights = 2 | 1
        power = .
        ntotal = 20;
    plot x=n min=20 max=50 npoints=5;
run;
```
Output 57.8.9. Plot with Unequally Spaced Points

If you want to guarantee evenly spaced, nonoverlapping sample size points in your plots, you can either (1) use the NFRACTIONAL option in the analysis statement preceding the PLOT statement, or (2) use the STEP= option and provide values for the MIN=, MAX=, and STEP= options in the PLOT statement that are multiples of the sum of the allocation weights. Note that this sum is simply 1 for one-sample and paired designs and 2 for balanced two-sample designs. So, any integer step value works well for one-sample and paired designs, and any even step value works well for balanced two-sample designs. Both of these strategies will avoid rounding adjustments.

The following statements implement the first strategy to create the plot in Output 57.8.10, using the NFRACTIONAL option in the TWOSAMPLEMEANS statement.

```sas
proc power plotonly;
   twosamplemeans test=diff
      nfrational
      groupmeans = 12 | 18
      stddev = 7
      groupweights = 2 | 1
      power = .
      ntotal = 20;
   plot x=n min=20 max=50 npoints=20;
run;
```
To implement the second strategy, use multiples of 3 for the STEP=, MIN=, and MAX= options in the PLOT statement (because the sum of the allocation weights is $2 + 1 = 3$). The following statements use STEP=3, MIN=18, and MAX=48 to create a plot that looks identical to Output 57.8.7 but suffers no overlapping of points.

```latex
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 18
    stddev = 7
    groupweights = 2 | 1
    power = .
    ntotal = 20;
  plot x=n min=18 max=48 step=3;
run;
```

### Adding Reference Lines

Suppose you want to add reference lines to highlight power=0.8 and power=0.9 on the plot in Output 57.8.5. You can add simple reference lines using the YOPTS= option and REF= sub-option in the PLOT statement to produce Output 57.8.11, using the following statements.

```latex
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 15 18
```
or, you can specify CROSSREF=YES to add reference lines that intersect each curve and cross over to the other axis:

```plaintext
plot x=n min=20 max=500
    yopts=(ref=0.8 0.9 crossref=yes);
```

the resulting plot is shown in output 57.8.12.
You can also add reference lines for the x-axis by using the XOPTS= option instead of the YOPTS= option. For example, the following plot statement produces Output 57.8.13, which has crossing reference lines highlighting the sample size of 100.

```
plot x=n min=20 max=500
  xopts=(ref=100 crossref=yes);
```
Output 57.8.13. Plot with CROSSREF=YES Style Reference Lines from X-Axis

**Linking Plot Features to Analysis Parameters**

You can use the VARY option in the PLOT statement to specify which of the following features you wish to associate with analysis parameters.

- line style
- plotting symbol
- color
- panel

You can specify mappings between each of these features and one or more analysis parameters, or you can simply choose a subset of these features to use (and rely on default settings to associate these features with multiple-valued analysis parameters).

Suppose you supplement the sample size analysis in Output 57.8.5 to include three values of alpha, using the following statements.
Chapter 57. The POWER Procedure

```sas
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 15 18
    stddev = 7 9
    alpha = 0.01 0.025 0.1
    power = .
    ntotal = 100;
  plot x=n min=20 max=500;
run;
```

The defaults for the VARY option in the PLOT statement specify line style varying by the ALPHA= parameter, plotting symbol varying by the GROUPMEANS= parameter, panel varying by the STDDEV= parameter, and color remaining constant. The resulting plot, consisting of two panels, is shown in Output 57.8.14 and Output 57.8.15.

**Output 57.8.14.** Plot with Default VARY Settings: Panel 1 of 2
Output 57.8.15. Plot with Default VARY Settings: Panel 2 of 2

Suppose you want to produce a plot with only one panel that varies color in addition to line style and plotting symbol. Include the LINESTYLE, SYMBOL, and COLOR keywords in the VARY option in the PLOT statement, as follows, to produce the plot in Output 57.8.16.

```
plot x=n min=20 max=500
  vary (linestyle, symbol, color);
```
Finally, suppose you want to specify which features are used and which analysis parameters they are linked to. The following PLOT statement produces a two-panel plot (shown in Output 57.8.17 and Output 57.8.18) in which line style varies by standard deviation, plotting symbol varies by both alpha and sides, and panel varies by means.

\[
\text{plot x=n min=20 max=500}
\text{ vary (linestyle by stddev,}
\text{ symbol by alpha sides,}
\text{ panel by groupmeans);}
\]
Output 57.8.17.  Plot with Features ExplicitlyLinked to Parameters: Panel 1 of 2

Output 57.8.18.  Plot with Features Explicitly Linked to Parameters: Panel 2 of 2
Choosing Key (Legend) Styles

The default style for the key (or “legend”) is one that displays the association between levels of features and levels of analysis parameters, located below the x-axis. For example, Output 57.8.5 demonstrates this style of key.

You can reproduce Output 57.8.5 with the same key but a different location, inside the plotting region, using the POS=INSET option within the KEY=BYFEATURE option in the PLOT statement. The following statements produce the plot in Output 57.8.19.

```
proc power plotonly;
   twosamplemeans test=diff
     groupmeans = 12 | 15 18
     stddev = 7 9
     power = .
     ntotal = 200;
   plot x=n min=20 max=500
     key = byfeature(pos=inset);
run;
```

Output 57.8.19.  Plot with a By-Feature Key Inside the Plotting Region

Alternatively, you can specify a key that identifies each individual curve separately by number using the KEY=BYCURVE option in the PLOT statement:

```
plot x=n min=20 max=500
   key = bycurve;
```
The resulting plot is shown in Output 57.8.20.

**Output 57.8.20.** Plot with a Numbered By-Curve Key

![Plot with a Numbered By-Curve Key](image)

Use the NUMBERS=OFF option within the KEY=BYCURVE option to specify a nonnumbered key that identifies curves with samples of line styles, symbols, and colors:

```
plot x=n min=20 max=500
  key = bycurve(numbers=off pos=inset);
```

The POS=INSET suboption places the key within the plotting region. The resulting plot is shown in Output 57.8.21.
Finally, you can attach labels directly to curves with the KEY=ONCURVES option. The following plot statement produces Output 57.8.22.

```r
plot x=n min=20 max=500
key = oncurves;
```
Output 57.8.22. Plot with Directly Labeled Curves

Modifying Symbol Locations

The default locations for plotting symbols are the points computed directly from the power and sample size algorithms. For example, Output 57.8.5 shows plotting symbols corresponding to computed points. The curves connecting these points are interpolated (as indicated by the INTERPOL= option in the PLOT statement).

You can modify the locations of plotting symbols using the MARKERS= option in the plot statement. The MARKERS=ANALYSIS option places plotting symbols at locations corresponding to the input specified in the analysis statement preceding the PLOT statement. You may prefer this as an alternative to using reference lines to highlight specific points. For example, you can reproduce Output 57.8.5, but with the plotting symbols located at the sample sizes shown in Output 57.8.1, using the following statements.

```plaintext
proc power plotonly;
  twosamplemeans test=diff
    groupmeans = 12 | 15 18
    stddev = 7 9
    power = .
    ntotal = 232 382 60 98;
  plot x=n min=20 max=500
    markers=analysis;
run;
```

The analysis statement here is the TWOSAMPLEMEANS statement. The MARKERS=ANALYSIS option in the PLOT statement causes the plotting
symbols to occur at sample sizes specified by the NTOTAL= option in the
TWOSAMPLEMEANS statement: 232, 382, 60, and 98. The resulting plot is shown
in Output 57.8.23.

**Output 57.8.23.** Plot with MARKERS=ANALYSIS

![Plot with MARKERS=ANALYSIS](image)

You can also use the MARKERS=NICE option to align symbols with the tick marks
on one of the axes (the x-axis when the X= option is used, or the y-axis when the Y=
is used):

```
plot x=n min=20 max=500
    markers=nice;
```

The plot created by this PLOT statement is shown in Output 57.8.24.
**Output 57.8.24.** Plot with MARKERS=NICE

Note that the plotting symbols are aligned with the tick marks on the x-axis because the X= option is specified.

**References**

The PRINCOMP procedure performs principal component analysis. As input you can use raw data, a correlation matrix, a covariance matrix, or a sums of squares and crossproducts (SSCP) matrix. You can create output data sets containing eigenvalues, eigenvectors, and standardized or unstandardized principal component scores.

Principal component analysis is a multivariate technique for examining relationships among several quantitative variables. The choice between using factor analysis and principal component analysis depends in part upon your research objectives. You should use the PRINCOMP procedure if you are interested in summarizing data and detecting linear relationships. Plots of principal components are especially valuable tools in exploratory data analysis. You can use principal components to reduce the number of variables in regression, clustering, and so on. See Chapter 5, “Introduction to Multivariate Procedures,” for a detailed comparison of the PRINCOMP and FACTOR procedures.

Experimental graphics are now available with the PRINCOMP procedure. For more information, see the “ODS Graphics” section on page 3613.

Principal component analysis was originated by Pearson (1901) and later developed by Hotelling (1933). The application of principal components is discussed by Rao (1964), Cooley and Lohnes (1971), and Gnanadesikan (1977). Excellent statistical treatments of principal components are found in Kshirsagar (1972), Morrison (1976), and Mardia, Kent, and Bibby (1979).

Given a data set with \( p \) numeric variables, you can compute \( p \) principal components. Each principal component is a linear combination of the original variables, with coefficients equal to the eigenvectors of the correlation or covariance matrix. The eigenvectors are customarily taken with unit length. The principal components are sorted by descending order of the eigenvalues, which are equal to the variances of the components.

Principal components have a variety of useful properties (Rao 1964; Kshirsagar 1972):

- The eigenvectors are orthogonal, so the principal components represent jointly perpendicular directions through the space of the original variables.
- The principal component scores are jointly uncorrelated. Note that this property is quite distinct from the previous one.
- The first principal component has the largest variance of any unit-length linear combination of the observed variables. The \( j \)th principal component has the largest variance of any unit-length linear combination orthogonal to the first
Chapter 58. The PRINCOMP Procedure

$j - 1$ principal components. The last principal component has the smallest variance of any linear combination of the original variables.

- The scores on the first $j$ principal components have the highest possible generalized variance of any set of unit-length linear combinations of the original variables.
- The first $j$ principal components provide a least-squares solution to the model

\[ Y = XB + E \]

where $Y$ is an $n \times p$ matrix of the centered observed variables; $X$ is the $n \times j$ matrix of scores on the first $j$ principal components; $B$ is the $j \times p$ matrix of eigenvectors; $E$ is an $n \times p$ matrix of residuals; and you want to minimize $\text{trace}(E' E)$, the sum of all the squared elements in $E$. In other words, the first $j$ principal components are the best linear predictors of the original variables among all possible sets of $j$ variables, although any nonsingular linear transformation of the first $j$ principal components would provide equally good prediction. The same result is obtained if you want to minimize the determinant or the Euclidean (Schur, Frobenious) norm of $E' E$ rather than the trace.

- In geometric terms, the $j$-dimensional linear subspace spanned by the first $j$ principal components provides the best possible fit to the data points as measured by the sum of squared perpendicular distances from each data point to the subspace. This is in contrast to the geometric interpretation of least squares regression, which minimizes the sum of squared vertical distances. For example, suppose you have two variables. Then, the first principal component minimizes the sum of squared perpendicular distances from the points to the first principal axis. This is in contrast to least squares, which would minimize the sum of squared vertical distances from the points to the fitted line.

Principal component analysis can also be used for exploring polynomial relationships and for multivariate outlier detection (Gnanadesikan 1977), and it is related to factor analysis, correspondence analysis, allometry, and biased regression techniques (Mardia, Kent, and Bibby 1979).

Getting Started

The following example uses the PRINCOMP procedure to analyze job performance. Police officers were rated by their supervisors in 14 categories as part of standard police departmental administrative procedure.

The following statements create the Jobratings data set:

```plaintext
options validvarname=any;
data Jobratings;
input ('Communication Skills'n
'Problem Solving'n
'Learning Ability'n
```

- The scores on the first $j$ principal components have the highest possible generalized variance of any set of unit-length linear combinations of the original variables.
- The first $j$ principal components provide a least-squares solution to the model

\[ Y = XB + E \]

where $Y$ is an $n \times p$ matrix of the centered observed variables; $X$ is the $n \times j$ matrix of scores on the first $j$ principal components; $B$ is the $j \times p$ matrix of eigenvectors; $E$ is an $n \times p$ matrix of residuals; and you want to minimize $\text{trace}(E' E)$, the sum of all the squared elements in $E$. In other words, the first $j$ principal components are the best linear predictors of the original variables among all possible sets of $j$ variables, although any nonsingular linear transformation of the first $j$ principal components would provide equally good prediction. The same result is obtained if you want to minimize the determinant or the Euclidean (Schur, Frobenious) norm of $E' E$ rather than the trace.

- In geometric terms, the $j$-dimensional linear subspace spanned by the first $j$ principal components provides the best possible fit to the data points as measured by the sum of squared perpendicular distances from each data point to the subspace. This is in contrast to the geometric interpretation of least squares regression, which minimizes the sum of squared vertical distances. For example, suppose you have two variables. Then, the first principal component minimizes the sum of squared perpendicular distances from the points to the first principal axis. This is in contrast to least squares, which would minimize the sum of squared vertical distances from the points to the fitted line.

Principal component analysis can also be used for exploring polynomial relationships and for multivariate outlier detection (Gnanadesikan 1977), and it is related to factor analysis, correspondence analysis, allometry, and biased regression techniques (Mardia, Kent, and Bibby 1979).

Getting Started

The following example uses the PRINCOMP procedure to analyze job performance. Police officers were rated by their supervisors in 14 categories as part of standard police departmental administrative procedure.

The following statements create the Jobratings data set:

```plaintext
options validvarname=any;
data Jobratings;
input ('Communication Skills'n
'Problem Solving'n
'Learning Ability'n
```
'Judgment Under Pressure’n
'Obersvational Skills’n
'Willingness to Confront Problems’n
'Interest in People’n
'Intepercnonal Senfcivity’n
'Desire for Self-Improvement’n
'Appearance’n
'Dependability’n
'Physical Ability’n
'Integrity’n
'Overall Rating’n) (1.);

datalines;
26838853879867
74758876857667
56757863775875
67869777988997
...
99899899989989
76656399567486
;

The data set Jobratings contains 14 variables. Each variable contains the job ratings using a scale measurement from 1 to 10 (1=fail to comply, 10=exceptional). The last variable Overall Rating contains a score as an overall index on how each officer performs.

The following statement requests a principal component analysis on the Jobratings data set and outputs the scores to the Scores data set (OUT= Scores). Note that variable Overall Rating is excluded from the analysis.

    proc princomp data=Jobratings(drop=`Overall Rating’n) out=scores;
    run;

Figure 58.1 to Figure 58.3 display the PROC PRINCOMP output, beginning with simple statistics followed by the correlation matrix. The PROC PRINCOMP statement requests by default principal components computed from the correlation matrix, so the total variance is equal to the number of variables, 13. In this example, it would also be reasonable to use the COV option, which would cause variables with a high variance (such as Dependability) to have more influence on the results than variables with a low variance (such as Learning Ability). If you used the COV option, scores would be computed from centered rather than standardized variables.

**Figure 58.3.** (Continued) Correlation Matrix from the PRINCOMP Procedure

Figure 58.4 displays the eigenvalues. The first principal component explains about 50% of the total variance, the second principal component explains about 13.6%, and the third principal component explains about 7.7%. Note that the eigenvalues sum to the total variance. The eigenvalues indicate that three to five components provide a good summary of the data, with three components accounting for about 71.7% of the total variance and five components explaining about 82.7%. Subsequent components contribute less than 5% each.

Figure 58.4. Eigenvectors from the PRINCOMP Procedure

Figure 58.5 and Figure 58.6 display the eigenvectors. From the eigenvectors matrix, you can represent the first principal component Prin1 as a linear combination of the original variables

\[
\text{Prin1} = 0.303548 \times (\text{Communication Skills}) + 0.278034 \times (\text{Problem Solving}) + 0.266521 \times (\text{Learning Ability}) + 0.298246 \times (\text{Integrity})
\]

and, similarly, the second principal component Prin2 is

\[
\text{Prin2} = 0.052039 \times (\text{Communication Skills}) + 0.057046 \times (\text{Problem Solving}) + 0.288152 \times (\text{Learning Ability}) - 0.301812 \times (\text{Integrity})
\]

where the variables are standardized.

Figure 58.6. (Continued) Eigenvectors from the PRINCOMP Procedure

The first component reflects overall performance since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on the variables Observational Skills and Willingness to Confront Problems but even higher negative loadings on the variables Interest in People and Interpersonal Sensitivity. This component seems to reflect the ability to take action, but it also reflects a lack of interpersonal skills. The third eigenvector has a very high positive loading on the variable Physical Ability and high negative loadings on the variables Problem Solving and Learning Ability. This component seems to reflect physical strength, but also shows poor learning and problem-solving skills.

In short, the three components represent:

First Component: overall performance
Second Component: smart, tough, and introverted
Third Component: superior strength and average intellect
The following statements are available in PROC PRINCOMP.

**PROC PRINCOMP < options > ;**
- **BY variables ;**
- **FREQ variable ;**
- **PARTIAL variables ;**
- **VAR variables ;**
- **WEIGHT variable ;**

Usually only the VAR statement is used in addition to the PROC PRINCOMP statement. The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC PRINCOMP statement. The remaining statements are described in alphabetical order.

### PROC PRINCOMP Statement

**PROC PRINCOMP < options > ;**

The PROC PRINCOMP statement starts the PRINCOMP procedure and, optionally, identifies input and output data sets, specifies details of the analysis, or suppresses the display of output. You can specify the following options in the PROC PRINCOMP statement.

<table>
<thead>
<tr>
<th>Task</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify data sets</td>
<td>DATA=</td>
</tr>
<tr>
<td></td>
<td>OUT=</td>
</tr>
<tr>
<td></td>
<td>OUTSTAT=</td>
</tr>
<tr>
<td>Specify details of analysis</td>
<td>COV</td>
</tr>
<tr>
<td></td>
<td>N=</td>
</tr>
<tr>
<td></td>
<td>NOINT</td>
</tr>
<tr>
<td></td>
<td>PREFIX=</td>
</tr>
<tr>
<td></td>
<td>SINGULAR=</td>
</tr>
<tr>
<td></td>
<td>STD</td>
</tr>
<tr>
<td></td>
<td>VARDEF=</td>
</tr>
<tr>
<td>Suppress the display of output</td>
<td>NOPRINT</td>
</tr>
</tbody>
</table>

The following list provides details on these options.

**COVARIANCE**

**COV**

computes the principal components from the covariance matrix. If you omit the COV option, the correlation matrix is analyzed. Use of the COV option causes variables with large variances to be more strongly associated with components with large eigenvalues and causes variables with small variances to be more strongly associated with
PROC PRINCOMP Statement

components with small eigenvalues. You should not specify the COV option unless the units in which the variables are measured are comparable or the variables are standardized in some way.

**DATA=SAS-data-set**
specifies the SAS data set to be analyzed. The data set can be an ordinary SAS data set or a TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV data set (see Appendix A, “Special SAS Data Sets,”). Also, the PRINCOMP procedure can read the _TYPE_ = ’COVB’ matrix from a TYPE=EST data set. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**N=number**
specifies the number of principal components to be computed. The default is the number of variables. The value of the N= option must be an integer greater than or equal to zero.

**NOINT**
omits the intercept from the model. In other words, the NOINT option requests that the covariance or correlation matrix not be corrected for the mean. When you use the PRINCOMP procedure with the NOINT option, the covariance matrix and, hence, the standard deviations are not corrected for the mean. If you are interested in the standard deviations corrected for the mean, you can get them by using a procedure such as the MEANS procedure.

If you use a TYPE=SSCP data set as input to the PRINCOMP procedure and list the variable Intercept in the VAR statement, the procedure acts as if you had also specified the NOINT option. If you use NOINT and also create an OUTSTAT= data set, the data set is TYPE=UCORR or TYPE=UCOV rather than TYPE=CORR or TYPE=COV.

**NOPRINT**
suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

**OUT=SAS-data-set**
creates an output SAS data set that contains all the original data as well as the principal component scores. If you want to create a permanent SAS data set, you must specify a two-level name (refer to *SAS Language Reference: Concepts* for information on permanent SAS data sets).

**OUTSTAT=SAS-data-set**
creates an output SAS data set that contains means, standard deviations, number of observations, correlations or covariances, eigenvalues, and eigenvectors. If you specify the COV option, the data set is TYPE=COV or TYPE=UCOV, depending on the NOINT option, and it contains covariances; otherwise, the data set is TYPE=CORR or TYPE=UCORR, depending on the NOINT option, and it contains correlations. If you specify the PARTIAL statement, the OUTSTAT= data set contains $R$-squares as well. If you want to create a permanent SAS data set, you must specify a two-level
name (refer to SAS Language Reference: Concepts for information on permanent SAS data sets).

**PREFIX=name**
specifies a prefix for naming the principal components. By default, the names are Prin1, Prin2, ..., Prinₙ. If you specify PREFIX=ABC, the components are named ABC1, ABC2, ABC3, and so on. The number of characters in the prefix plus the number of digits required to designate the variables should not exceed the current name length defined by the VALIDVARNAME= system option.

**SINGULAR=p**
**SING=p**
specifies the singularity criterion, where 0 < p < 1. If a variable in a PARTIAL statement has an R-square as large as 1 − p when predicted from the variables listed before it in the statement, the variable is assigned a standardized coefficient of 0. By default, SINGULAR=1E−8.

**STANDARD**
**STD**
standardizes the principal component scores in the OUT= data set to unit variance. If you omit the STANDARD option, the scores have variance equal to the corresponding eigenvalue. Note that STANDARD has no effect on the eigenvalues themselves.

**VARDEF=DF | N | WDF | WEIGHT | WGT**
specifies the divisor used in calculating variances and standard deviations. By default, VARDEF=DF. The following table displays the values and associated divisors.

<table>
<thead>
<tr>
<th>Value</th>
<th>Divisor</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>DF</td>
<td>error degrees of freedom</td>
<td>( n - i ) (before partialling) ( n - p - i ) (after partialling)</td>
</tr>
<tr>
<td>N</td>
<td>number of observations</td>
<td>( n )</td>
</tr>
<tr>
<td>WEIGHT</td>
<td>WGT</td>
<td>sum of weights</td>
</tr>
<tr>
<td>WDF</td>
<td>sum of weights minus one</td>
<td>( \left( \sum_{j=1}^{n} w_j \right) - i ) (before partialling) ( \left( \sum_{j=1}^{n} w_j \right) - p - i ) (after partialling)</td>
</tr>
</tbody>
</table>

In the formulas for VARDEF=DF and VARDEF=WDF, \( p \) is the number of degrees of freedom of the variables in the PARTIAL statement, and \( i \) is 0 if the NOINT option is specified and 1 otherwise.
BY Statement

BY variables;

You can specify a BY statement with PROC PRINCOMP to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PRINCOMP procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

FREQ Statement

FREQ variable;

The FREQ statement specifies a variable that provides frequencies for each observation in the DATA= data set. Specifically, if \( n \) is the value of the FREQ variable for a given observation, then that observation is used \( n \) times.

The analysis produced using a FREQ statement reflects the expanded number of observations. The total number of observations is considered equal to the sum of the FREQ variable. You could produce the same analysis (without the FREQ statement) by first creating a new data set that contains the expanded number of observations. For example, if the value of the FREQ variable is 5 for the first observation, the first 5 observations in the new data set would be identical. Each observation in the old data set would be replicated \( n_j \) times in the new data set, where \( n_j \) is the value of the FREQ variable for that observation.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.
PARTIAL Statement

PARTIAL variables;

If you want to analyze a partial correlation or covariance matrix, specify the names of the numeric variables to be partialled out in the PARTIAL statement. The PRINCOMP procedure computes the principal components of the residuals from the prediction of the VAR variables by the PARTIAL variables. If you request an OUT= or OUTSTAT= data set, the residual variables are named by prefixing the characters R_ to the VAR variables. Thus, the number of characters required to distinguish the VAR variables should be, at most, two characters fewer than the current name length defined by the VALIDVARNAME= system option.

VAR Statement

VAR variables;

The VAR statement lists the numeric variables to be analyzed. If you omit the VAR statement, all numeric variables not specified in other statements are analyzed. If, however, the DATA= data set is TYPE=SSCP, the default set of variables used as VAR variables does not include Intercept so that the correlation or covariance matrix is constructed correctly. If you want to analyze Intercept as a separate variable, you should specify it in the VAR statement.

WEIGHT Statement

WEIGHT variable;

If you want to use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the weight variable are proportional to the reciprocals of the variances.

The observation is used in the analysis only if the value of the WEIGHT statement variable is nonmissing and is greater than zero.

Details

Missing Values

Observations with missing values for any variable in the VAR, PARTIAL, FREQ, or WEIGHT statement are omitted from the analysis and are given missing values for principal component scores in the OUT= data set. If a correlation, covariance, or SSCP matrix is read, it can contain missing values as long as every pair of variables has at least one nonmissing entry.
Output Data Sets

OUT= Data Set

The OUT= data set contains all the variables in the original data set plus new variables containing the principal component scores. The N= option determines the number of new variables. The names of the new variables are formed by concatenating the value given by the PREFIX= option (or Prin if PREFIX= is omitted) and the numbers 1, 2, 3, and so on. The new variables have mean 0 and variance equal to the corresponding eigenvalue, unless you specify the STANDARD option to standardize the scores to unit variance. Also, if you specify the COV option, the procedure computes the principal component scores from the corrected or the uncorrected (if the NOINT option is specified) variables rather than the standardized variables.

If you use a PARTIAL statement, the OUT= data set also contains the residuals from predicting the VAR variables from the PARTIAL variables. The names of the residual variables are formed by prefixing R– to the names of the VAR variables.

An OUT= data set cannot be created if the DATA= data set is TYPE=ACE, TYPE=CORR, TYPE=COV, TYPE=EST, TYPE=FACTOR, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV.

OUTSTAT= Data Set

The OUTSTAT= data set is similar to the TYPE=CORR data set produced by the CORR procedure. The following table relates the TYPE= value for the OUTSTAT= data set to the options specified in the PROC PRINCOMP statement.

<table>
<thead>
<tr>
<th>Options</th>
<th>TYPE=</th>
</tr>
</thead>
<tbody>
<tr>
<td>(default)</td>
<td>CORR</td>
</tr>
<tr>
<td>COV</td>
<td>COV</td>
</tr>
<tr>
<td>NOINT</td>
<td>UCORR</td>
</tr>
<tr>
<td>COV NOINT</td>
<td>UCOV</td>
</tr>
</tbody>
</table>

Notice that the default (neither the COV nor NOINT option) produces a TYPE=CORR data set.

The new data set contains the following variables:

- the BY variables, if any
- two new variables, _TYPE_ and _NAME_, both character variables
- the variables analyzed, that is, those in the VAR statement; or, if there is no VAR statement, all numeric variables not listed in any other statement; or, if there is a PARTIAL statement, the residual variables as described under the OUT= data set

Each observation in the new data set contains some type of statistic as indicated by the _TYPE_ variable. The values of the _TYPE_ variable are as follows:
<table>
<thead>
<tr>
<th>TYPE</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEAN</td>
<td>Mean of each variable. If you specify the PARTIAL statement, this observation is omitted.</td>
</tr>
<tr>
<td>STD</td>
<td>Standard deviations. If you specify the COV option, this observation is omitted, so the SCORE procedure does not standardize the variables before computing scores. If you use the PARTIAL statement, the standard deviation of a variable is computed as its root mean squared error as predicted from the PARTIAL variables.</td>
</tr>
<tr>
<td>USTD</td>
<td>Uncorrected standard deviations. When you specify the NOINT option in the PROC PRINCOMP statement, the OUTSTAT= data set contains standard deviations not corrected for the mean. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.</td>
</tr>
<tr>
<td>N</td>
<td>Number of observations on which the analysis is based. This value is the same for each variable. If you specify the PARTIAL statement and the value of the VARDEF= option is DF or unspecified, then the number of observations is decremented by the degrees of freedom for the PARTIAL variables.</td>
</tr>
<tr>
<td>SUMWGT</td>
<td>The sum of the weights of the observations. This value is the same for each variable. If you specify the PARTIAL statement and VARDEF=WDF, then the sum of the weights is decremented by the degrees of freedom for the PARTIAL variables. This observation is output only if the value is different from that in the observation with <em>TYPE</em>='N'.</td>
</tr>
<tr>
<td>CORR</td>
<td>Correlations between each variable and the variable specified by the <em>NAME</em> variable. The number of observations with <em>TYPE</em>='CORR' is equal to the number of variables being analyzed. If you specify the COV option, no <em>TYPE</em>='CORR' observations are produced. If you use the PARTIAL statement, the partial correlations, not the raw correlations, are output.</td>
</tr>
<tr>
<td>UCORR</td>
<td>Uncorrected correlation matrix. When you specify the NOINT option without the COV option in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of correlations not corrected for the means. However, if you also specify the COV option in the PROC PRINCOMP statement, this observation is omitted.</td>
</tr>
<tr>
<td>COV</td>
<td>Covariances between each variable and the variable specified by the <em>NAME</em> variable. <em>TYPE</em>='COV' observations are produced only if you specify the COV option. If you use the PARTIAL statement, the partial covariances, not the raw covariances, are output.</td>
</tr>
<tr>
<td>UCOV</td>
<td>Uncorrected covariance matrix. When you specify the NOINT and COV options in the PROC PRINCOMP statement, the OUTSTAT= data set contains a matrix of covariances not corrected for the means.</td>
</tr>
<tr>
<td>EIGENVAL</td>
<td>Eigenvalues. If the N= option requested fewer than the maximum number of principal components, only the specified number of eigenvalues are produced, with missing values filling out the observation.</td>
</tr>
</tbody>
</table>
SCORE eigenvectors. The _NAME_ variable contains the name of the corresponding principal component as constructed from the PREFIX= option. The number of observations with _TYPE_='SCORE' equals the number of principal components computed. The eigenvectors have unit length unless you specify the STD option, in which case the unit-length eigenvectors are divided by the square roots of the eigenvalues to produce scores with unit standard deviations.

To obtain the principal component scores, if the COV option is not specified, these coefficients should be multiplied by the standardized data. With the COV option, these coefficients should be multiplied by the centered data. Means obtained from the observation with _TYPE_='MEAN' and standard deviations obtained from the observation with _TYPE_='STD' should be used for centering and standardizing the data.

USCORE scoring coefficients to be applied without subtracting the mean from the raw variables. _TYPE_='USCORE' observations are produced when you specify the NOINT option in the PROC PRINCOMP statement.

To obtain the principal component scores, these coefficients should be multiplied by the data that are standardized by the uncorrected standard deviations obtained from the observation with _TYPE_='USTD'.

RSQUARED R-squares for each VAR variable as predicted by the PARTIAL variables

B regression coefficients for each VAR variable as predicted by the PARTIAL variables. This observation is produced only if you specify the COV option.

STB standardized regression coefficients for each VAR variable as predicted by the PARTIAL variables. If you specify the COV option, this observation is omitted.

The data set can be used with the SCORE procedure to compute principal component scores, or it can be used as input to the FACTOR procedure specifying METHOD=SCORE to rotate the components. If you use the PARTIAL statement, the scoring coefficients should be applied to the residuals, not the original variables.

### Computational Resources

Let

\[
\begin{align*}
n & = \text{number of observations} \\
v & = \text{number of VAR variables} \\
p & = \text{number of PARTIAL variables} \\
c & = \text{number of components}
\end{align*}
\]
• The minimum allocated memory required is

\[ 232v + 120p + 48c + \max(8cv, 8vp + 4(v + p)(v + p + 1)) \]

bytes
• The time required to compute the correlation matrix is roughly proportional to

\[ n(v + p)^2 + \frac{p}{2}(v + p)(v + p + 1) \]

• The time required to compute eigenvalues is roughly proportional to \( v^3 \).
• The time required to compute eigenvectors is roughly proportional to \( cv^2 \).

Displayed Output

The PRINCOMP procedure displays the following items if the DATA= data set is not
TYPE=CORR, TYPE=COV, TYPE=SSCP, TYPE=UCORR, or TYPE=UCOV:

• Simple Statistics, including the Mean and Std (standard deviation) for each
  variable. If you specify the NOINT option, the uncorrected standard deviation
  (UStD) is displayed.
• the Correlation or, if you specify the COV option, the Covariance Matrix

The PRINCOMP procedure displays the following items if you use the PARTIAL
statement.

• Regression Statistics, giving the \( R \)-square and RMSE (root mean square error)
  for each VAR variable as predicted by the PARTIAL variables (not shown)
• Standardized Regression Coefficients or, if you specify the COV option,
  Regression Coefficients for predicting the VAR variables from the PARTIAL
  variables (not shown)
• the Partial Correlation Matrix or, if you specify the COV option, the Partial
  Covariance Matrix (not shown)

The PRINCOMP procedure displays the following item if you specify the COV op-

• the Total Variance

The PRINCOMP procedure displays the following items unless you specify the
NOPRINT option:

• Eigenvalues of the correlation or covariance matrix, as well as the Difference
  between successive eigenvalues, the Proportion of variance explained by each
  eigenvalue, and the Cumulative proportion of variance explained
• the Eigenvectors
ODS Table Names

PROC PRINCOMP assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

**Table 58.1. ODS Tables Produced in PROC PRINCOMP**

ODS Graphics (Experimental)

This section describes the use of ODS for creating graphics with the PRINCOMP procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

You can specify the N= option in the PRINCOMP statement to control the number of principal components to be displayed.

**ODS Graph Names**

PROC PRINCOMP assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 58.2.
To request these graphs, you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

**Table 58.2.** ODS Graphics Produced by PROC PRINCOMP

**Examples**

**Example 58.1. Temperatures**

This example analyzes mean daily temperatures in selected cities in January and July. Both the raw data and the principal components are plotted to illustrate how principal components are orthogonal rotations of the original variables.

The following statements create the `Temperature` data set:

```plaintext
data Temperature;
  title 'Mean Temperature in January and July for Selected Cities';
  input City $1-15 January July;
  cards;
    Mobile 51.2 81.6
    Phoenix 51.2 91.2
    Little Rock 39.5 81.4
    Sacramento 45.1 75.2
    Denver 29.9 73.0
    Hartford 24.8 72.7
    Wilmington 32.0 75.8
    Washington DC 35.6 78.7
    Jacksonville 54.6 81.0
    Miami 67.2 82.3
    Atlanta 42.4 78.0
    Boise 29.0 74.5
    Chicago 22.9 71.9
    Peoria 23.8 75.1
    Indianapolis 27.9 75.0
    Des Moines 19.4 75.1
    Wichita 31.3 80.7
    Louisville 33.3 76.9
```

* number of variables to be analyzed
New Orleans      52.9  81.9
Portland, ME     21.5  68.0

Cheyenne         26.6  69.1
;

The following statements plot the temperature data set. For information on the %PLOTIT macro, see Appendix B, “Using the %PLOTIT Macro.”

title2 'Plot of Raw Data';
%plotit(data=Temperature,labelvar=City,
   plotvars=July January, color=black, colors=black);
run;
The results are displayed in Output 58.1.1, which shows a scatter diagram of the 64 pairs of data points with July temperatures plotted against January temperatures.

Output 58.1.1. Plot of Raw Data

```
proc princomp data=Temperature cov out=Prin;
var July January;
run;
```

Output 58.1.2 displays the PROC PRINCOMP output. The standard deviation of January (11.712) is higher than the standard deviation of July (5.128). The COV option in the PROC PRINCOMP statement requests the principal components to be computed from the covariance matrix. The total variance is 163.474. The first principal component explains about 94% of the total variance, and the second principal component explains only about 6%. The eigenvalues sum to the total variance.
Note that January receives a higher loading on Prin1 because it has a higher standard deviation than July, and the PRINCOMP procedure calculates the scores using the centered variables rather than the standardized variables.

**Output 58.1.2.** Results of Principal Component Analysis

<table>
<thead>
<tr>

</tbody>
</table>

The following statement plots the Prin data set created from the previous PROC PRINCOMP statement:

```plaintext
title2 'Plot of Principal Components';
%plotit(data=Prin,labelvar=City,
       plotvars=Prin2 Prin1, color=black, colors=black);
run;
```
Output 58.1.3 displays a plot of the second principal component Prin2 against the first principal component Prin1. It is clear from this plot that the principal components are orthogonal rotations of the original variables and that the first principal component has a larger variance than the second principal component. In fact, Prin1 has a larger variance than either of the original variables July and January.

Output 58.1.3. Plot of Principal Components
Example 58.2. Crime Rates

The following data provide crime rates per 100,000 people in seven categories for each of the fifty states in 1977. Since there are seven numeric variables, it is impossible to plot all the variables simultaneously. Principal components can be used to summarize the data in two or three dimensions, and they help to visualize the data. The following statements produce Output 58.2.1:

\begin{verbatim}
data Crime;
  title 'Crime Rates per 100,000 Population by State';
  input State $1-15 Murder Rape Robbery Assault
             Burglary Larceny Auto_Theft;
  cards;
  Alabama 14.2 25.2 96.8 278.3 1135.5 1881.9 280.7

</tbody>
</table>
The eigenvalues indicate that two or three components provide a good summary of the data, two components accounting for 76% of the total variance and three components explaining 87%. Subsequent components contribute less than 5% each.

The first component is a measure of overall crime rate since the first eigenvector shows approximately equal loadings on all variables. The second eigenvector has high positive loadings on variables Auto_Theft and Larceny and high negative loadings on variables Murder and Assault. There is also a small positive loading on Burglary and a small negative loading on Rape. This component seems to measure the preponderance of property crime over violent crime. The interpretation of the third component is not obvious.

A simple way to examine the principal components in more detail is to display the output data set sorted by each of the large components. The following statements produce Output 58.2.2 through Output 58.2.3:

```latex
proc sort data=Crime_Components;
  by Prin1;
run;

proc print;
  id State;
  var Prin1 Prin2 Murder Rape Robbery
       Assault Burglary Larceny Auto_Theft;
  title2 'States Listed in Order of Overall Crime Rate';
  title3 'As Determined by the First Principal Component';
run;

proc sort data=Crime_Components;
  by Prin2;
run;

proc print;
  id State;
  var Prin1 Prin2 Murder Rape Robbery
       Assault Burglary Larceny Auto_Theft;
  title2 'States Listed in Order of Property Vs. Violent Crime';
  title3 'As Determined by the Second Principal Component';
run;
```
Output 58.2.2. OUT= Data Set Sorted by First Principal Component

Another recommended procedure is to make scatter plots of the first few components. The sorted listings help to identify observations on the plots. The following statements produce Output 58.2.4 through Output 58.2.5:

```plaintext
title2 'Plot of the First Two Principal Components';
%plotit(data=Crime_Components,labelvar=State,
   plotvars=Prin2 Prin1, color=black, colors=black);
run;

%plotit(data=Crime_Components,labelvar=State,
   plotvars=Prin3 Prin1, color=black, colors=black);
run;
```

**Output 58.2.4.** Plot of the First Two Principal Components

![Plot of the First Two Principal Components](image-url)
Output 58.2.5. Plot of the First and Third Principal Components

It is possible to identify regional trends on the plot of the first two components. Nevada and California are at the extreme right, with high overall crime rates but an average ratio of property crime to violent crime. North and South Dakota are on the extreme left with low overall crime rates. Southeastern states tend to be in the bottom of the plot, with a higher-than-average ratio of violent crime to property crime. New England states tend to be in the upper part of the plot, with a greater-than-average ratio of property crime to violent crime.

The most striking feature of the plot of the first and third principal components is that Massachusetts and New York are outliers on the third component.

Example 58.3. Basketball Data

The data in this example are rankings of 35 college basketball teams. The rankings were made before the start of the 1985–86 season by 10 news services.

The purpose of the principal component analysis is to compute a single variable that best summarizes all 10 of the preseason rankings.

Note that the various news services rank different numbers of teams, varying from 20 through 30 (there is a missing rank in one of the variables, WashPost). And,
of course, each service does not rank the same teams, so there are missing values in these data. Each of the 35 teams is ranked by at least one news service.

The PRINCOMP procedure omits observations with missing values. To obtain principal component scores for all of the teams, it is necessary to replace the missing values. Since it is the best teams that are ranked, it is not appropriate to replace missing values with the mean of the nonmissing values. Instead, an ad hoc method is used that replaces missing values by the mean of the unassigned ranks. For example, if 20 teams are ranked by a news service, then ranks 21 through 35 are unassigned. The mean of ranks 21 through 35 is 28, so missing values for that variable are replaced by the value 28. To prevent the method of missing-value replacement from having an undue effect on the analysis, each observation is weighted according to the number of nonmissing values it has. See Example 59.3 in Chapter 59, “The PRINQUAL Procedure,” for an alternative analysis of these data.

Since the first principal component accounts for 78% of the variance, there is substantial agreement among the rankings. The eigenvector shows that all the news services are about equally weighted, so a simple average would work almost as well as the first principal component. The following statements produce Output 58.3.1 through Output 58.3.3:

```sas
/*-----------------------------------------------------------*/
/**/
/* Preseason 1985 College Basketball Rankings */
/* (rankings of 35 teams by 10 news services) */

**Example 58.4. PRINCOMP Graphics (Experimental)**

This example illustrates the experimental ODS graphics in PROC PRINCOMP, using the example in the the “Getting Started” section on page 3596.

The following statements request plots in PROC PRINCOMP.
Example 58.4. PRINCOMP Graphics (Experimental)

```sas
ods html;
ods graphics on;

proc princomp data=Jobratings(drop='Overall Rating'n) n=5;
   run;
ods graphics off;
ods html close;
```

These graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the PRINCOMP procedure, see the “ODS Graphics” section on page 3613.

The N= 5 option in the PROC PRINCOMP statement sets the number of principal components to 5.

Output 58.4.1 shows the eigenvalue plots. Each point in the plot on the left shows an eigenvalue; each point in the plot on the right shows the (cumulative) proportion of variance explained by each component.

**Output 58.4.1.** Eigenvalue Scatter Plot (Experimental)

![Eigenvalue Scatter Plot](image)

Output 58.4.2 shows a scatter matrix plot between the first five components. The histogram of each component is displayed in the diagonal element of the matrix.
Output 58.4.2. Component Scores Matrix Plot (Experimental)

Output 58.4.3 shows a component pattern profile. The Y-axis shows the correlation between a component and a variable. There is one profile for each component. Line patterns are used to differentiate correlations between components.

The nearly horizontal profile from the first component indicates that the first component is mostly correlated evenly across all variables. The second component is positively correlated with the variables Observational Skills and Willingness to Confront Problems and is negatively correlated with the variables Interest in People and Interpersonal Sensitivity.
Output 58.4.3. Component Pattern Plot (Experimental)

Output 58.4.4 shows a scatter plot of the first and second components. Observation numbers are used as the plotting symbol.
Output 58.4.4. Component Scores Plot: 1st versus 2nd (Experimental)

Output 58.4.5 shows a scatter plot of the first and third components.
Output 58.4.5. Component Scores Plot: 1st versus 3rd (Experimental)

Output 58.4.6 shows a scatter plot of the second and third components, displaying density with color. Color interpolation is based on the first component, going from blue (or light gray) (minimum density), magenta (or dark gray) (median density), and to red (or black) (maximum density).
Output 58.4.6. Painted Components Scores Plot: 2nd versus 3rd, Painted by 1st (Experimental)

Chapter 59. The PRINQUAL Procedure
Chapter 59
The PRINQUAL Procedure

Overview

The PRINQUAL procedure obtains linear and nonlinear transformations of variables by using the method of alternating least squares to optimize properties of the transformed variables’ covariance or correlation matrix. Nonoptimal transformations for logarithm, rank, exponentiation, inverse sine, and logit are also available with PROC PRINQUAL. Experimental graphics are now available with the PRINQUAL procedure. For more information, see the “ODS Graphics” section on page 3677.

The PRINQUAL (principal components of qualitative data) procedure is a data transformation procedure that is based on the work of Kruskal and Shepard (1974); Young, Takane, and de Leeuw (1978); Young (1981); and Winsberg and Ramsay (1983). You can use PROC PRINQUAL to

- generalize ordinary principal component analysis to a method capable of analyzing data that are not quantitative
- perform metric and nonmetric multidimensional preference (MDPREF) analyses (Carroll 1972)
- preprocess data, transforming variables prior to their use in other data analyses
- summarize mixed quantitative and qualitative data and detect nonlinear relationships
- reduce the number of variables for subsequent use in regression analyses, cluster analyses, and other analyses

The PRINQUAL procedure provides three methods of transforming a set of qualitative and quantitative variables to optimize the transformed variables’ covariance or correlation matrix. These methods are

- maximum total variance (MTV)
- minimum generalized variance (MGV)
- maximum average correlation (MAC)

All three methods attempt to find transformations that decrease the rank of the covariance matrix computed from the transformed variables. Transforming the variables to maximize the variance accounted for by a few linear combinations (using the MTV method) locates the observations in a space with dimensionality that approximates the stated number of linear combinations as much as possible, given the transformation constraints. Transforming the variables to minimize their generalized variance or
maximize the sum of correlations also reduces the dimensionality. The transformed qualitative (nominal and ordinal) variables can be thought of as quantified by the analysis, with the quantification done in the context set by the algorithm. The data are quantified so that the proportion of variance accounted for by a stated number of principal components is locally maximal, the generalized variance of the variables is locally minimal, or the average of the correlations is locally maximal.

The data can contain variables with nominal, ordinal, interval, and ratio scales of measurement (Siegel 1956). Any mix is allowed with all methods. PROC PRINQUAL can

- transform nominal variables by scoring the categories to optimize the covariance matrix (Fisher 1938)
- transform ordinal variables monotonically by scoring the ordered categories so that order is weakly preserved (adjacent categories can be merged) and the covariance matrix is optimized. You can untie ties optimally or leave them tied (Kruskal 1964). You can also transform ordinal variables to ranks.
- transform interval and ratio scale of measurement variables linearly, or transform them nonlinearly with spline transformations (de Boor 1978; van Rijckevorsel 1982) or monotone spline transformations (Winsberg and Ramsay 1983). In addition, nonoptimal transformations for logarithm, exponential, power, logit, and inverse trigonometric sine are available.
- for all transformations, estimate missing data without constraint, with category constraints (missing values within the same group get the same value), and with order constraints (missing value estimates in adjacent groups can be tied to preserve a specified ordering). Refer to Gifi (1990) and Young (1981).

The PROC PRINQUAL iterations produce a set of transformed variables. Each variable’s new scoring satisfies a set of constraints based on the original scoring of the variable and the specified transformation type. First, all variables are required to satisfy transformation standardization constraints; that is, all variables have a fixed mean and variance. The other constraints include linear constraints, weak order constraints, category constraints, and smoothness constraints. The new set of scores is selected from the sets of possible scorings that do not violate the constraints so that the method criterion is locally optimized.

The displayed output from PROC PRINQUAL is a listing of the iteration history. However, the primary output from PROC PRINQUAL is an output data set. By default, the procedure creates an output data set that contains variables with _TYPE_='SCORE'. These observations contain original variables, transformed variables, components, or data approximations. If you specify the CORRELATIONS option in the PROC PRINQUAL statement, the data set also contains observations with _TYPE_='CORR'; these observations contain correlations or component structure information.
The Three Methods of Variable Transformation

The three methods of variable transformation provided by PROC PRINQUAL are discussed in the following sections.

The Maximum Total Variance (MTV) Method

The MTV method (Young, Takane, and de Leeuw 1978) is based on the principal component model, and it attempts to maximize the sum of the first \( r \) eigenvalues of the covariance matrix. This method transforms variables to be (in a least-squares sense) as similar to linear combinations of \( r \) principal component score variables as possible, where \( r \) can be much smaller than the number of variables. This maximizes the total variance of the first \( r \) components (the trace of the covariance matrix of the first \( r \) principal components). Refer to Kuhfeld, Sarle, and Young (1985).

On each iteration, the MTV algorithm alternates classical principal component analysis (Hotelling 1933) with optimal scaling (Young 1981). When all variables are ordinal preference ratings, this corresponds to Carroll’s (1972) MDPREF analysis. You can request the dummy variable initialization method suggested by Tenenhaus and Vachette (1977), who independently proposed the same iterative algorithm for nominal and interval scale-of-measurement variables.

The Minimum Generalized Variance (MGV) Method

The MGV method (Sarle 1984) uses an iterated multiple regression algorithm in an attempt to minimize the determinant of the covariance matrix of the transformed variables. This method transforms each variable to be (in a least-squares sense) as similar to linear combinations of the remaining variables as possible. This locally minimizes the generalized variance of the transformed variables, the determinant of the covariance matrix, the volume of the parallelepiped defined by the transformed variables, and the sphericity (the extent to which a quadratic form in the optimized covariance matrix defines a sphere). Refer to Kuhfeld, Sarle, and Young (1985).

On each iteration for each variable, the MGV algorithm alternates multiple regression with optimal scaling. The multiple regression involves predicting the selected variable from all other variables. You can request a dummy variable initialization using a modification of the Tenenhaus and Vachette (1977) method that is appropriate with a regression algorithm. This method can be viewed as a way of investigating the nature of the linear and nonlinear dependencies in, and the rank of, a data matrix containing variables that can be nonlinearly transformed. This method tries to create a less-than-full-rank data matrix. The matrix contains the transformation of each variable that is most similar to what the other transformed variables predict.

The Maximum Average Correlation (MAC) Method

The MAC method (de Leeuw 1985) uses an iterated constrained multiple regression algorithm in an attempt to maximize the average of the elements of the correlation matrix. This method transforms each variable to be (in a least-squares sense) as similar to the average of the remaining variables as possible.

On each iteration for each variable, the MAC algorithm alternates computing an equally weighted average of the other variables with optimal scaling. The MAC
method is similar to the MGV method in that each variable is scaled to be as similar
to a linear combination of the other variables as possible, given the constraints on
the transformation. However, optimal weights are not computed. You can use the
MAC method when all variables are positively correlated or when no monotonicity
constraints are placed on any transformations. Do not use this method with nega-
tively correlated variables when some optimal transformations are constrained to be
increasing because the signs of the correlations are not taken into account. The MAC
method is useful as an initialization method for the MTV and MGV methods.

Getting Started

In the following example, PROC PRINQUAL uses the MTV method. Suppose that
the problem is to linearize a curve through three-dimensional space. Let

\[
X_1 = X^3 \\
X_2 = X_1 - X^5 \\
X_3 = X_2 - X^6
\]

where \( X = -1.00, -0.98, -0.96, \ldots, 1.00 \).

These three variables define a curve in three-dimensional space. The GPLOT pro-
cEDURE is used to display two-dimensional views of this curve. These data are com-
pletely described by three linear components, but they define a single curve, which
could be described as a single nonlinear component.

PROC PRINQUAL is used to attempt to straighten the curve into a one-dimensional
line with a continuous transformation of each variable. The N=1 option in the PROC
PRINQUAL statement requests one principal component. The TRANSMFORM state-
ment requests a cubic spline transformation with nine knots. Splines are curves,
which are usually required to be continuous and smooth. Splines are usually de-
\n
One component accounts for 71 percent of the variance of the untransformed data,
and after 45 iterations, over 98 percent of the variance of the transformed data is
accounted for by one component (see Figure 59.2). Note that the algorithm would
not have converged with 50 iterations and the default convergence criterion, so more
iterations may be needed for this problem.

PROC PRINQUAL creates an output data set (which is not displayed) that contains
both the original and transformed variables. The original variables have the names
$X_1$, $X_2$, and $X_3$. Transformed variables are named $TX_1$, $TX_2$, and $TX_3$. All observ-
vations in the output data set have _TYPE_ = ‘SCORE’, since the CORRELATIONS
option is not specified in the PROC PRINQUAL statement. The GPLOT procedure
uses this output data set and displays the nonlinear transformations of all three vari-
ables and the nearly one-dimensional scatter plot (see Figure 59.3 and Figure 59.4).

PROC PRINQUAL tries to project each variable on the first principal component.
Notice that the curve in this example is closer to a circle than to a function from some
views (see the plot of $X_3$ vs. $X_2$ in Figure 59.1) and that the first component does
not run approximately from one end point of the curve to the other (see Figure 59.4).
Since the curve has these characteristics, PROC PRINQUAL linearizes the scatter
plot by collapsing the scatter around the principal axis, not by straightening the curve
into a single line. PROC PRINQUAL would straighten simpler curves.

The following statements produce Figure 59.1 through Figure 59.4:

```sas
* Generate a Three-Dimensional Curve;
data X;
do X = -1 to 1 by 0.02;
   X1 = X ** 3;
   X2 = X1 - X ** 5;
   X3 = X2 - X ** 6;
   output;
end;
drop X;
run;

go2 options goutmode=replace nodisplay;
%let opts = haxis=axis2 vaxis=axis1 frame cframe=ligr;
* Depending on your goptions, these plot options may work better:
* %let opts = haxis=axis2 vaxis=axis1 frame;
proc gplot data=X;
title;
axis1 minor=none label=(angle=90 rotate=0)
   order=( -1 to 1);
axis2 minor=none order=( -1 to 1);
plot X1*X2 / &opts name='prqin1';
plot X3*X2 / &opts name='prqin2' vreverse;
plot X1*X3 / &opts name='prqin3';
symbol1 color=blue;
run; quit;
go2 options display;
proc greplay nofs tc=sashelp.templt template=l2r2;
   igcut gseg;
   treplay 1:prqin1 2:prqin2 3:prqin3;
run; quit;
```
* Try to Straighten the Curve;
proc prinqual data=X n=1 maxiter=50 covariance converge=0.007;
  title 'Iteratively Derive Variable Transformations';
  transform spline(X1-X3 / nknots=9);
run;

* Plot the Transformations;
goptions nodisplay;
proc gplot;
  title;
  axis1 minor=none label=(angle=90 rotate=0);
  axis2 minor=none;
  plot TX1*X1 / &opts name='prqin4';
  plot TX2*X2 / &opts name='prqin5';
  plot TX3*X3 / &opts name='prqin6';
  symbol1 color=blue;
run; quit;

goptions display;
proc greplay nofs tc=sashelp.templt template=l2r2;
  igout gseg;
  treplay 1:prqin4 2:prqin6 3:prqin5;
run; quit;

* Plot the Straightened Scatter Plot;
goptions nodisplay;
proc gplot;
  axis1 minor=none label=(angle=90 rotate=0)
    order=(-1 to 1);
  axis2 minor=none order=(-1 to 1);

Figure 59.2. PROC PRINQUAL MTV Iteration History
Figure 59.3. Variable Transformation Plots
Figure 59.4. Plots of the Nearly One-Dimensional Curve
Syntax

The following statements are available in PROC PRINQUAL.

PROC PRINQUAL < options > ;
  TRANSFORM transform(variables < / t-options >)
      < ... transform(variables < / t-options >) > ;
  BY variables ;
  FREQ variable ;
  ID variables ;
  WEIGHT variable ;

To use PROC PRINQUAL, you need the PROC PRINQUAL and TRANSFORM statements. You can abbreviate all options and t-options to their first three letters. This is a special feature of PROC PRINQUAL and is not generally true of other SAS/STAT procedures.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC PRINQUAL statement. The remaining statements are described in alphabetical order.

PROC PRINQUAL Statement

PROC PRINQUAL < options > ;

The PROC PRINQUAL statement starts the PRINQUAL procedure. Optionally, this statement identifies an input data set, creates an output data set, specifies the algorithm and other computational details, and controls displayed output. The following table summarizes options available in the PROC PRINQUAL statement.
### The PRINQUAL Procedure

**Chapter 59. The PRINQUAL Procedure**

<table>
<thead>
<tr>
<th>Task</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identify input data set</td>
<td>specifies input SAS data set <strong>DATA=</strong></td>
</tr>
</tbody>
</table>
| **Specify details for output data set** | outputs approximations to transformed variables **APPROXIMATIONS**

specifies number of MGV models before refreshing **REFRESH=**  
restarts iterations **REITERATE**  
specifies singularity criterion **SINGULAR=**  
specifies input observation type **TYPE=** |
| **Control the number of iterations** | specifies minimum criterion change **CCONVERGE=**  
specifies number of first iteration to be displayed **CHANGE=**  
specifies minimum data change **CONVERGE=**  
specifies number of MAC initialization iterations **INITITER=**  
specifies maximum number of iterations **MAXITER=** |
| **Specify details for handling missing values** | includes monotone special missing values **MONOTONE=**  
excludes observations with missing values **NOMISS**  
unties special missing values **UNTIE=** |
| **Suppress displayed output** | suppresses displayed output **NOPRINT** |

The following list describes these options in alphabetical order.

**APREFIX=name**

**APR=name**

specifies a prefix for naming the approximation variables. By default, APREFIX=A. Specifying the APREFIX= option also implies the APPROXIMATIONS option.
APPROXIMATIONS
APPROX
APP
includes principal component approximations to the transformed variables (Eckart and Young 1936) in the output data set. Variable names are constructed from the value of the APREFIX= option and the input variable names. If you specify the APREFIX= option, then approximations are automatically included. If you specify the APPROXIMATIONS option and not the APREFIX= option, then the APPROXIMATIONS option uses the default, APREFIX=A, to construct the variable names.

CCONVERGE=n
CCO=n
specifies the minimum change in the criterion being optimized that is required to continue iterating. By default, CCONVERGE=0.0. The CCONVERGE= option is ignored for METHOD=MAC. For the MGV method, specify CCONVERGE=-2 to ensure data convergence.

CHANGE=n
CHA=n
specifies the number of the first iteration to be displayed in the iteration history table. The default is CHANGE=1. When you specify a larger value for n, the first n – 1 iterations are not displayed, thus speeding up the analysis. The CHANGE= option is most useful with the MGV method, which is much slower than the other methods.

CONVERGE=n
CON=n
specifies the minimum average absolute change in standardized variable scores that is required to continue iterating. By default, CONVERGE=0.00001. Average change is computed over only those variables that can be transformed by the iterations, that is, all LINEAR, OPSCORE, MONOTONE, UNTIE, SPLINE, MSPLINE, and SSPLINE variables and nonoptimal transformation variables with missing values. For more information, see the section “Optimal Transformations” on page 3662.

COVARIANCE
COV
computes the principal components from the covariance matrix. The variables are always centered to mean zero. If you do not specify the COVARIANCE option, the variables are also standardized to variance one, which means the analysis is based on the correlation matrix.

CORRELATIONS
COR
includes correlations and the component structure matrix in the output data set. By default, this information is not included.

DATA=SAS-data-set
specifies the SAS data set to be analyzed. The data set must be an ordinary SAS data set; it cannot be a TYPE=CORR or TYPE=COV data set. If you omit the DATA= option, the PRINQUAL procedure uses the most recently created SAS data set.
DUMMY
DUM

expands variables specified for OPSCORE optimal transformations to dummy variables for the initialization (Tenenhaus and Vachette 1977). By default, the initial values of OPSCORE variables are the actual data values. The dummy variable nominal initialization requires considerable time and memory, so it might not be possible to use the DUMMY option with large data sets. No separate report of the initialization is produced. Initialization results are incorporated into the first iteration displayed in the iteration history table. For details, see the section “Optimal Transformations” on page 3662.

INITITER=n
INI=n

specifies the number of MAC iterations required to initialize the data before starting MTV or MGV iterations. By default, INITITER=0. The INITITER= option is ignored if METHOD=MAC.

MAXITER=n
MAX=n

specifies the maximum number of iterations. By default, MAXITER=30.

MDPREF
MDP

specifies a multidimensional preference analysis by implying the STANDARD, SCORES, and CORRELATIONS options. This option also suppresses warnings when there are more variables than observations.

METHOD=MAC | MGV | MTV
MET=MAC | MGV | MTV

specifies the optimization method. By default, METHOD=MTV. Values of the METHOD= option are MTV for maximum total variance, MGV for minimum generalized variance, or MAC for maximum average correlation. You can use the MAC method when all variables are positively correlated or when no monotonicity constraints are placed on any transformations. See the section “The Three Methods of Variable Transformation” on page 3643.

MONOTONE=two-letters
MON=two-letters

specifies the first and last special missing value in the list of those special missing values to be estimated using within-variable order and category constraints. By default, there are no order constraints on missing value estimates. The two-letters value must consist of two letters in alphabetical order. For example, MONOTONE=DF means that the estimate of .D must be less than or equal to the estimate of .E, which must be less than or equal to the estimate of .F; no order constraints are placed on estimates of _, .A through .C, and .G through .Z. For details, see the “Missing Values” section on page 3667, and “Optimal Scaling” in Chapter 75, “The TRANSREG Procedure.”
N=n
   specifies the number of principal components to be computed. By default, N=2.

NOCHECK
NOC
   turns off computationally intensive numerical error checking for the MGV method. If you do not specify the NOCHECK option, the procedure computes $R^2$ from the squared length of the predicted values vector and compares this value to the $R^2$ computed from the error sum of squares that is a by-product of the sweep algorithm (Goodnight 1978). If the two values of $R^2$ differ by more than the square root of the value of the SINGULAR= option, a warning is displayed, the value of the REFRESH= option is halved, and the model is refit after refreshing. Specifying the NOCHECK option slightly speeds up the algorithm. Note that other less computationally intensive error checking is always performed.

NOMISS
NOM
   excludes all observations with missing values from the analysis, but does not exclude them from the OUT= data set. If you omit the NOMISS option, PROC PRINQUAL simultaneously computes the optimal transformations of the nonmissing values and estimates the missing values that minimize squared error.

   Casewise deletion of observations with missing values occurs when you specify the NOMISS option, when there are missing values in IDENTITY variables, when there are weights less than or equal to 0, or when there are frequencies less than 1. Excluded observations are output with a blank value for the _TYPE_ variable, and they have a weight of 0. They do not contribute to the analysis but are scored and transformed as supplementary or passive observations. See the “Passive Observations” section on page 3674 and the “Missing Values” section on page 3667 for more information on excluded observations and missing data.

NOPRINT
NOP
   suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

OUT=SAS-data-set
   specifies an output SAS data set that contains results of the analysis. If you omit the OUT= option, PROC PRINQUAL still creates an output data set and names it using the DATAn convention. If you want to create a permanent SAS data set, you must specify a two-level name. (Refer to the discussion in SAS Language Reference: Concepts.) You can use the REPLACE, APPROXIMATIONS, SCORES, and CORRELATIONS options to control what information is included in the output data set. For details, see the “Output Data Set” section on page 3669.

PREFIX=name
PRE=name
   specifies a prefix for naming the principal components. By default, PREFIX=Prin. As a result, the principal component default names are Prin1, Prin2, . . . , Prin n.
REFRESH=n
REF=n
specifies the number of variables to scale in the MGV method before computing a new inverse. By default, REFRESH=5. PROC PRINQUAL uses the REFRESH= option in the sweep algorithm of the MGV method. Large values for the REFRESH= option make the method run faster but with increased error. Small values make the method run more slowly and with more numerical accuracy.

REITERATE
REI
enables the PRINQUAL procedure to use previous transformations as starting points. The REITERATE option affects only variables that are iteratively transformed (specified as LINEAR, SPLINE, MSPLINE, SSPLINE, UNTIE, OPSCORE, and MONOTONE). For iterative transformations, the REITERATE option requests a search in the input data set for a variable that consists of the value of the TPREFIX= option followed by the original variable name. If such a variable is found, it is used to provide the initial values for the first iteration. The final transformation is a member of the transformation family defined by the original variable, not the transformation family defined by the initialization variable. See the “REITERATE Option Usage” section on page 3673.

REPLACE
REP
replaces the original data with the transformed data in the output data set. The names of the transformed variables in the output data set correspond to the names of the original variables in the input data set. If you do not specify the REPLACE option, both original variables and transformed variables (with names constructed from the TPREFIX= option and the original variable names) are included in the output data set.

SCORES
SCO
includes principal component scores in the output data set. By default, scores are not included.

SINGULAR=n
SIN=n
specifies the largest value within rounding error of zero. By default, SINGULAR=1E-8. The PRINQUAL procedure uses the value of the SINGULAR= option for checking \((1 - R^2)\) when constructing full-rank matrices of predictor variables, checking denominators before dividing, and so on.

STANDARD
STD
standardizes the principal component scores in the output data set to mean zero and variance one instead of the default mean zero and variance equal to the corresponding eigenvalue. See the SCORES option.
TPREFIX=\textit{name}

TPR=\textit{name}

specifies a prefix for naming the transformed variables. By default, TPREFIX=T. The TPREFIX= option is ignored if you specify the REPLACE option.

TSTANDARD=\textit{CENTER} | \textit{NOMISS} | \textit{ORIGINAL} | \textit{Z}

TST=\textit{CEN} | \textit{NOM} | \textit{ORI} | \textit{Z}

specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When the TSTANDARD= option is specified in the PROC statement, it specifies the default standardization for all variables. When you specify TSTANDARD= as a t-option, it overrides the default standardization just for selected variables.

\begin{itemize}
  \item \textbf{CENTER} centers the output variables to mean zero, but the variances are the same as the variances of the input variables.
  \item \textbf{NOMISS} sets the means and variances of the transformed variables in the OUT= data set, computed over all output values that correspond to nonmissing values in the input data set, to the means and variances computed from the nonmissing observations of the original variables. The TSTANDARD=NOMISS specification is useful with missing data. When a variable is linearly transformed, the final variable contains the original nonmissing values and the missing value estimates. In other words, the nonmissing values are unchanged. If your data have no missing values, TSTANDARD=NOMISS and TSTANDARD=ORIGINAL produce the same results.
  \item \textbf{ORIGINAL} sets the means and variances of the transformed variables to the means and variances of the original variables. This is the default.
  \item \textbf{Z} standardizes the variables to mean zero, variance one.
\end{itemize}

For nonoptimal variable transformations, the means and variances of the original variables are actually the means and variances of the nonlinearly transformed variables, unless you specify the ORIGINAL nonoptimal t-option in the TRANSFORM statement. For example, if a variable \textit{X} with no missing values is specified as LOG, then, by default, the final transformation of \textit{X} is simply LOG(\textit{X}), not LOG(\textit{X}) standardized to the mean of \textit{X} and variance of \textit{X}.

\texttt{TYPE='text'|name}

\texttt{TYP='text'|name}

specifies the valid value for the \_TYPE\_ variable in the input data set. If PROC PRINQUAL finds an input \_TYPE\_ variable, it uses only observations with a \_TYPE\_ value that matches the TYPE= value. This enables a PROC PRINQUAL OUT= data set containing correlations to be used as input to PROC PRINQUAL without requiring a WHERE statement to exclude the correlations. If a \_TYPE\_ variable is not in the data set, all observations are used. The default is TYPE='SCORE', so if you do not specify the TYPE= option, only observations with \_TYPE\_ = 'SCORE' are used.
PROC PRINQUAL displays a note when it reads observations with blank values of \_TYPE\_, but it does not automatically exclude those observations. Data sets created by the TRANSREG and PRINQUAL procedures have blank \_TYPE\_ values for those observations that were excluded from the analysis due to nonpositive weights, nonpositive frequencies, or missing data. When these observations are read again, they are excluded for the same reason that they were excluded from their original analysis, not because their \_TYPE\_ value is blank.

\textbf{UNTIE=two-letters}
\textbf{UNT=two-letters}

specifies the first and last special missing value in the list of those special missing values that are to be estimated with within-variable order constraints but no category constraints. The \textit{two-letters} value must consist of two letters in alphabetical order. By default, there are category constraints but no order constraints on special missing value estimates. For details, see the “Missing Values” section on page 3667. Also, see “Optimal Scaling” in Chapter 75, “The TRANSREG Procedure.”

**BY Statement**

```sas
BY variables ;
```

You can specify a BY statement with PROC PRINQUAL to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement options NOTSORTED or DESCENDING in the BY statement for the PRINQUAL procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in \textit{SAS Language Reference: Concepts}. For more information on the DATASETS procedure, refer to the discussion in the \textit{SAS Procedures Guide}.

**FREQ Statement**

```sas
FREQ variable ;
```

If one variable in the input data set represents the frequency of occurrence for other values in the observation, list the variable’s name in a FREQ statement. PROC PRINQUAL then treats the data set as if each observation appeared \(n\) times, where \(n\) is the value of the FREQ variable for the observation. Noninteger values of the
FREQ variable are truncated to the largest integer less than the FREQ value. The observation is used in the analysis only if the value of the FREQ statement variable is greater than or equal to 1.

**ID Statement**

```plaintext
ID variables ;
```

The ID statement includes additional character or numeric variables in the output data set. The variables must be contained in the input data set.

**TRANSFORM Statement**

```plaintext
TRANSFORM transform(variables < / t-options >) < . . . transform(variables < / t-options >) > ;
```

The TRANSFORM statement lists the variables to be analyzed (variables) and specifies the transformation (transform) to apply to each variable listed. You must specify a transformation for each variable list in the TRANSFORM statement. The variables are variables in the data set. The t-options are transformation options that provide details for the transformation; these depend on the transform chosen. The t-options are listed after a slash in the parentheses that enclose the variables.

For example, the following statements find a quadratic polynomial transformation of all variables in the data set:

```plaintext
proc prinqual;
   transform spline(_all_ / degree=2);
run;
```

Or, if N1 through N10 are nominal variables and M1 through M10 are ordinal variables, you can use the following statements.

```plaintext
proc prinqual;
   transform opscore(N1-N10) monotone(M1-M10);
run;
```

The following sections describe the transformations available (specified with transform) and the options available for some of the transformations (specified with t-options).

**Families of Transformations**

There are three types of transformation families: nonoptimal, optimal, and other. Each family is summarized as follows.

Nonoptimal transformations preprocess the specified variables, replacing each one with a single new nonoptimal, nonlinear transformation.
Optimal transformations replace the specified variables with new, iteratively derived optimal transformation variables that fit the specified model better than the original variable (except for contrived cases where the transformation fits the model exactly as well as the original variable).

Other transformations are the IDENTITY and SSPLINE transformations. These do not fit into either of the preceding categories.

The following table summarizes the transformations in each family.

<table>
<thead>
<tr>
<th>Family</th>
<th>Members of Family</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Other transformations</td>
<td></td>
</tr>
<tr>
<td>identity, no transformation</td>
<td>IDENTITY</td>
</tr>
<tr>
<td>iterative smoothing spline</td>
<td>SSPLINE</td>
</tr>
</tbody>
</table>

The transform is followed by a variable (or list of variables) enclosed in parentheses. Optionally, depending on the transform, the parentheses can also contain t-options, which follow the variables and a slash. For example,

```
transform log(X Y);
```

computes the LOG transformation of X and Y. A more complex example is

```
transform spline(Y / nknots=2) log(X1 X2 X3);
```

The preceding statement uses the SPLINE transformation of the variable Y and the LOG transformation of the variables X1, X2, and X3. In addition, it uses the NKNOTS= option with the SPLINE transformation and specifies two knots.

The rest of this section provides syntax details for members of the three families of transformations. The t-options are discussed in the section “Transformation Options (t-options)” on page 3663.
Nonoptimal Transformations

Nonoptimal transformations are computed before the iterative algorithm begins. Nonoptimal transformations create a single new transformed variable that replaces the original variable. The new variable is not transformed by the subsequent iterative algorithms (except for a possible linear transformation and missing value estimation).

The following list provides syntax and details for nonoptimal variable transformations.

ARSIN

finds an inverse trigonometric sine transformation. Variables following ARSIN must be numeric, in the interval \((-1.0 \leq X \leq 1.0)\), and they are typically continuous.

EXP

exponentiates variables (the variable $X$ is transformed to $a^X$). To specify the value of $a$, use the PARAMETER= $t$-option. By default, $a$ is the mathematical constant $e = 2.718\ldots$. Variables following EXP must be numeric, and they are typically continuous.

LOG

transforms variables to logarithms (the variable $X$ is transformed to $\log_a(X)$). To specify the base of the logarithm, use the PARAMETER= $t$-option. The default is a natural logarithm with base $e = 2.718\ldots$. Variables following LOG must be numeric and positive, and they are typically continuous.

LOGIT

finds a logit transformation on the variables. The logit of $X$ is $\log(X/(1-X))$. Unlike other transformations, LOGIT does not have a three-letter abbreviation. Variables following LOGIT must be numeric, in the interval $(0.0 < X < 1.0)$, and they are typically continuous.

POWER

raises variables to a specified power (the variable $X$ is transformed to $X^a$). You must specify the power parameter $a$ by specifying the PARAMETER= $t$-option following the variables:

$$ \text{power(variable / parameter=number)} $$

You can use POWER for squaring variables (PARAMETER=2), reciprocal transformations (PARAMETER=−1), square roots (PARAMETER=0.5), and so on. Variables following POWER must be numeric, and they are typically continuous.

RANK

transforms variables to ranks. Ranks are averaged within ties. The smallest input value is assigned the smallest rank. Variables following RANK must be numeric.
**Optimal Transformations**

Optimal transformations are iteratively derived. Missing values for these types of variables can be optimally estimated (see the “Missing Values” section on page 3667).

The following list provides syntax and details for optimal transformations.

**LINEAR**

LIN finds an optimal linear transformation of each variable. For variables with no missing values, the transformed variable is the same as the original variable. For variables with missing values, the transformed nonmissing values have a different scale and origin than the original values. Variables following LINEAR must be numeric.

**MONOTONE**

MON finds a monotonic transformation of each variable, with the restriction that ties are preserved. The Kruskal (1964) secondary least-squares monotonic transformation is used. This transformation weakly preserves order and category membership (ties). Variables following MONOTONE must be numeric, and they are typically discrete.

**MSPLINE**

MSP finds a monotonically increasing B-spline transformation with monotonic coefficients (de Boor 1978; de Leeuw 1986) of each variable. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY t-options with MSPLINE. By default, PROC PRINQUAL uses a quadratic spline. Variables following MSPLINE must be numeric, and they are typically continuous.

**OPSCORE**

OPS finds an optimal scoring of each variable. The OPSCORE transformation assigns scores to each class (level) of the variable. Fisher’s (1938) optimal scoring method is used. Variables following OPSCORE can be either character or numeric; numeric variables should be discrete.

**SPLINE**

SPL finds a B-spline transformation (de Boor 1978) of each variable. By default, PROC PRINQUAL uses a cubic polynomial transformation. You can specify the DEGREE=, KNOTS=, NKNOTS=, and EVENLY t-options with SPLINE. Variables following SPLINE must be numeric, and they are typically continuous.

**UNTIE**

UNT finds a monotonic transformation of each variable without the restriction that ties are preserved. The PRINQUAL procedure uses the Kruskal (1964) primary least-squares monotonic transformation method. This transformation weakly preserves order but not category membership (it may untie some previously tied values). Variables following UNTIE must be numeric, and they are typically discrete.
Other Transformations

IDENTITY
IDE
specifies variables that are not changed by the iterations. The IDENTITY transformation is used for variables when no transformation and no missing data estimation are desired. However, the REFLECT, ADDITIVE, TSTANDARD=Z, and TSTANDARD=CENTER options can linearly transform all variables, including IDENTITY variables, after the iterations. Observations with missing values in IDENTITY variables are excluded from the analysis, and no optimal scores are computed for missing values in IDENTITY variables. Variables following IDENTITY must be numeric.

SSPLINE
SSP
finds an iterative smoothing spline transformation of each variable. The SSPLINE transformation does not generally minimize squared error. You can specify the smoothing parameter with either the SM= t-option or the PARAMETER= t-option. The default smoothing parameter is SM=0. Variables following SSPLINE must be numeric, and they are typically continuous.

Transformation Options (t-options)
If you use a nonoptimal, optimal or other transformation, you can use t-options, which specify additional details of the transformation. The t-options are specified within the parentheses that enclose variables and are listed after a slash. For example,

```
proc prinqual;
   transform spline(X Y / nknots=3);
run;
```

The preceding statements find an optimal variable transformation (SPLINE) of the variables X and Y and use a t-option to specify the number of knots (NKNOTS=). The following is a more complex example.

```
proc prinqual;
   transform spline(Y / nknots=3) spline(X1 X2 / nknots=6);
run;
```

These statements use the SPLINE transformation for all three variables and use t-options as well; the NKNOTS= option specifies the number of knots for the spline.

The following sections discuss the t-options available for nonoptimal, optimal, and other transformations.

The following table summarizes the t-options.

#### Nonoptimal Transformation t-options

**ORIGINAL**

**ORI**

matches the variable’s final mean and variance to the mean and variance of the original variable. By default, the mean and variance are based on the transformed values. The ORIGINAL t-option is available for all of the nonoptimal transformations.

#### Parameter t-options

**PARAMETER=** *number*

**PAR=** *number*

specifies the transformation parameter. The PARAMETER= t-option is available for the EXP, LOG, POWER, SMOOTH, and SSPLINE transformations. For EXP, the parameter is the value to be exponentiated; for LOG, the parameter is the base value; and for POWER, the parameter is the power. For SMOOTH and SSPLINE, the parameter is the raw smoothing parameter. (You can specify a SAS/GRAPH-style smoothing parameter with the SM= t-option.) The default for the PARAMETER= t-option for the LOG and EXP transformations is \( e = 2.718 \ldots \). The default parameter for SSPLINE is computed from SM=0. For the POWER transformation, you must specify the PARAMETER= t-option; there is no default.

**SM=** *n*

specifies a SAS/GRAPH-style smoothing parameter in the range 0 to 100. You can specify the SM= t-option only with the SSPLINE transformation. The smoothness of the function increases as the value of the smoothing parameter increases. By default, SM=0.
Spline t-options

The following t-options are available with the SPLINE and MSPLINE optimal transformations.

**DEGREE=n**
**DEG=n**
specifies the degree of the B-spline transformation. The degree must be a nonnegative integer. The defaults are DEGREE=3 for SPLINE variables and DEGREE=2 for MSPLINE variables.

The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

**EVENLY**
**EVE**
is used with the NKNOTS=t-option to space the knots evenly. The differences between adjacent knots are constant. If you specify NKNOTS=k, k knots are created at

$$\text{minimum} + i((\text{maximum} - \text{minimum})/(k + 1))$$

for \(i = 1, \ldots, k\). For example, if you specify

```plaintext
spline(X / knots=2 evenly)
```

and the variable X has a minimum of 4 and a maximum of 10, then the two interior knots are 6 and 8. Without the EVENLY t-option, the NKNOTS=t-option places knots at percentiles, so the knots are not evenly spaced.

**KNOTS=number-list | n TO m BY p**
**KNO=number-list | n TO m BY p**
specifies the interior knots or break points. By default, there are no knots. The first time you specify a value in the knot list, it indicates a discontinuity in the \(n\)th (from DEGREE=n) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the \((n - 1)\)th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS=t-option with the NKNOTS=t-option. You should keep the number of knots small (see the section “Specifying the Number of Knots” on page 4613 in Chapter 75, “The TRANSREG Procedure.”).

**NKNOTS=n**
**NKN=n**
creates \(n\) knots, the first at the \(100/(n + 1)\) percentile, the second at the \(200/(n + 1)\) percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the twenty-fifth percentile, the median, and the seventy-fifth percentile. By default, NKNOTS=0. The NKNOTS=t-option must be \(\geq 0\).
You cannot use the NKNOTS= \textit{t-option} with the KNOTS= \textit{t-option}. You should keep the number of knots small (see the section “Specifying the Number of Knots” on page 4613 in Chapter 75, “The TRANSREG Procedure,”).

### Other \textit{t}-options

The following \textit{t-options} are available for all transformations.

**NAME=(\textit{variable-list})**  
**NAM=(\textit{variable-list})**
renames variables as they are used in the TRANSFORM statement. This option allows a variable to be used more than once. For example, if the variable \( X \) is a character variable, then the following step stores both the original character variable \( X \) and a numeric variable \( XC \) that contains category numbers in the output data set.

```plaintext
proc prinqual data=A n=1 out=B;  
  transform linear(Y) opscore(X / name=(XC));  
  id X;  
run;
```

**REFLECT**  
**REF**
reflects the transformation

\[ y = -(y - \bar{y}) + \bar{y} \]

after the iterations are completed and before the final standardization and results calculations.

**TSTANDARD=CENTER \ | \ NOMISS \ | \ ORIGINAL \ | \ Z**  
**TST=CEN \ | \ NOM \ | \ ORI \ | \ Z**
specifies the standardization of the transformed variables in the OUT= data set. By default, TSTANDARD=ORIGINAL. When the TSTANDARD= option is specified in the PROC PRINQUAL statement, it specifies the default standardization for all variables. When you specify TSTANDARD= as a \textit{t-option}, it overrides the default standardization just for selected variables.

### WEIGHT Statement

**WEIGHT \ \textit{variable} ;**

When you use a WEIGHT statement, a weighted residual sum of squares is minimized. The WEIGHT statement has no effect on degrees of freedom or number of observations, but the weights affect most other calculations. The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than 0.
Details

Missing Values

PROC PRINQUAL can estimate missing values, subject to optional constraints, so that the covariance matrix is optimized. The procedure provides several approaches for handling missing data. When you specify the NOMISS option in the PROC PRINQUAL statement, observations with missing values are excluded from the analysis. Otherwise, missing data are estimated, using variable means as initial estimates. Missing values for OPSCORE character variables are treated the same as any other category during the initialization. See the section “Missing Values” on page 4599 in Chapter 75, “The TRANSREG Procedure,” for more information on missing data estimation.

Controlling the Number of Iterations

Several options in the PROC PRINQUAL statement control the number of iterations performed. Iteration terminates when any one of the following conditions is satisfied:

- The number of iterations equals the value of the MAXITER= option.
- The average absolute change in variable scores from one iteration to the next is less than the value of the CONVERGE= option.
- The criterion change is less than the value of the CCONVERGE= option.

With the MTV method, the change in the proportion of variance criterion can become negative when the data have converged so that it is numerically impossible, within machine precision, to increase the criterion. Because the MTV algorithm is convergent, a negative criterion change is the result of very small amounts of rounding error. The MGV method displays the average squared multiple correlation (which is not the criterion being optimized), so the criterion change can become negative well before convergence. The MAC method criterion (average correlation) is never computed, so the CCONVERGE= option is ignored for METHOD=MAC. You can specify a negative value for either convergence option if you want to define convergence only in terms of the other convergence option.

With the MGV method, iterations minimize the generalized variance (determinant), but the generalized variance is not reported for two reasons. First, in most data sets, the generalized variance is almost always near zero (or will be after one or two iterations), which is its minimum. This does not mean that iteration is complete; it simply means that at least one multiple correlation is at or near one. The algorithm continues minimizing the determinant in \((m - 1), (m - 2)\) dimensions, and so on. Because the generalized variance is almost always near zero, it does not provide a good indication of how the iterations are progressing. The mean \(R^2\) provides a better indication of convergence. The second reason for not reporting the generalized variance is that almost no additional time is required to compute \(R^2\) values for each step. This is because the error sum of squares is a by-product of the algorithm at each step.
Computing the determinant at the end of each iteration adds more computations to an already computationally intensive algorithm.

You can increase the number of iterations to ensure convergence by increasing the value of the MAXITER= option and decreasing the value of the CONVERGE= option. Because the average absolute change in standardized variable scores seldom decreases below $10^{-11}$, you typically do not specify a value for the CONVERGE= option less than $10^{-8}$ or $10^{-10}$. Most of the data changes occur during the first few iterations, but the data can still change after 50 or even 100 iterations. You can try different combinations of values for the CONVERGE= and MAXITER= options to ensure convergence without extreme overiteration. If the data do not converge with the default specifications, specify the REITERATE option, or try CONVERGE=$10^{-8}$ and MAXITER=50, or CONVERGE=$10^{-10}$ and MAXITER=200.

**Performing a Principal Component Analysis of Transformed Data**

PROC PRINQUAL produces an iteration history table that displays (for each iteration) the iteration number, the maximum and average absolute change in standardized variable scores computed over the iteratively transformed variables, the criterion being optimized, and the criterion change. In order to examine the results of the analysis in more detail, you can analyze the information in the output data set using other SAS procedures.

Specifically, use the PRINCOMP procedure to perform a components analysis on the transformed data. PROC PRINCOMP accepts the raw data from PROC PRINQUAL but issues a warning because the PROC PRINQUAL output data set has _NAME_ and _TYPE_ variables, but it is not a TYPE=CORR data set. You can ignore this warning.

If the output data set contains both scores and correlations, you must subset it for analysis with PROC PRINCOMP. Otherwise, the correlation observations are treated as ordinary observations and the PROC PRINCOMP results are incorrect. For example, consider the following statements:

```sas
proc prinqual data=a out=b correlations replace;
   transform spline(var1-var50 / nknots=3);
run;

proc princomp data=b;
   where _TYPE_='SCORE';
run;
```

Also note that the proportion of variance accounted for, as reported by PROC PRINCOMP, can exceed the proportion of variance accounted for in the last PROC PRINQUAL iteration. This is because PROC PRINQUAL reports the variance accounted for by the components analysis that generated the current scaling of the data, not a components analysis of the current scaling of the data.
Using the MAC Method

You can use the MAC algorithm alone by specifying METHOD=MAC, or you can use it as an initialization algorithm for METHOD=MTV and METHOD=MGV analyses by specifying the iteration option INITITER=. If any variables are negatively correlated, do not use the MAC algorithm with monotonic transformations (MONOTONE, UNTIE, and MSPLINE) because the signs of the correlations among the variables are not used when computing variable approximations. If an approximation is negatively correlated with the original variable, monotone constraints would make the optimally scaled variable a constant, which is not allowed (see the section “Avoiding Constant Transformations” on page 3672). When used with other transformations, the MAC algorithm can reverse the scoring of the variables. So, for example, if variable X is designated LOG(X) with METHOD=MAC and TSTANDARD=ORIGINAL, the final transformation (for example, TX) may not be LOG(X). If TX is not LOG(X), it has the same mean as LOG(X) and the same variance as LOG(X), and it is perfectly negatively correlated with LOG(X). PROC PRINQUAL displays a note for every variable that is reversed in this manner.

You can use the METHOD=MAC algorithm to reverse the scorings of some rating variables before a factor analysis. The correlations among bipolar ratings such as 'like - dislike', 'hot - cold', and 'fragile - monumental' are typically both positive and negative. If some items are reversed to say 'dislike - like', 'cold - hot', and 'monumental - fragile', some of the negative signs can be eliminated, and the factor pattern matrix would be cleaner. You can use PROC PRINQUAL with METHOD=MAC and LINEAR transformations to reverse some items, maximizing the average of the intercorrelations.

Output Data Set

The PRINQUAL procedure produces an output data set by default. By specifying the OUT=, APPROXIMATIONS, SCORES, REPLACE, and CORRELATIONS options in the PROC PRINQUAL statement, you can name this data set and control, to some extent, the contents of it.

Structure and Content

The output data set can have 16 different forms, depending on the specified combinations of the REPLACE, SCORES, APPROXIMATIONS, and CORRELATIONS options. You can specify any combination of these options. To illustrate, assume that the data matrix consists of N observations and m variables, and n components are computed. Then, define the following:

- D: the N x m matrix of original data with variable names that correspond to the names of the variables in the input data set. However, when you use the OPSCORE transformation on character variables, those variables are replaced by numeric variables that contain category numbers.
- T: the N x m matrix of transformed data with variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set.
The PRINQUAL Procedure

S the \( N \times n \) matrix of component scores with variable names constructed from the value of the PREFIX= option and integers

A the \( N \times m \) matrix of data approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set

\( R_{TD} \) the \( m \times m \) matrix of correlations between the transformed variables and the original variables with variable names that correspond to the names of the variables in the input data set. When missing values exist, casewise deletion is used to compute the correlations.

\( R_{TT} \) the \( m \times m \) matrix of correlations among the transformed variables with the variable names constructed from the value of the TPREFIX= option (if you do not specify the REPLACE option) and the names of the variables in the input data set

\( R_{TS} \) the \( m \times n \) matrix of correlations between the transformed variables and the principal component scores (component structure matrix) with variable names constructed from the value of the PREFIX= option and integers

\( R_{TA} \) the \( m \times m \) matrix of correlations between the transformed variables and the variable approximations with variable names constructed from the value of the APREFIX= option and the names of the variables in the input data set

To create a data set WORK.A that contains all information, specify the following options in the PROC PRINQUAL statement

```
proc prinqual scores approximations correlations out=a;
```

and also use a TRANSFORM statement appropriate for your data. Then the WORK.A data set contains

```
D T S A
R_{TD} R_{TT} R_{TS} R_{TA}
```

To eliminate the bottom partitions that contain the correlations and component structure, do not specify the CORRELATIONS option. For example, use the following PROC PRINQUAL statement with an appropriate TRANSFORM statement.

```
proc prinqual scores approximations out=a;
```

Then the WORK.A data set contains

```
D T S A
```

If you use the following PROC PRINQUAL statement (with an appropriate TRANSFORM statement)
proc prinqual out=a;

this creates a data set WORK.A of the form

\textbf{D T}

To output transformed data and component scores only, specify the following options in the PROC PRINQUAL statement:

\texttt{proc prinqual replace scores out=a;}

Then the WORK.A data set contains

\textbf{T S}

\textit{\_TYPE\_} and \textit{\_NAME\_} Variables

In addition to the preceding information, the output data set contains two character variables, the variable \_TYPE\_ (length 8) and the variable \_NAME\_ (length 32).

The \_TYPE\_ variable has the value ‘SCORE’ if the observation contains variables, transformed variables, components, or data approximations; the \_TYPE\_ variable has the value ‘CORR’ if the observation contains correlations or component structure.

By default, the \_NAME\_ variable has values ’ROW1’, ’ROW2’, and so on, for the observations with \_TYPE\_ = ‘SCORE’. If you use an ID statement, the variable \_NAME\_ contains the formatted ID variable for SCORES observations. The values of the variable \_NAME\_ for observations with \_TYPE\_ = ‘CORR’ are the names of the transformed variables.

Certain procedures, such as PROC PRINCOMP, which can use the PROC PRINQUAL output data set, issue a warning that the PROC PRINQUAL data set contains \_NAME\_ and \_TYPE\_ variables but is not a TYPE=CORR data set. You can ignore this warning.

Variable Names

The TPREFIX=, APREFIX=, and PREFIX= options specify prefixes for the transformed and approximation variable names and for principal component score variables, respectively. PROC PRINQUAL constructs transformed and approximation variable names from a prefix and the first characters of the original variable name. The number of characters in the prefix plus the number of characters in the original variable name (including the final digits, if any) required to uniquely designate the new variables should not exceed 32. For example, if the APREFIX= parameter that you specify is one character, PROC PRINQUAL adds the first 31 characters of the original variable name; if your prefix is four characters, only the first 28 characters of the original variable name are added.
Effect of the TSTANDARD= and COVARIANCE Options

The values in the output data set are affected by the TSTANDARD= and COVARIANCE options. If you specify TSTANDARD=NOMISS, the NOMISS standardization is performed on the transformed data after the iterations have been completed, but before the output data set is created. The new means and variances are used in creating the output data set. Then, if you do not specify the COVARIANCE option, the data are transformed to mean zero and variance one. The principal component scores and data approximations are computed from the resulting matrix. The data are then linearly transformed to have the mean and variance specified by the TSTANDARD= option. The data approximations are transformed so that the means within each pair of a transformed variable and its approximation are the same. The ratio of the variance of a variable approximation to the variance of the corresponding transformed variable equals the proportion of the variance of the variable that is accounted for by the components model.

If you specify the COVARIANCE option and do not specify TSTANDARD=Z, you can input the transformed data to PROC PRINCOMP, again specifying the COVARIANCE option, to perform a components analysis of the results of PROC PRINQUAL. Similarly, if you do not specify the COVARIANCE option with PROC PRINQUAL and you input the transformed data to PROC PRINCOMP without the COVARIANCE option, you receive the same report. However, some combinations of PROC PRINQUAL options, such as COVARIANCE and TSTANDARD=Z, while valid, produce approximations and scores that cannot be reproduced by PROC PRINCOMP.

The component scores in the output data set are computed from the correlations among the transformed variables, or from the covariances if you specified the COVARIANCE option. The component scores are computed after the TSTANDARD=NOMISS transformation, if specified. The means of the component scores in the output data set are always zero. The variances equal the corresponding eigenvalues, unless you specify the STANDARD option; then the variances are set to one.

Avoiding Constant Transformations

There are times when the optimal scaling produces a constant transformed variable. This can happen with the MONOTONE, UNTIE, and MSPLINE transformations when the target is negatively correlated with the original input variable. It can happen with all transformations when the target is uncorrelated with the original input variable. When this happens, the procedure modifies the target to avoid a constant transformation. This strategy avoids certain nonoptimal solutions.

If the transformation is monotonic and a constant transformed variable results, the procedure multiplies the target by $-1$ and tries the optimal scaling again. If the transformation is not monotonic or if the multiplication by $-1$ did not help, the procedure tries using a random target. If the transformation is still constant, the previous nonconstant transformation is retained. When a constant transformation is avoided by any strategy, this message is displayed: “A constant transformation was avoided for name.”
Constant Variables

Constant and almost constant variables are zeroed and ignored.

Character OPSCORE Variables

Character OPSCORE variables are replaced by a numeric variable containing category numbers before the iterations, and the character values are discarded. Only the first eight characters are considered when determining category membership. If you want the original character variable in the output data set, give it a different name in the OPSCORE specification (OPSCORE(x / name=(x2)) and name the original variable on the ID statement (ID x;).

REITERATE Option Usage

You can use the REITERATE option to perform additional iterations when PROC PRINQUAL stops before the data have adequately converged. For example, suppose that you execute the following code:

```latex
proc prinqual data=A cor out=B;
  transform mspline(X1-X5);
run;
```

If the transformations do not converge in the default 30 iterations, you can perform more iterations without repeating the first 30 iterations.

```latex
proc prinqual data=B reiterate cor out=B;
  transform mspline(X1-X5);
run;
```

Note that a WHERE statement is not necessary to exclude the correlation observations. They are automatically excluded because their _TYPE_ variable value is not ‘SCORE’.

You can also use the REITERATE option to specify starting values other than the original values for the transformations. Providing alternate starting points may avoid local optima. Here are two examples.

```latex
proc prinqual data=A out=B;
  transform rank(X1-X5);
run;

proc prinqual data=B reiterate out=C;
  /* Use ranks as the starting point. */
  transform monotone(X1-X5);
run;

data B;
  set A;
```
array TXS[5] TX1-TX5;
do j = 1 to 5;
   TXS[j] = normal(0);
end;
run;

proc prinqual data=B reiterate out=C;
   /* Use a random starting point. */
   transform monotone(X1-X5);
run;

Note that divergence with the REITERATE option, particularly in the second iteration, is not an error since the initial transformation is not required to be a valid member of the transformation family. When you specify the REITERATE option, the iteration does not terminate when the criterion change is negative during the first ten iterations.

### Passive Observations

Observations may be excluded from the analysis for several reasons, including zero weight, zero frequency, missing values in variables designated IDENTITY, or missing values with the NOMISS option specified. These observations are passive in that they do not contribute to determining transformations, $R^2$, total variance, and so on. However, some information can be computed for them, such as approximations, principal component scores, and transformed values. Passive observations in the output data set have a blank value for the variable _TYPE_.

Missing value estimates for passive observations may converge slowly with METHOD=MTV. In the following example, the missing value estimates should be 2, 5, and 8. Since the nonpassive observations do not change, the procedure converges in one iteration but the missing value estimates do not converge. The extra iterations produced by specifying CONVERGE=−1 and CCONVERGE=−1, as shown in the second PROC PRINQUAL step, generate the expected results.

```plaintext
data A;
   input X Y;
datalines;
1 1
2 .
3 3
4 4
5 .
6 6
7 7
8 .
9 9
;

proc prinqual nomiss data=A nomiss n=1 out=B method=mtv;
   transform lin(X Y);
run;
```
proc print;
run;

proc prinqual nomiss data=A nomiss n=1 out=B method=mtv
  converge=-1 cconverge=-1;
  transform lin(X Y);
run;
proc print;
run;

Computational Resources

This section provides information on the computational resources required to run PROC PRINQUAL.

Let

\[ N = \text{number of observations} \]
\[ m = \text{number of variables} \]
\[ n = \text{number of principal components} \]
\[ k = \text{maximum spline degree} \]
\[ p = \text{maximum number of knots} \]

- For the MTV algorithm, more than
  \[ 56m + 8Nm + 8 \left( 6N + (p + k + 2)(p + k + 11) \right) \]
  bytes of array space are required.
- For the MGV and MAC algorithms, more than \( 56m \) plus the maximum of the data matrix size and the optimal scaling work space bytes of array space are required. The data matrix size is \( 8Nm \) bytes. The optimal scaling work space requires less than \( 8 \left( 6N + (p + k + 2)(p + k + 11) \right) \) bytes.
- For the MTV and MGV algorithms, more than \( 56m + 4m(m + 1) \) bytes of array space are required.
- PROC PRINQUAL tries to store the original and transformed data in memory. If there is not enough memory, a utility data set is used, potentially resulting in a large increase in execution time. The amount of memory for the preceding data formulas are underestimates of the amount of memory needed to handle most problems. These formulas give an absolute minimum amount of memory required. If a utility data set is used, and if memory could be used with perfect efficiency, then roughly the amount of memory stated previously would be needed. In reality, most problems require at least two or three times the minimum.
• PROC PRINQUAL sorts the data once. The sort time is roughly proportional to \( mN^{3/2} \).

• For the MTV algorithm, the time required to compute the variable approximations is roughly proportional to \( 2Nm^2 + 5m^3 + nm^2 \).

• For the MGV algorithm, one regression analysis per iteration is required to compute model parameter estimates. The time required for accumulating the crossproduct matrix is roughly proportional to \( Nm^2 \). The time required to compute the regression coefficients is roughly proportional to \( m^3 \). For each variable for each iteration, the swept crossproduct matrix is updated with time roughly proportional to \( m(N+m) \). The swept crossproduct matrix is updated for each variable with time roughly proportional to \( m^2 \), until computations are refreshed, requiring all sweeps to be performed again.

• The only computationally intensive part of the MAC algorithm is the optimal scaling, since variable approximations are simple averages.

• Each optimal scaling is a multiple regression problem, although some transformations are handled with faster special case algorithms. The number of regressors for the optimal scaling problems depends on the original values of the variable and the type of transformation. For each monotone spline transformation, an unknown number of multiple regressions is required to find a set of coefficients that satisfies the constraints. The B-spline basis is generated twice for each SPLINE and MSPLINE transformation for each iteration. The time required to generate the B-spline basis is roughly proportional to \( Nk^2 \).

**Displayed Output**

The main output from the PRINQUAL procedure is the output data set. However, the procedure does produce displayed output in the form of an iteration history table that includes the following:

• Iteration Number
• the criterion being optimized
• criterion change
• Maximum and Average Absolute Change in standardized variable scores computed over variables that can be iteratively transformed
• notes
• final convergence status

**ODS Table Names**

PROC PRINQUAL assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

For more information on ODS, see Chapter 14, “Using the Output Delivery System.”
Table 59.2. ODS Tables Produced in PROC PRINQUAL

**ODS Graphics (Experimental)**

This section describes the use of ODS for creating graphics with the PRINQUAL procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release. To request a graph you must specify the ODS GRAPHICS statement in addition to the following option. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

The following table shows the available plot option.

<table>
<thead>

**ODS Graph Names**

PROC PRINQUAL assigns a name to the graph it creates using ODS. You can use this name to reference the graph when using ODS. The name is listed in Table 59.3.

To request a graph you must specify the ODS GRAPHICS statement in addition to the option indicated in Table 59.3. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

**Examples**

**Example 59.1. Multidimensional Preference Analysis of Cars Data**

This example uses PROC PRINQUAL to perform a nonmetric multidimensional preference (MDPREF) analysis (Carroll 1972). MDPREF analysis is a principal component analysis of a data matrix with columns that correspond to people and rows that correspond to objects. The data are ratings or rankings of each person’s preference for each object. The data are the transpose of the usual multivariate data matrix. (In
other words, the columns are people instead of the more typical matrix where rows represent people.) The final result of an MDPREF analysis is a biplot (Gabriel 1981) of the resulting preference space. A biplot displays the judges and objects in a single plot by projecting them onto the plane in the transformed variable space that accounts for the most variance.

The data are ratings by 25 judges of their preference for each of 17 automobiles. The ratings are made on a 0 to 9 scale, with 0 meaning very weak preference and 9 meaning very strong preference for the automobile. These judgments were made in 1980 about that year’s products. There are two additional variables that indicate the manufacturer and model of the automobile.

This example uses PROC PRINQUAL, PROC FACTOR, and the %PLOTIT macro. PROC FACTOR is used before PROC PRINQUAL to perform a principal component analysis of the raw judgments. PROC FACTOR is also used immediately after PROC PRINQUAL since PROC PRINQUAL is a scoring procedure that optimally scores the data but does not report the principal component analysis.

The %PLOTIT macro produces the biplot. For information on the %PLOTIT macro, see Appendix B, “Using the %PLOTIT Macro.”

The scree plot, in the standard principal component analysis reported by PROC FACTOR, shows that two principal components should be retained for further use. (See the scree plot in Output 59.1.1 —there is a clear separation between the first two components and the remaining components.) There are nine eigenvalues that are precisely zero because there are nine fewer observations than variables in the data matrix. PROC PRINQUAL is then used to monotonically transform the raw judgments to maximize the proportion of variance accounted for by the first two principal components. The following statements create the data set and perform a principal component analysis of the original data. These statements produce Output 59.1.1.

Preference Ratings for Automobiles Manufactured in 1980

Principal Components of Original Data

The FACTOR Procedure

Initial Factor Method: Principal Components

Scree Plot of Eigenvalues

Number
To fit the nonmetric MDPREF model, you can use the PRINQUAL procedure. The MONOTONE option is specified in the TRANSFORM statement to request a nonmetric MDPREF analysis; alternatively, you can instead specify the IDENTITY option for a metric analysis. Several options are used in the PROC PRINQUAL statement. The option DATA=CarPref specifies the input data set, OUT=Results creates an output data set, and N=2 and the default METHOD=MTV transform the data to better fit a two-component model. The REPLACE option replaces the original data with the monotonically transformed data in the OUT= data set. The MDPREF option standardizes the component scores to variance one so that the geometry of the biplot is correct, and it creates two variables in the OUT= data set named Prin1 and Prin2. These variables contain the standardized in the OUT= data set named Prin1 and Prin2. These variables contain the standardized in the OUT= data set named Prin1 and Prin2. These variables contain the standardized in the OUT= data set named Prin1 and Prin2. These variables contain the standardized

$X = V \Lambda^{1/2} W'$ is the principal component model, where $X'X/(n-1) = W\Lambda W'$. The $W$ and $\Lambda$ contain the eigenvectors and eigenvalues of the correlation matrix of $X$. The first two columns of $V$, the standardized component scores, and $W\Lambda^{1/2}$, which is the structure matrix, are output. The advantage of creating a biplot based on principal components is that coordinates do not depend on the sample size. The following statements transform the data and produce Output 59.1.2.

```plaintext
* Transform the Data to Better Fit a Two Component Model;
proc prinqual data=CarPref out=Results n=2 replace mdpref;
  id model;
  transform monotone(Judge1-Judge25);
  title2 'Multidimensional Preference (MDPREF) Analysis';
  title3 'Optimal Monotonic Transformation of Preference Data';
run;
```

</table>

WARNING: Failed to converge, however criterion change is less than 0.0001.

The iteration history displayed by PROC PRINQUAL indicates that the proportion of variance is increased from an initial 0.66946 to 0.82995. The proportion of variance accounted for by PROC PRINQUAL on the first iteration equals the cumulative proportion of variance shown by PROC FACTOR for the first two principal components. In this example, PROC PRINQUAL’s initial iteration performs a standard principal component analysis of the raw data. The columns labeled Average Change, Maximum Change, and Variance Change contain values that always decrease, indicating that PROC PRINQUAL is improving the transformations at a monotonically decreasing rate over the iterations. This does not always happen, and when it does not, it suggests that the analysis may be converging to a degenerate solution. See Example 59.3 on page 3688 for a discussion of a degenerate solution. The algorithm does not converge in 30 iterations. However, the criterion change is small, indicating that more iterations are unlikely to have much effect on the results.
The second PROC FACTOR analysis is performed on the transformed data. The WHERE statement is used to retain only the monotonically transformed judgments. The scree plot shows that the first two eigenvalues are now much larger than the remaining smaller eigenvalues. The second eigenvalue has increased markedly at the expense of the next several eigenvalues. Two principal components seem to be necessary and sufficient to adequately describe these judges’ preferences for these automobiles. The cumulative proportion of variance displayed by PROC FACTOR for the first two principal components is 0.83. The following statements perform the analysis and produce Output 59.1.3:

```
* Final Principal Component Analysis;
proc factor data=Results nfactors=2 scree;
   ods select Eigenvalues ScreePlot;
   var Judge1-Judge25;
   where _TYPE_='SCORE';
   title3 'Principal Components of Monotonically Transformed Data';
run;
```

Preference Ratings for Automobiles Manufactured in 1980
Multidimensional Preference (MDPREF) Analysis
Principal Components of Monotonically Transformed Data

The FACTOR Procedure
Initial Factor Method: Principal Components

Scree Plot of Eigenvalues
The remainder of the example constructs the MDPREF biplot. A biplot is a plot that displays the relation between the row points and the columns of a data matrix. The rows of $V$, the standardized component scores, and $W^{1/2}_{\Lambda}$, which is the structure matrix, contain enough information to reproduce $X$. The $(i,j)$ element of $X$ is the product of row $i$ of $V$ and row $j$ of $W^{1/2}_{\Lambda}$. If all but the first two columns of $V$ and $W^{1/2}_{\Lambda}$ are discarded, the $(i,j)$ element of $X$ is approximated by the product of row $i$ of $V$ and row $j$ of $W^{1/2}_{\Lambda}$.

Since the MDPREF analysis is based on a principal component model, the dimensions of the MDPREF biplot are the first two principal components. The first principal component is the longest dimension through the MDPREF biplot. The first principal component is overall preference, which is the most salient dimension in the preference judgments. One end points in the direction that is on the average preferred most by the judges, and the other end points in the least preferred direction. The second principal component is orthogonal to the first principal component, and it is the orthogonal direction that is the second most salient. The interpretation of the second dimension varies from example to example.

With an MDPREF biplot, it is geometrically appropriate to represent each automobile (object) by a point and each judge by a vector. The automobile points have coordinates that are the scores of the automobile on the first two principal components. The judge vectors emanate from the origin of the space and go through a point with coordinates that are the coefficients of the judge (variable) on the first two principal components.

The absolute length of a vector is arbitrary. However, the relative lengths of the vectors indicate fit, with the squared lengths being proportional to the communalities in the PROC FACTOR output. The direction of the vector indicates the direction that is most preferred by the individual judge, with preference increasing as the vector moves from the origin. Let $v'$ be row $i$ of $V$, $u'$ be row $j$ of $U = W^{1/2}_{\Lambda}$, $\|v\|$ be the length of $v$, $\|u\|$ be the length of $u$, and $\theta$ be the angle between $v$ and $u$. The predicted degree of preference that an individual judge has for an automobile is $u'v = \|u\| \|v\| \cos \theta$. Each car point can be orthogonally projected onto the vector. The projection of car $i$ on vector $j$ is $u((u'v)/(u'u))$ and the length of this projection is $\|v\| \cos \theta$. The automobile that projects farthest along a vector in the direction it points is that judge’s most preferred automobile, since the length of this projection, $\|v\| \cos \theta$, differs from the predicted preference, $\|u\| \|v\| \cos \theta$, only by $\|u\|$, which is constant within each judge.

To interpret the biplot, look for directions through the plot that show a continuous change in some attribute of the automobiles, or look for regions in the plot that contain clusters of automobile points and determine what attributes the automobiles have in common. Those points that are tightly clustered in a region of the plot represent automobiles that have the same preference patterns across the judges. Those vectors that point in roughly the same direction represent judges who tend to have similar preference patterns.
The following statement constructs the biplot and produces Output 59.1.4:

```sas
title3 'Biplot of Automobiles and Judges';
%plotit(data=results, datatype=mdpref 2);
```

The DATATYPE=MDPREF 2 option indicates that the coordinates come from an MDPREF analysis, so the macro represents the scores as points and the structure as vectors, with the vectors stretched by a factor of two to make a better graphical display.

**Output 59.1.4.** Preference Ratings for Automobiles Manufactured in 1980

In the biplot, American automobiles are located on the left of the space, while European and Japanese automobiles are located on the right. At the top of the space are expensive American automobiles (Cadillac Eldorado, Lincoln Continental) while at the bottom are inexpensive ones (Pinto, Chevette). The first principal component differentiates American from imported automobiles, and the second arranges automobiles by price and other associated characteristics.

The two expensive American automobiles form a cluster, the sporty automobile (Firebird) is by itself, the Volvo DL is by itself, and the remaining imported autos
form a cluster, as do the remaining American autos. It seems there are 5 prototypical automobiles in this set of 17, in terms of preference patterns among the 25 judges.

Most of the judges prefer the imported automobiles, especially the Volvo. There is also a fairly large minority that prefer the expensive cars, whether or not they are American (those with vectors that point towards one o’clock), or simply prefer expensive American automobiles (vectors that point towards eleven o’clock). There are two people who prefer anything except expensive American cars (five o’clock vectors), and one who prefers inexpensive American cars (seven o’clock vector).

Several vectors point toward the upper-right corner of the plot, toward a region with no cars. This is the region between the European and Japanese cars on the right and the luxury cars on the top. This suggests that there is a market for luxury Japanese and European cars.

Example 59.2. Multidimensional Preference Analysis of Cars Data, ODS Graphics (Experimental)

The following graphical displays are requested by specifying the experimental ODS GRAPHICS statement. For general information about ODS graphics see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the PRINQUAL procedure, see the “ODS Graphics” section on page 3677.

Output 59.2.1. Multidimensional Preference Analysis (Experimental)

Example 59.3. Principal Components of Basketball Rankings

The data in this example are 1985–1986 preseason rankings of 35 college basketball teams by 10 different news services. The services do not all rank the same teams or the same number of teams, so there are missing values in these data. Each of the 35 teams in the data set is ranked by at least one news service. One way of summarizing these data is with a principal component analysis, since the rankings should all be related to a single underlying variable, the first principal component.

You can use PROC PRINQUAL to estimate the missing ranks and compute scores for all observations. You can formulate a PROC PRINQUAL analysis that assumes that the observed ranks are ordinal variables and replaces the ranks with new numbers that are monotonic with the ranks and better fit the one principal component model.
The missing rank estimates need to be constrained since a news service would have positioned the unranked teams below the teams it ranked. PROC PRINQUAL should impose order constraints within the nonmissing values and between the missing and nonmissing values, but not within the missing values. PROC PRINQUAL has sophisticated missing data handling facilities; however, these facilities cannot directly handle this problem. The solution requires reformulating the problem.

By performing some preliminary data manipulations, specifying the N=1 option in the PROC PRINQUAL statement, and specifying the UNTIE transformation in the TRANSFORM statement, you can make the missing value estimates conform to the requirements. The PROC MEANS step finds the largest rank for each variable. The next DATA step replaces missing values with a value that is one larger than the largest observed rank. The N=1 option (in the PRINQUAL procedure) specifies that the variables should be transformed to make them as one-dimensional as possible. The UNTIE transformation in the TRANSFORM statement monotonically transforms the ranks, untying any ties in an optimal way. Because the only ties are for the values that replace the missing values, and because these values are larger than the observed values, the rescoring of the data satisfies the preceding requirements.

The following statements create the data set and perform the transformations discussed previously. These statements produce Output 59.3.1.

* Example 2: Basketball Data
* Preseason 1985 College Basketball Rankings
* (rankings of 35 teams by 10 news services)
* Note: (a) Various news services rank varying numbers of teams.
* (b) Not all 35 teams are ranked by all news services.
* (c) Each team is ranked by at least one service.
* (d) Rank 20 is missing for UPI.;

An alternative approach is to use the pairwise deletion option of the CORR procedure to compute the correlation matrix and then use PROC PRINCOMP or PROC FACTOR to perform the principal component analysis. This approach has several disadvantages. The correlation matrix may not be positive semidefinite (psd), an assumption required for principal component analysis. PROC PRINQUAL always produces a psd correlation matrix. Even with pairwise deletion, PROC CORR removes the six observations with only a single nonmissing value from this data set. Finally, it is still not possible to calculate scores on the principal components for those teams that have missing values.

It is possible to compute the composite ranking using PROC PRINCOMP and some preliminary data manipulations, similar to those discussed previously. 

Chapter 58, “The PRINCOMP Procedure,” contains an example where the average
of the unused ranks in each poll is substituted for the missing values, and each observation is weighted by the number of nonmissing values. This method has much to recommend it. It is much faster and simpler than using PROC PRINQUAL. It is also much less prone to degeneracies and capitalization on chance. However, PROC PRINCOMP does not allow the nonmissing ranks to be monotonically transformed and the missing values untied to optimize fit.

PROC PRINQUAL monotonically transforms the observed ranks and estimates the missing ranks (within the constraints given previously) to account for almost 95 percent of the variance of the transformed data by just one dimension. PROC FACTOR is then used to report details of the principal component analysis of the transformed data. As shown by the Factor Pattern values in Output 59.3.2, nine of the ten news services have a correlation of 0.95 or larger with the scores on the first principal component after the data are optimally transformed. The scores are sorted and the composite ranking is displayed following the PROC FACTOR output. More confidence can be placed in the stability of the scores for the teams that are ranked by the majority of the news services than in scores for teams that are seldom ranked.

The monotonic transformations are plotted for each of the ten news services. These plots are the values of the raw ranks (with the missing ranks replaced by the maximum rank plus one) versus the rescored (transformed) ranks. The transformations are the step functions that maximize the fit of the data to the principal component model. Smoother transformations could be found by using MSPLINE transformations, but MSPLINE transformations would not correctly handle the missing data problem.

The following statements perform the final analysis and produce Output 59.3.2:

Output 59.3.3. Monotonic Transformation for Each News Service
Output 59.3.3. (continued)
Output 59.3.3. (continued)

The ordinary PROC PRINQUAL missing data handling facilities do not work for these data because they do not constrain the missing data estimates properly. If you code the missing ranks as missing and specify linear transformations, then you can compute least-squares estimates of the missing values without transforming the observed values. The first principal component then accounts for 92 percent of the variance after 20 iterations. However, Virginia Tech is ranked number 11 by its score even though it appeared in only one poll (InsideSports ranked it number 13, anchoring it firmly in the middle). Specifying monotone transformations is also inappropriate since they too allow unrated teams to move in between ranked teams.

With these data, the combination of monotone transformations and the freedom to score the missing ranks without constraint leads to degenerate transformations. PROC PRINQUAL tries to merge the 35 points into two points, producing a perfect fit in one dimension. There is evidence for this after 20 iterations when the Average Change, Maximum Change, and Variance Change values are all increasing, instead of the more stable decreasing change rate seen in the analysis shown. The change rates all stop increasing after 41 iterations, and it is clear by 70 or 80 iterations that one component will account for 100 percent of the transformed variables variance after sufficient iteration. While this may seem desirable (after all, it is a perfect fit), you should, in fact, be on guard when this happens. Whenever convergence is slow, the rates of change increase, or the final data perfectly fit the model, the solution is probably degenerating due to too few constraints on the scorings.
PROC PRINQUAL can account for 100 percent of the variance by scoring Montana and UCLA with one positive value on all variables and scoring all the other teams with one negative value on all variables. This inappropriate analysis suggests that all ranked teams are equally good except for two teams that are less good. Both of these two teams are ranked by only one news service, and their only nonmissing rank is last in the poll. This accounts for the degeneracy.

The PROBIT procedure calculates maximum likelihood estimates of regression parameters and the natural (or threshold) response rate for quantal response data from biological assays or other discrete event data. This includes probit, logit, ordinal logistic, and extreme value (or gompit) regression models.

Probit analysis developed from the need to analyze qualitative (dichotomous or polytomous) dependent variables within the regression framework. Many response variables are binary by nature (yes/no), while others are measured ordinally rather than continuously (degree of severity). Collett (1991) and Agresti (1990), for example, have shown ordinary least squares (OLS) regression to be inadequate when the dependent variable is discrete. Probit or logit analyses are more appropriate in this case.

The PROBIT procedure computes maximum likelihood estimates of the parameters $\beta$ and $C$ of the probit equation using a modified Newton-Raphson algorithm. When the response $Y$ is binary, with values 0 and 1, the probit equation is

$$ p = \Pr(Y = 0) = C + (1 - C)F(x'\beta) $$

where

- $\beta$ is a vector of parameter estimates
- $F$ is a cumulative distribution function (the normal, logistic, or extreme value)
- $x$ is a vector of explanatory variables
- $p$ is the probability of a response
- $C$ is the natural (threshold) response rate

Notice that PROC PROBIT, by default, models the probability of the lower response levels. The choice of the distribution function $F$ (normal for the probit model, logistic for the logit model, and extreme value or Gompertz for the gompit model) determines the type of analysis. For most problems, there is relatively little difference between the normal and logistic specifications of the model. Both distributions are symmetric about the value zero. The extreme value (or Gompertz) distribution, however, is not symmetric, approaching 0 on the left more slowly than it approaches 1 on the right. You can use the extreme value distribution where such asymmetry is appropriate.

For ordinal response models, the response, $Y$, of an individual or an experimental unit may be restricted to one of a (usually small) number, $k + 1 (k \geq 1)$, of ordinal values, denoted for convenience by $1, \ldots, k, k + 1$. For example, the severity of coronary disease can be classified into three response categories as 1=none disease, 2=angina
pectoris, and 3=myocardial infarction. The PROBIT procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

\[
\Pr(Y \leq 1 \mid x) = F(x'\beta)
\]

\[
\Pr(Y \leq i \mid x) = F(\alpha_i + x'\beta), \quad 2 \leq i \leq k
\]

where \(\alpha_2, \ldots, \alpha_k\) are \(k - 1\) intercept parameters. By default, the covariate vector \(x\) contains an overall intercept term.

You can set or estimate the natural (threshold) response rate \(C\). Estimation of \(C\) can begin either from an initial value that you specify or from the rate observed in a control group. By default, the natural response rate is fixed at zero.

An observation in the data set analyzed by the PROBIT procedure may contain the response and explanatory values for one subject. Alternatively, it may provide the number of observed events from a number of subjects at a particular setting of the explanatory variables. In this case, PROC PROBIT models the probability of an event.

### Getting Started

The following example illustrates how you can use the PROBIT procedure to compute the threshold response rate and regression parameter estimates for quantal response data.

#### Estimating the Natural Response Threshold Parameter

Suppose you want to test the effect of a drug at 12 dosage levels. You randomly divide 180 subjects into 12 groups of 15—one group for each dosage level. You then conduct the experiment and, for each subject, record the presence or absence of a positive response to the drug. You summarize the data by counting the number of subjects responding positively in each dose group. Your data set is as follows:

```plaintext
data study;
  input Dose Respond;
  Number = 15;
datalines;
0 3
1.1 4
1.3 4
2.0 3
2.2 5
2.8 4
3.7 5
3.9 9
4.4 8
```

The variable **dose** represents the amount of drug administered. The first group, receiving a dose level of 0, is the control group. The variable **number** represents the number of subjects in each group. All groups are equal in size; hence, **number** has the value 15 for all observations. The variable **respond** represents the number of subjects responding to the associated drug dosage.

You can model the probability of positive response as a function of dosage using the following statements:

```sas
proc probit data=study log10 optc;  
  model respond/number=dose;  
  output out=new p=p_hat;  
  predpplot var=dose cfit=blue cframe=ligr inborder;  
  inset;  
  ipppplot var=dose cfit=blue cframe=ligr inborder;  
  inset;  
run;
```

The **DATA=** option specifies that PROC PROBIT analyze the SAS data set **study**. The **LOG10** option replaces the first continuous independent variable (**dose**) by its common logarithm. The **OPTC** option estimates the natural response rate. When you use the **LOG10** option with the **OPTC** option, any observations with a dose value less than or equal to zero are used in the estimation as a control group.

The **OUTPUT** statement creates a new data set, **new**, that contains all the variables in the original data set, and a new variable, **p_hat**, that represents the predicted probabilities.

The **MODEL** statement specifies a proportional response using the variables **respond** and **number** in **events/trials** syntax. The variable **dose** is the stimulus or explanatory variable. The results from this analysis are displayed in the following figures.
Figure 60.1. Model Fitting Information for the PROBIT Procedure

Figure 60.1 displays background information about the model fit. Included are the name of the input data set, the response variables used, and the number of observations, events, and trials. The last line in Figure 60.1 shows the final value of the log-likelihood function.

Figure 60.2 displays the table of parameter estimates for the model. The parameter $C$, which is the natural response threshold or the proportion of individuals responding at zero dose, is estimated to be 0.2409. Since both the intercept and the slope coefficient have significant $p$-values (0.0020, 0.0010), you can write the model for

$$\text{Pr(response)} = C + (1 - C')F(x'\beta)$$

as

$$\text{Pr(response)} = 0.2409 + 0.7591(\Phi(-4.1439 + 6.2308 \times \log_{10}(\text{dose})))$$

where $\Phi$ is the normal cumulative distribution function.

Figure 60.2. Model Parameter Estimates for the PROBIT Procedure

Finally, PROC PROBIT specifies the resulting tolerance distribution by providing the mean MU and scale parameter SIGMA as well as the covariance matrix of the distribution parameters.

**Figure 60.3.** Tolerance Distribution Estimates for the PROBIT Procedure

**Figure 60.4.** Plot of Observed and Fitted Probabilities versus Dose Level

The PREDPPLOT statement creates the plot in Figure 60.4, showing the relationship between dosage level, observed response proportions, and estimated probability values. The dashed lines represent pointwise confidence bands for the fitted probabilities, and a reference line is plotted at the estimated threshold value of .24.
Figure 60.5. Inverse Predicted Probability Plot with Fiducial Limits

The IPPPLOT statement creates the plot in Figure 60.5, showing the inverse relationship between dosage level and observed response proportions/estimated probability values. The dashed lines represent pointwise fiducial limits for the predicted values of the dose variable, and a reference line is also plotted at the estimated threshold value of .24.

The INSET statement after each of these plot statements draws a box within the plot. In the inset box, summary information about the model fitting is printed.

Syntax

The following statements are available in PROC PROBIT.

```
PROC PROBIT < options > ;
   MODEL response=independents < / options > ;
   BY variables ;
   CLASS variables ;
   OUTPUT < OUT=SAS-data-set > < options > ;
   WEIGHT variable ;
   CDFPLOT < VAR = variable > < options > ;
   INSET < keyword-list > < / options > ;
   IPPPLOT < VAR = variable > < options > ;
   LPREDPLOT < VAR = variable > < options > ;
   PREDPPLOT < VAR = variable > < options > ;
```
A MODEL statement is required. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last one is used. Main effects and higher-order terms can be specified in the MODEL statement, similar to the GLM procedure. If a CLASS statement is used, it must precede the MODEL statement.

The CDFPLOT, INSET, IPPPLOT, LPREDPLOT, and PREDPLOT statements are used to produce graphical output. You can use any appropriate combination of the graphical statements after the MODEL statement.

PROC PROBIT Statement

PROC PROBIT < options > ;

The PROC PROBIT statement starts the procedure. You can specify the following options in the PROC PROBIT statement.

COVOUT
writes the parameter estimate covariance matrix to the OUTEST= data set.

C=rate

OPTC
controls how the natural response is handled. Specify the OPTC option to request that the natural response rate $C$ be estimated. Specify the C=rate option to set the natural response rate or to provide the initial estimate of the natural response rate. The natural response rate value must be a number between 0 and 1.

- If you specify neither the OPTC nor the C= option, a natural response rate of zero is assumed.
- If you specify both the OPTC and the C= option, the C= option should be a reasonable initial estimate of the natural response rate. For example, you could use the ratio of the number of responses to the number of subjects in a control group.
- If you specify the C= option but not the OPTC option, the natural response rate is set to the specified value and not estimated.
- If you specify the OPTC option but not the C= option, PROC PROBIT's action depends on the response variable, as follows:
  - If you specify either the LN or LOG10 option and some subjects have the first independent variable (dose) values less than or equal to zero, these subjects are treated as a control group. The initial estimate of $C$ is then the ratio of the number of responses to the number of subjects in this group.
  - If you do not specify the LN or LOG10 option or if there is no control group, then one of the following occurs:
    - If all responses are greater than zero, the initial estimate of the natural response rate is the minimal response rate (the ratio of the number of responses to the number of subjects in a dose group) across all dose levels.
If one or more of the responses is zero (making the response rate zero in that dose group), the initial estimate of the natural rate is the reciprocal of twice the largest number of subjects in any dose group in the experiment.

**DATA=SAS-data-set**

specifies the SAS data set to be used by PROC PROBIT. By default, the procedure uses the most recently created SAS data set.

**GOUT=graphics-catalog**

specifies a graphics catalog in which to save graphics output.

**HPROB=p**

specifies a minimum probability level for the Pearson chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the t distribution with degrees of freedom equal to \((k - 1) \times m - q\), where \(k\) is the number of levels for the response variable, \(m\) is the number of different sets of independent variable values, and \(q\) is the number of parameters fit in the model. Note that the HPROB= option can also appear in the MODEL statement.

**INEST=SAS-data-set**

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section “INEST=SAS-data-set” on page 3757 for a detailed description of the contents of the INEST= data set.

**INVERSECL**

computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. If the algorithm fails to converge (this can happen when \(C\) is nonzero), missing values are reported for the confidence limits. See the section “Inverse Confidence Limits” on page 3761 for details. Note that the INVERSECL option can also appear in the MODEL statement.

**LACKFIT**

performs two goodness-of-fit tests (a Pearson chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option for this end. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the events/trials syntax.

**Note:** This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.
If the Pearson chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the “Lack of Fit Tests” section on page 3759 for a description of the tests. Note that the LACKFIT option can also appear in the MODEL statement.

**LOG**

**LN**

analyzes the data by replacing the first continuous independent variable by its natural logarithm. This variable is usually the level of some treatment such as dosage. In addition to the usual output given by the INVERSECL option, the estimated dose values and 95% fiducial limits for dose are also displayed. If you specify the OPTC option, any observations with a dose value less than or equal to zero are used in the estimation as a control group. If you do not specify the OPTC option with the LOG or LN option, then any observations with the first continuous independent variable values less than or equal to zero are ignored.

**LOG10**

specifies an analysis like that of the LN or LOG option except that the common logarithm (log to the base 10) of the dose value is used rather than the natural logarithm.

**NAMELEN=n**

specifies the length of effect names in tables and output data sets to be \( n \) characters, where \( n \) is a value between 20 and 200. The default length is 20 characters.

**NOPRINT**

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 14, “Using the Output Delivery System.”

**OPTC**

controls how the natural response is handled. See the description of the C= option on page 3711 for details.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sorting order for the levels of the classification variables specified in the CLASS statement, including the levels of the response variable. Response level ordering is important since PROC PROBIT always models the probability of response levels at the beginning of the ordering. See the section “Response Level Ordering” on page 3754 for further details. This ordering also determines which parameters in the model correspond to each level in the data. The following table shows how PROC PROBIT interprets values of the ORDER= option.

<table>
<thead>
<tr>
<th>Value of ORDER=</th>
<th>Levels Sorted By</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>order of appearance in the input data set</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>formatted value</td>
</tr>
<tr>
<td>FREQ</td>
<td>descending frequency count; levels with the most observations come first in the order</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>unformatted value</td>
</tr>
</tbody>
</table>
By default, ORDER=FORMATTED. For the values FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, see the chapter on the SORT procedure in the SAS Procedures Guide.

**OUTEST= SAS-data-set**
specifies a SAS data set to contain the parameter estimates and, if the COVOUT option is specified, their estimated covariances. If you omit this option, the output data set is not created. The contents of the data set are described in the section “OUTEST= SAS-data-set” on page 3762.

**XDATA= SAS-data-set**
specifies an input SAS data set that contains values for all the independent variables in the MODEL statement and variables in the CLASS statement. If there are covariates specified in a MODEL statement, you specify fixed values for the effects in the MODEL statement by the XDATA= data set when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. These specified values for the effects in the MODEL statement are also used for generating plots. See the section “XDATA= SAS-data-set” on page 3763 for a detailed description of the contents of the XDATA= data set.

**BY Statement**

```bocode```
BY  variables ;
```
You can specify a BY statement with PROC PROBIT to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order on each of the BY variables, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the PROBIT procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.
CDFPLOT Statement

CDFPLOT <var = variable> <options>;

The CDFPLOT statement plots the predicted cumulative distribution function (CDF) of the multinomial response variable as a function of a single continuous independent variable (dose variable). You can only use this statement after a multinomial model statement.

VAR= (variable)
specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted cumulative distribution function is defined as

\[
\hat{F}_j(x) = C + (1 - C) F(\hat{a}_j + x'\hat{b})
\]

where \( j = 1, \ldots, k \) are the indexes of the \( k \) levels of the multinomial response variable, \( F \) is the CDF of the distribution used to model the cumulative probabilities, \( \hat{b} \) is the vector of estimated parameters, \( x \) is the covariate vector, \( \hat{a}_j \) are estimated ordinal intercepts with \( \hat{a}_1 = 0 \), and \( C \) is the threshold parameter, either known or estimated from the model. Let \( x_1 \) be the covariate corresponding to the dose variable and \( x_{-1} \) be the vector of the rest of the covariates. Let the corresponding estimated parameters be \( \hat{b}_1 \) and \( \hat{b}_{-1} \). Then

\[
\hat{F}_j(x) = C + (1 - C) F(\hat{a}_j + x_1\hat{b}_1 + x_{-1}'\hat{b}_{-1})
\]

To plot \( \hat{F}_j \) as a function of \( x_1, x_{-1} \) must be specified. You can use the XDATA= option to provide the values of \( x_{-1} \) (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options
specify the levels of the multinomial response variable for which the cdf curves are requested, and add features to the plot. There are \( k - 1 \) curves for a \( k \)-level multinomial response variable (for the highest level, it is the constant line 1). You can specify any of them to be plotted by the LEVEL= option in the CDFPLOT statement. See the LEVEL= option for how to specify the levels.

An attached box on the right side of the plot is used to label these curves with the names of their levels. You can specify the color of this box using the CLABBOX= option.
You can use options in the CDFPLOT statement to

- superimpose specification limits
- specify the levels for which the cdf curves are requested
- specify graphical enhancements (such as color or text height)

**Summary of Options**

The following tables list all options by function. The “Dictionary of Options” on page 3718 describes each option in detail.

**CDF Options**

**Table 60.1.** Options for CDFPLOT

<table>

Dictionary of Options

The following entries provide detailed descriptions of the options in the CDFPLOT statement.

**ANNOTATE=SAS-data-set**

**ANNO=SAS-data-set**

specifies an ANNOTATE data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the cdf plot. The ANNOTATE= data set you specify in the CDFPLOT statement is used for all plots created by the statement.

**CAXIS=color**

**CAXES=color**

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

**CFIT=color**

specifies the color for the fitted cdf curves. The default is the first color in the device color list.

**CFRAME=color**

**CFR=color**

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

**CGRID=color**

specifies the color for grid lines. The default is the first color in the device color list.

**CLABBOX=color**

specifies the color for the area enclosed by the label box for cdf curves. This area is not shaded by default.
CHREF=color
CH=color
specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=color
specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=color
CV=color
specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='string'
DES='string'
specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=font
specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=value1 to value2<by value3>
specifies tick mark values for the horizontal axis. value1, value2, and value3 must be numeric, and value1 must be less than value2. The lower tick mark is value1. Tick marks are drawn at increments of value3. The last tick mark is the greatest value that does not exceed value2. If value3 is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

\[
\begin{align*}
\text{haxis} & = 0 \text{ to } 10 \\
\text{haxis} & = 2 \text{ to } 10 \text{ by } 2 \\
\text{haxis} & = 0 \text{ to } 200 \text{ by } 10
\end{align*}
\]

HEIGHT=value
specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

HLOWER=value
specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies value as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.
HOFFSET=value
    specifies offset for horizontal axis. The default value is 1.

HUPPER=value
    specifies value as the upper horizontal axis tick mark. The tick mark interval and
    the lower axis limit are determined automatically. This option has no effect if the
    HAXIS= option is used.

HREF<(INTERSECT)> =value-list
    requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is
    specified, a second reference line perpendicular to the vertical axis is drawn that
    intersects the fit line at the same point as the horizontal axis reference line. If a
    horizontal axis reference line label is specified, the intersecting vertical axis reference
    line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=,
    and LHREF= options.

HREFLABELS=’label1’, . . . ,’labeln’
HREFLABEL=’label1’, . . . ,’labeln’
HREFLAB=’label1’, . . . ,’labeln’
    specifies labels for the lines requested by the HREF= option. The number of labels
    must equal the number of lines. Enclose each label in quotes. Labels can be up to 16
    characters.

HREFLABPOS=n
    specifies the vertical position of labels for HREF= lines. The following table shows
    valid values for n and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>top</td>
</tr>
<tr>
<td>2</td>
<td>staggered from top</td>
</tr>
<tr>
<td>3</td>
<td>bottom</td>
</tr>
<tr>
<td>4</td>
<td>staggered from bottom</td>
</tr>
<tr>
<td>5</td>
<td>alternating from top</td>
</tr>
<tr>
<td>6</td>
<td>alternating from bottom</td>
</tr>
</tbody>
</table>

INBORDER
    requests a border around cdf plots.

LEVEL= (character-list)
ORDINAL= (character-list)
    specifies the names of the levels for which cdf curves are requested. Names should
    be quoted and separated by space. If there is no correct name provided, no cdf curve
    is plotted.

LFIT=linetype
    specifies a line style for fitted curves. By default, fitted curves are drawn by connect-
    ing solid lines (linetype = 1).
LGRID=linetype
specifies a line style for all grid lines. linetype is between 1 and 46. The default is 35.

LHREF=linetype
LH=linetype
specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

LVREF=linetype
LV=linetype
specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME=’string’
specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is ’PROBIT’.

NOFIT
suppresses the fitted cdf curves.

NOFRAME
suppresses the frame around plotting areas.

NOGRID
suppresses grid lines.

NOHLABEL
suppresses horizontal labels.

NOHTICK
suppresses horizontal tick marks.

NOTHRESH
suppresses the threshold line.

NOVLABEL
suppresses vertical labels.

NOVTICK
suppresses vertical tick marks.

THRESHLABPOS=n
specifies the horizontal position of labels for the threshold line. The following table shows valid values for n and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>left</td>
</tr>
<tr>
<td>2</td>
<td>right</td>
</tr>
</tbody>
</table>
VAXIS=\texttt{value1 to value2 by value3}

specifies tick mark values for the vertical axis. \texttt{value1}, \texttt{value2}, and \texttt{value3} must be numeric, and \texttt{value1} must be less than \texttt{value2}. The lower tick mark is \texttt{value1}. Tick marks are drawn at increments of \texttt{value3}. The last tick mark is the greatest value that does not exceed \texttt{value2}. This method of specification of tick marks is not valid for logarithmic axes. If \texttt{value3} is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

\begin{verbatim}
vaxis = 0 to 10
vaxis = 0 to 2 by .1
\end{verbatim}

VAXISLABEL=\texttt{’string’}

specifies a label for the vertical axis.

VLOWER=\texttt{value}

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies \texttt{value} as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=\texttt{value-list}

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=\texttt{’label1’,..,’labeln’}

VREFLABEL=\texttt{’label1’,..,’labeln’}

VREFLAB=\texttt{’label1’,..,’labeln’}

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=\texttt{n}

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for \texttt{n} and the corresponding label placements.

\begin{center}
\begin{tabular}{|c|l|}
\hline
\texttt{n} & label placement \\
\hline
1 & left \\
2 & right \\
\hline
\end{tabular}
\end{center}

VUPPER=\texttt{value}

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies \texttt{value} as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
**WAXIS=**\(n\)
specifies line thickness for axes and frame. The default value is 1.

**WFIT=**\(n\)
specifies line thickness for fitted curves. The default value is 1.

**WGRID=**\(n\)
specifies line thickness for grids. The default value is 1.

**WREFL=**\(n\)
specifies line thickness for reference lines. The default value is 1.

---

**CLASS Statement**

CLASS variables;

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric. If a single response variable is specified in the MODEL statement, it must also be specified in a CLASS statement.

Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in *SAS Language Reference: Dictionary*.

If the CLASS statement is used, it must appear before any of the MODEL statements.

---

**INSET Statement**

INSET <keyword-list> <options>;

The box or table of summary information produced on plots made with the \texttt{CDFPLOT}, \texttt{IPPPLOT}, \texttt{LPREDPLOT}, and \texttt{PREDPPLOT} statement is called an \textit{inset}. You can use the INSET statement to customize both the information that is printed in the inset box and the appearance of the inset box. To supply the information that is displayed in the inset box, you specify \textit{keywords} corresponding to the information you want shown. For example, the following statements produce a predicted probability plot with the number of trials, the number of events, the name of the distribution, and the estimated optimum natural threshold in the inset.

```plaintext
proc probit data=epidemic;
   model r/n = dose;
   predpplot ;
   inset nobs ntrials nevents dist optc;
run;
```

By default, inset entries are identified with appropriate labels. However, you can provide a customized label by specifying the \textit{keyword} for that entry followed by the equal sign (=) and the label in quotes. For example, the following INSET statement produces an inset containing the number of observations and the name of the distribution, labeled “Sample Size” and “Distribution” in the inset.
inset nobs='Sample Size' dist='Distribution';

If you specify a keyword that does not apply to the plot you are creating, then the keyword is ignored.

The options control the appearance of the box.

If you specify more than one INSET statement, only the first one is used.

**Keywords Used in the INSET Statement**

The following tables list keywords available in the INSET statement to display summary statistics, distribution parameters, and distribution fitting information.

**Table 60.8. Summary Statistics**

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOBS</td>
<td>number of observations</td>
</tr>
<tr>
<td>NTRIALS</td>
<td>number of trials</td>

<tr>
<td>CTEXT=color</td>
<td>specifies color for text</td>
</tr>
</tbody>
</table>

IPPPlot Statement

IPPPlot <var=variable> <options>;

The IPPPlot statement plots the inverse of the predicted probability against a single continuous variable (dose variable) in the MODEL statement for the binomial model. You can only use this statement after a binomial model statement. The confidence limits for the predicted values of the dose variable are the computed fiducial limits, not the inverse of the confidence limits of the predicted probabilities. Refer to the section “Inverse Confidence Limits” on page 3761 for more details.

VAR= (variable)

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

For the binomial model, the response variable is a probability. An estimate of the
dose level \( \hat{x}_1 \) needed for a response of \( p \) is given by

\[
\hat{x}_1 = \left( F^{-1}(p) - \mathbf{x'}_{-1} \hat{\mathbf{b}}_{-1} \right) / \hat{b}_1
\]

where \( F \) is the cumulative distribution function used to model the probability, \( \mathbf{x}_{-1} \) is the vector of the rest of the covariates, \( \hat{\mathbf{b}}_{-1} \) is the vector of the estimated parameters corresponding to \( \mathbf{x}_{-1} \), and \( \hat{b}_1 \) is the estimated parameter for the dose variable of interest.

To plot \( \hat{x}_1 \) as a function of \( p \), \( \mathbf{x}_{-1} \) must be specified. You can use the XDATA= option to provide the values of \( \mathbf{x}_{-1} \) (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

options

add features to the plot.

You can use options in the IPPPLOT statement to

- superimpose specification limits
- suppress or add the observed data points on the plot
- suppress or add the fiducial limits on the plot
- specify graphical enhancements (such as color or text height)

Summary of Options

The following tables list all options by function. The “Dictionary of Options” on page 3728 describes each option in detail.

IPP Options

</table>
### Dictionary of Options

The following entries provide detailed descriptions of the options in the IPPPLOT statement.

#### ANNOTATE=SAS-data-set

specifies an ANNOTATE data set, as described in *SAS/GRAPH Software: Reference*, that enables you to add features to the ipp plot. The ANNOTATE= data set you specify in the IPPPLOT statement is used for all plots created by the statement.

#### CAXIS=color

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

#### CFIT=color

specifies the color for the fitted ipp curves. The default is the first color in the device color list.

**Table 60.18. Options for Text Enhancement**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FONT=font</td>
<td>specifies software font for text</td>
</tr>
<tr>
<td>HEIGHT=value</td>
<td>specifies height of text used outside framed areas</td>
</tr>
<tr>
<td>INFONT=font</td>
<td>specifies software font for text inside framed areas</td>
</tr>
<tr>
<td>INHEIGHT=value</td>
<td>specifies height of text inside framed areas</td>
</tr>
</tbody>
</table>
CFRAME=color

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=color

specifies the color for grid lines. The default is the first color in the device color list.

CHREF=color

CH=color

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

CTEXT=color

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=color

CV=color

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION='string'

DES='string'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=font

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=value1 to value2<by value3>

specifies tick mark values for the horizontal axis. value1, value2, and value3 must be numeric, and value1 must be less than value2. The lower tick mark is value1. Tick marks are drawn at increments of value3. The last tick mark is the greatest value that does not exceed value2. If value3 is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

\[
\begin{align*}
\text{haxis} & = 0 \text{ to } 10 \\
\text{haxis} & = 2 \text{ to } 10 \text{ by } 2 \\
\text{haxis} & = 0 \text{ to } 200 \text{ by } 10
\end{align*}
\]

HEIGHT=value

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).
HLOWER=value
specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies value as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=value
specifies offset for horizontal axis. The default value is 1.

HUPPER=value
specifies value as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HREF < (INTERSECT) > =value-list
requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS=’label1’, . . . ,’labeln’
HREFLABEL=’label1’, . . . ,’labeln’
HREFLAB=’label1’, . . . ,’labeln’
specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS=n
specifies the vertical position of labels for HREF= lines. The following table shows valid values for n and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>top</td>
</tr>
<tr>
<td>2</td>
<td>staggered from top</td>
</tr>
<tr>
<td>3</td>
<td>bottom</td>
</tr>
<tr>
<td>4</td>
<td>staggered from bottom</td>
</tr>
<tr>
<td>5</td>
<td>alternating from top</td>
</tr>
<tr>
<td>6</td>
<td>alternating from bottom</td>
</tr>
</tbody>
</table>

INBORDER
requests a border around ipp plots.

LFIT=linetype
specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (linetype = 1) and confidence limits are drawn by connecting dashed lines (linetype = 3).
**LGRID=linetype**
specifies a line style for all grid lines. *linetype* is between 1 and 46. The default is 35.

**LHREF=linetype**
**LH=linetype**
specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

**LVREF=linetype**
**LV=linetype**
specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

**NAME=’string’**
specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is ’PROBIT’.

**NOCONF**
suppresses fiducial limits from the plot.

**NODATA**
suppresses observed data points from the plot.

**NOFIT**
suppresses the fitted ipp curves.

**NOFRAME**
suppresses the frame around plotting areas.

**NOGRID**
suppresses grid lines.

**NOHLABEL**
suppresses horizontal labels.

**NOHTICK**
suppresses horizontal tick marks.

**NOTHRESH**
suppresses the threshold line.

**NOVLABEL**
suppresses vertical labels.

**NOVTICK**
suppresses vertical tick marks.

**THRESHLABPOS=n**
specifies the vertical position of labels for the threshold line. The following table shows valid values for *n* and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>top</td>
</tr>
<tr>
<td>2</td>
<td>bottom</td>
</tr>
</tbody>
</table>
VAXIS=\textit{value1 to value2<by value3>}

specifies tick mark values for the vertical axis. \textit{value1}, \textit{value2}, and \textit{value3} must be numeric, and \textit{value1} must be less than \textit{value2}. The lower tick mark is \textit{value1}. Tick marks are drawn at increments of \textit{value3}. The last tick mark is the greatest value that does not exceed \textit{value2}. This method of specification of tick marks is not valid for logarithmic axes. If \textit{value3} is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

\begin{verbatim}
  vaxis = 0 to 10
  vaxis = 0 to 2 by .1
\end{verbatim}

\textbf{VAXISLABEL=’string’}

specifies a label for the vertical axis.

\textbf{VLOWER=\textit{value}}

specifies the lower limit on the vertical axis scale. The VLOWER= option specifies \textit{value} as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

\textbf{VREF=\textit{value-list}}

requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

\textbf{VREFLABELS=’label1’,…,’labeln’}

\textbf{VREFLABEL=’label1’,…,’labeln’}

\textbf{VREFLAB=’label1’,…,’labeln’}

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

\textbf{VREFLABPOS=n}

specifies the horizontal position of labels for VREF= lines. The following table shows valid values for \textit{n} and the corresponding label placements.

\begin{center}
\begin{tabular}{|c|c|}
\hline
\textit{n} & \textit{label placement} \\
\hline
1 & left \\
2 & right \\
\hline
\end{tabular}
\end{center}

\textbf{VUPPER=\textit{value}}

specifies the upper limit on the vertical axis scale. The VUPPER= option specifies \textit{value} as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
**LPREDPLOT Statement**

LPREDPLOT <var = variable> <options>;

The LPREDPLOT statement plots the linear predictor $x'\hat{b}$ against a single continuous variable (dose variable) in the MODEL statement for either the binomial model or the multinomial model. The confidence limits for the predicted values are only available for the binomial model.

**VAR= (variable)**

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement for which the linear predictor plot is plotted. If a `VAR=` variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

Let $x_1$ be the covariate of the dose variable, $x_{-1}$ be the vector of the rest of the covariates, $\hat{b}_{-1}$ be the vector of estimated parameters corresponding to $x_{-1}$, and $\hat{b}_1$ be the estimated parameter for the dose variable of interest.

To plot $x'\hat{b}$ as a function of $x_1$, $x_{-1}$ must be specified. You can use the XDATA= option to provide the values of $x_{-1}$ (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

**options**

add features to the plot.

For the multinomial model, you can use the LEVEL= option to specify the levels for which the linear predictor lines are plotted. The lines are labeled by the names of their levels in the middle.

You can use options in the LPREDPLOT statement to

- superimpose specification limits
• suppress or add the observed data points on the plot for the binomial model
• suppress or add the confidence limits for the binomial model
• specify the levels for which the linear predictor lines are requested for the multinomial model
• specify graphical enhancements (such as color or text height)

Summary of Options

The following tables list all options by function. The “Dictionary of Options” on page 3736 describes each option in detail.

#### Dictionary of Options

The following entries provide detailed descriptions of the options in the LPREDPLOT statement.

- **ANNOTATE=SAS-data-set**
  - specifies an ANNOTATE data set, as described in SAS/GRAPH Software: Reference, that enables you to add features to the lpred plot. The ANNOTATE= data set you specify in the LPREDPLOT statement is used for all plots created by the statement.

- **CAXIS=color**
  - **CAXES=color**
    - specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

- **CFIT=color**
  - specifies the color for the fitted lpred lines. The default is the first color in the device color list.

- **CFRAME=color**
  - **CFR=color**
    - specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

- **CGRID=color**
  - specifies the color for grid lines. The default is the first color in the device color list.

- **CHREF=color**
  - **CH=color**
    - specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.
CTEXT=\textit{color}

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=\textit{color}
CV=\textit{color}

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

\textbf{DESCRIPTION}='\textit{string}'
\textbf{DES}='\textit{string}'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

\textbf{FONT}=\textit{font}

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

\textbf{HAXIS}=\textit{value1} to \textit{value2}<by \textit{value3}>

specifies tick mark values for the horizontal axis. \textit{value1}, \textit{value2}, and \textit{value3} must be numeric, and \textit{value1} must be less than \textit{value2}. The lower tick mark is \textit{value1}. Tick marks are drawn at increments of \textit{value3}. The last tick mark is the greatest value that does not exceed \textit{value2}. If \textit{value3} is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

\begin{verbatim}
  haxis = 0 to 10
  haxis = 2 to 10 by 2
  haxis = 0 to 200 by 10
\end{verbatim}

\textbf{HEIGHT}=\textit{value}

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

\textbf{HLOWER}=\textit{value}

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies \textit{value} as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

\textbf{HOFFSET}=\textit{value}

specifies offset for horizontal axis. The default value is 1.

\textbf{HUPPER}=\textit{value}

specifies \textit{value} as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.
HREF < (INTERSECT) > = value-list
requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS= 'label1', . . . , 'labeln'
HREFLABEL= 'label1', . . . , 'labeln'
HREFLAB= 'label1', . . . , 'labeln'
specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS= n
specifies the vertical position of labels for HREF= lines. The following table shows valid values for n and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>top</td>
</tr>
<tr>
<td>2</td>
<td>staggered from top</td>
</tr>
<tr>
<td>3</td>
<td>bottom</td>
</tr>
<tr>
<td>4</td>
<td>staggered from bottom</td>
</tr>
<tr>
<td>5</td>
<td>alternating from top</td>
</tr>
<tr>
<td>6</td>
<td>alternating from bottom</td>
</tr>
</tbody>
</table>

INBORDER
requests a border around lpred plots.

LEVEL= (character-list)
ORDINAL= (character-list)
specifies the names of the levels for which linear predictor lines are requested. Names should be quoted and separated by space. If there is no correct name provided, no lpred line is plotted.

LFIT= linetype
specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (linetype = 1) and confidence limits are drawn by connecting dashed lines (linetype = 3).

LGRID= linetype
specifies a line style for all grid lines. linetype is between 1 and 46. The default is 35.

LHREF= linetype
LH= linetype
specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.
**LPREDPLOT Statement**

L VREF=`linetype`

L V=`linetype`

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME=`string`

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'PROBIT'.

NOCONF

suppresses confidence limits from the plot. This only works for the binomial model. Confidence limits are not plotted for the multinomial model.

NODATA

suppresses observed data points from the plot. This only works for the binomial model. Data points are not plotted for the multinomial model.

NOFIT

suppresses the fitted lpred lines.

NOFRAME

suppresses the frame around plotting areas.

NOGRID

suppresses grid lines.

NOHLABEL

suppresses horizontal labels.

NOHTICK

suppresses horizontal tick marks.

NOTHRESH

suppresses the threshold line.

NOVLABEL

suppresses vertical labels.

NOVTICK

suppresses vertical tick marks.

THRESHLABPOS=`n`

specifies the horizontal position of labels for the threshold line. The following table shows valid values for `n` and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>left</td>
</tr>
<tr>
<td>2</td>
<td>right</td>
</tr>
</tbody>
</table>
VAXIS=\texttt{value1 to value2<by value3>}
specifies tick mark values for the vertical axis. \texttt{value1}, \texttt{value2}, and \texttt{value3} must be numeric, and \texttt{value1} must be less than \texttt{value2}. The lower tick mark is \texttt{value1}. Tick marks are drawn at increments of \texttt{value3}. The last tick mark is the greatest value that does not exceed \texttt{value2}. This method of specification of tick marks is not valid for logarithmic axes. If \texttt{value3} is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

\begin{verbatim}
  vaxis = 0 to 10
  vaxis = 0 to 2 by .1
\end{verbatim}

VAXISLABEL=’string’
specifies a label for the vertical axis.

VLOWER=value
specifies the lower limit on the vertical axis scale. The VLOWER= option specifies \texttt{value} as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=value-list
requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=’label1’,\ldots,’labeln’

VREFLABEL=’label1’,\ldots,’labeln’

VREFLAB=’label1’,\ldots,’labeln’
specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=\texttt{n}
specifies the horizontal position of labels for VREF= lines. The following table shows valid values for \texttt{n} and the corresponding label placements.

\begin{center}
\begin{tabular}{|c|l|}
\hline
\texttt{n} & label placement \\
\hline
1 & left \\
2 & right \\
\hline
\end{tabular}
\end{center}

VUPPER=number
specifies the upper limit on the vertical axis scale. The VUPPER= option specifies \texttt{number} as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
WAXIS=\text{n}

specifies line thickness for axes and frame. The default value is 1.

WFIT=\text{n}

specifies line thickness for fitted lines. The default value is 1.

WGRID=\text{n}

specifies line thickness for grids. The default value is 1.

WREFL=\text{n}

specifies line thickness for reference lines. The default value is 1.

**MODEL Statement**

\[
<\text{label:}> \quad \text{MODEL} \quad \text{response}=\text{effects} \quad <\quad \text{/ options} \quad >; \\
<\text{label:}> \quad \text{MODEL} \quad \text{events/trials}=\text{effects} \quad <\quad \text{/ options} \quad >; 
\]

The MODEL statement names the variables used as the response and the independent variables. Additionally, you can specify the distribution used to model the response, as well as other options. Only a single MODEL statement can be used with one invocation of the PROBIT procedure. If multiple MODEL statements are present, only the last is used. Main effects and interaction terms can be specified in the MODEL statement, similar to the GLM procedure.

The optional \textit{label} is used to label output from the matching MODEL statement.

The \textit{response} can be a single variable with a value that is used to indicate the level of the observed response. Such a response variable must be listed in the \texttt{CLASS} statement. For example, the response might be a variable called \texttt{Symptoms} that takes on the values ‘None,’ ‘Mild,’ or ‘Severe.’ Note that, for dichotomous response variables, the probability of the lower sorted value is modeled by default (see the “Details” section beginning on page 3754). Because the model fit by the PROBIT procedure requires ordered response levels, you may need to use either the \texttt{ORDER=DATA} option in the \texttt{PROC PROBIT} statement or a numeric coding of the response to get the desired ordering of levels.

Alternatively, the response can be specified as a pair of variable names separated by a slash (/). The value of the first variable, \texttt{events}, is the number of positive responses (or events). The value of the second variable, \texttt{trials}, is the number of trials. Both variables must be numeric and non-negative, and the ratio of the first variable value to the second variable value must be between 0 and 1, inclusive. For example, the variables might be \texttt{hits}, a variable containing the number of hits for a baseball player, and \texttt{AtBats}, a variable containing the number of times at bat. A model for hitting proportion (batting average) as a function of age could be specified as

\[
\text{model hits/AtBats=age;}
\]

The \textit{effects} following the equal sign are the covariates in the model. Higher-order effects, such as interactions and nested terms, are allowed in the list, similar to the GLM procedure. Variable names and combinations of variable names representing
higher-order terms are allowed to appear in this list. Class variables can be used as
effects, and indicator variables are generated for the class levels. If you do not specify
any covariates following the equal sign, an intercept-only model is fit.

The following options are available in the MODEL statement.

**AGGREGATE**

*AGGREGATE* = *(variable-list)*

specifies the subpopulations on which the Pearson chi-square test statistic and the
log-likelihood ratio chi-square test statistic (deviance) are calculated if the LACKFIT
option is specified. See the section "Rescaling the Covariance Matrix" on page 3760
for details of Pearson’s chi-square and deviance calculations.

Observations with common values in the given list of variables are regarded as com-
ing from the same subpopulation. Variables in the list can be any variables in the
input data set. Specifying the AGGREGATE option is equivalent to specifying the
AGGREGATE= option with a variable list that includes all independent variables in
the MODEL statement. The PROBIT procedure sorts the input data set according to
the variables specified in this list. Information for the sorted data set is reported in
the “Response-Covariate Profile” table.

The deviance and Pearson goodness-of-fit statistics are calculated if the LACKFIT
option is specified in the MODEL statement. The calculated results are reported in
the “Goodness-of-Fit” table. If the Pearson chi-square test is significant with the
test level specified by the HPROB= option, the fiducial limits, if required with the
INVERSECL option in the MODEL statement, are modified (see the section “Inverse
Confidence Limits” on page 3761 for details). Also, the covariance matrix is re-scaled
by the dispersion parameter when the SCALE= option is specified.

**ALPHA** = *value*

sets the significance level for the confidence intervals for regression parameters, fidu-
cial limits for the predicted values, and confidence intervals for the predicted proba-
bilities. The value must be between 0 and 1. The default value is ALPHA=0.05.

**CONVERGE** = *value*

specifies the convergence criterion. Convergence is declared when the maximum
change in the parameter estimates between Newton-Raphson steps is less than the
value specified. The change is a relative change if the parameter is greater than 0.01
in absolute value; otherwise, it is an absolute change.

By default, CONVERGE=1.0E-8.

**CORRB**

displays the estimated correlation matrix of the parameter estimates.

**COVB**

displays the estimated covariance matrix of the parameter estimates.

**DISTRIBUTION** = *distribution-type*

**DIST** = *distribution-type*

**D** = *distribution-type*

specifies the cumulative distribution function used to model the response probabili-

ties. The distributions are described in the “Details” section beginning on page 3754. Valid values for distribution-type are

NORMAL the normal distribution for the probit model
LOGISTIC the logistic distribution for the logit model
EXTREME VALUE | EXTREME | GOMPERTZ the extreme value, or Gompertz
distribution for the gompit model

By default, DISTRIBUTION=NORMAL.

**HPROB=p**
specifies a minimum probability level for the Pearson chi-square to indicate a good fit. The default value is 0.10. The LACKFIT option must also be specified for this option to have any effect. For Pearson goodness-of-fit chi-square values with probability greater than the HPROB= value, the fiducial limits, if requested with the INVERSECL option, are computed using a critical value of 1.96. For chi-square values with probability less than the value of the HPROB= option, the critical value is a 0.95 two-sided quantile value taken from the t distribution with degrees of freedom equal to \((k - 1) \times m - q\), where \(k\) is the number of levels for the response variable, \(m\) is the number of different sets of independent variable values, and \(q\) is the number of parameters fit in the model. If you specify the HPROB= option in both the PROC PROBIT and MODEL statements, the MODEL statement option takes precedence.

**INITIAL=values**
sets initial values for the parameters in the model other than the intercept. The values must be given in the order in which the variables are listed in the MODEL statement. If some of the independent variables listed in the MODEL statement are classification variables, then there must be as many values given for that variable as there are classification levels minus 1. The INITIAL option can be specified as follows.

<table>
<thead>
<tr>
<th>Type of List</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>list separated by blanks</td>
<td>initial=3 4 5</td>
</tr>
<tr>
<td>list separated by commas</td>
<td>initial=3,4,5</td>
</tr>
</tbody>
</table>

By default, all parameters have initial estimates of zero.

**Note:** The INITIAL= option is overwritten by the INEST= option in the PROC PROBIT statement.

**INTERCEPT=value**
initializes the intercept parameter to value. By default, INTERCEPT=0.

**INVERSECL**
computes confidence limits for the values of the first continuous independent variable (such as dose) that yield selected response rates. If the algorithm fails to converge (this can happen when \(C\) is nonzero), missing values are reported for the confidence limits. See the section “Inverse Confidence Limits” on page 3761 for details.
ITPRINT displays the iteration history, the final evaluation of the gradient, and the second derivative matrix (Hessian).

LACKFIT performs two goodness-of-fit tests (a Pearson chi-square test and a log-likelihood ratio chi-square test) for the fitted model.

To compute the test statistics, proper grouping of the observations into subpopulations is needed. You can use the AGGREGATE or AGGREGATE= option to this end. See the entry for the AGGREGATE and AGGREGATE= options under the MODEL statement. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the events/trials syntax.

Note: This test is not appropriate if the data are very sparse, with only a few values at each set of the independent variable values.

If the Pearson chi-square test statistic is significant, then the covariance estimates and standard error estimates are adjusted. See the section “Lack of Fit Tests” on page 3759 for a description of the tests. Note that the LACKFIT option can also appear in the PROC PROBIT statement. See the section “PROC PROBIT Statement” on page 3711 for details.

MAXITER=value

MAXIT=value

specifies the maximum number of iterations to be performed in estimating the parameters. By default, MAXITER=50.

NOINT fits a model with no intercept parameter. If the INTERCEPT= option is also specified, the intercept is fixed at the specified value; otherwise, it is set to zero. This is most useful when the response is binary. When the response has $k$ levels, then $k - 1$ intercept parameters are fit. The NOINT option sets the intercept parameter corresponding to the lowest response level equal to zero. A Lagrange multiplier, or score, test for the restricted model is computed when the NOINT option is specified.

SCALE= scale

enables you to specify the method for estimating the dispersion parameter. To correct for overdispersion or underdispersion, the covariance matrix is multiplied by the estimate of the dispersion parameter. Valid values for scale are as follows:

D | DEVIANCE specifies that the dispersion parameter be estimated by the deviance divided by its degrees of freedom.

P | PEARSON specifies that the dispersion parameter be estimated by the Pearson chi-square statistic divided by its degrees of freedom. This is set as the default.

You can use the AGGREGATE= option to define the subpopulations for calculating the Pearson chi-square statistic and the deviance.
The “Goodness-of-Fit ” table includes the Pearson chi-square statistic, the deviance, their degrees of freedom, the ratio of each statistic divided by its degrees of freedom, and the corresponding \( p \)-value.

**SINGULAR=value**
specifies the singularity criterion for determining linear dependencies in the set of independent variables. The sum of squares and cross-products matrix of the independent variables is formed and swept. If the relative size of a pivot becomes less than the value specified, then the variable corresponding to the pivot is considered to be linearly dependent on the previous set of variables considered. By default, SINGULAR=1E−12.

**OUTPUT Statement**

```sas
OUTPUT <OUT=SAS-data-set> <keyword=name . . .keyword=name>;
```

The OUTPUT statement creates a new SAS data set containing all variables in the input data set and, optionally, the fitted probabilities, the estimate of \( \mathbf{x}'\beta \), and the estimate of its standard error. Estimates of the probabilities, \( \mathbf{x}'\beta \), and the standard errors are computed for observations with missing response values as long as the values of all the explanatory variables are nonmissing. This enables you to compute these statistics for additional settings of the explanatory variables that are of interest but for which responses are not observed.

You can specify multiple OUTPUT statements. Each OUTPUT statement creates a new data set and applies only to the preceding MODEL statement. If you want to create a permanent SAS data set, you must specify a two-level name (refer to SAS Language Reference: Concepts for more information on permanent SAS data sets).

Details on the specifications in the OUTPUT statement are as follows:

- **keyword=name** specifies the statistics to include in the output data set and assigns names to the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

- **PROB | P** cumulative probability estimates
  \[
p = C + (1 - C)F(a_j + \mathbf{x}'\beta)
\]
- **STD** standard error estimates of \( a_j + \mathbf{x}'\beta \)
- **XBETA** estimates of \( a_j + \mathbf{x}'\beta \)

- **OUT=SAS-data-set** names the output data set. By default, the new data set is named using the DATA\( n \) convention.
When the single variable response syntax is used, the _LEVEL_ variable is added to the output data set, and there are \( k - 1 \) output observations for each input observation, where \( k \) is the number of response levels. There is no observation output corresponding to the highest response level. For each of the \( k - 1 \) observations, the PROB variable contains the fitted probability of obtaining a response level up to the level indicated by the _LEVEL_ variable, the XBETA variable contains \( a_j + x'\hat{b} \), where \( j \) references the levels \((a_1 = 0)\), and the STD variable contains the standard error estimate of the XBETA variable. See the “Details” section, which follows, for the formulas for the parameterizations.

**PREDPLOT Statement**

```
PREDPLOT <var = variable> <options>;
```

The PREDPLOT statement plots the predicted probability against a single continuous variable (dose variable) in the MODEL statement for both the binomial model and the multinomial model. Confidence limits are only available for the binomial model. An attached box on the right side of the plot is used to label predicted probability curves with the names of their levels for the multinomial model. You can specify the color of this box using the CLABBOX= option.

**VAR= (variable)**

specifies a single continuous variable (dose variable) in the independent variable list of the MODEL statement. If a VAR= variable is not specified, the first single continuous variable in the independent variable list of the MODEL statement is used. If such a variable does not exist in the independent variable list of the MODEL statement, an error is reported.

The predicted probability is

\[
\hat{p} = C + (1 - C)F(x'\hat{b})
\]

for the binomial model and

\[
\begin{align*}
\hat{p}_1 &= C + (1 - C)F(x'\hat{b}) \\
\hat{p}_j &= (1 - C)(F(\hat{a}_j + x'\hat{b}) - F(\hat{a}_{j-1} + x'\hat{b})) \quad j = 2, \ldots, k - 1 \\
\hat{p}_k &= (1 - C)(1 - F(\hat{a}_{k-1} + x'\hat{b}))
\end{align*}
\]

for the multinomial model with \( k \) response levels, where \( F \) is the cumulative distribution function used to model the probability, \( x' \) is the vector of the covariates, \( \hat{a}_j \) are the estimated ordinal intercepts with \( \hat{a}_1 = 0 \), \( C \) is the threshold parameter, either known or estimated from the model, and \( \hat{b}' \) is the vector of estimated parameters.

To plot \( \hat{p} \) (or \( \hat{p}_j \)) as a function of a continuous variable \( x_1 \), the remaining covariates \( x_{-1} \) must be specified. You can use the XDATA= option to provide the values of \( x_{-1} \) (see the XDATA= option in the PROC PROBIT statement for details), or use the default values that follow the rules:
• If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
• If the effect is a single classification variable, the highest level of the variable is used.

**options**

enable you to plot the observed data and add features to the plot.

You can use options in the PREDPPLOT statement to

• superimpose specification limits
• suppress or add observed data points for the binomial model
• suppress or add confidence limits for the binomial model
• specify the levels for which predicted probability curves are requested for the multinomial model
• specify graphical enhancements (such as color or text height)

**Summary of Options**

The following tables list all *options* by function. The “Dictionary of Options” on page 3749 describes each option in detail.

**PREDPLOT Options**

**Table 60.26.** Plot Layout Options for PREDPLOT

<table>
<thead>

Dictionary of Options

The following entries provide detailed descriptions of the options in the PREDPPLLOT statement.

ANNOTATE=SAS-data-set
ANNO=SAS-data-set
specifies an ANNOTATE data set, as described in SAS/GRAPH Software: Reference, that enables you to add features to the predicted probability plot. The ANNOTATE= data set you specify in the PREDPPLLOT statement is used for all plots created by the statement.

CAXIS=color
CAXES=color
specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

CFIT=color
specifies the color for the fitted predicted probability curves. The default is the first color in the device color list.

CFRAME=color
CFR=color
specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

CGRID=color
specifies the color for grid lines. The default is the first color in the device color list.

CHREF=color
CH=color
specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.
CTEXT=\texttt{color}

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

CVREF=\texttt{color}
CV=\texttt{color}

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

DESCRIPTION=’\texttt{string}’
DES=’\texttt{string}’

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

FONT=\texttt{font}

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

HAXIS=\texttt{value1 to value2 by value3}

specifies tick mark values for the horizontal axis. \texttt{value1}, \texttt{value2}, and \texttt{value3} must be numeric, and \texttt{value1} must be less than \texttt{value2}. The lower tick mark is \texttt{value1}. Tick marks are drawn at increments of \texttt{value3}. The last tick mark is the greatest value that does not exceed \texttt{value2}. If \texttt{value3} is omitted, a value of 1 is used.

Examples of HAXIS= lists are:

\begin{verbatim}
  haxis = 0 to 10
  haxis = 2 to 10 by 2
  haxis = 0 to 200 by 10
\end{verbatim}

HEIGHT=\texttt{value}

specifies the height of text used outside framed areas.

HLOWER=\texttt{value}

specifies the lower limit on the horizontal axis scale. The HLOWER= option specifies \texttt{value} as the lower horizontal axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the HAXIS= option is used.

HOFFSET=\texttt{value}

specifies the offset for the horizontal axis. The default value is 1.

HUPPER=\texttt{value}

specifies \texttt{value} as the upper horizontal axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the HAXIS= option is used.
HREF < (INTERSECT) > = value-list
requests reference lines perpendicular to the horizontal axis. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

HREFLABELS= 'label1', . . . , 'labeln'
HREFLABEL= 'label1', . . . , 'labeln'
HREFLAB= 'label1', . . . , 'labeln'
specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

HREFLABPOS= n
specifies the vertical position of labels for HREF= lines. The following table shows valid values for n and the corresponding label placements.

<table>
<thead>
<tr>
<th>n</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>alternating from top</td>
</tr>
<tr>
<td>6</td>
<td>alternating from bottom</td>
</tr>
</tbody>
</table>

INBORDER
requests a border around predicted probability plots.

LEVEL= (character-list)
ORDINAL= (character-list)
specifies the names of the levels for which predicted probability curves are requested. Names should be quoted and separated by space. If there is no correct name provided, no fitted probability curve is plotted.

LFIT= linetype
specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (linetype = 1) and confidence limits are drawn by connecting dashed lines (linetype = 3).

LGRID= linetype
specifies a line style for all grid lines. linetype is between 1 and 46. The default is 35.

LHREF= linetype
LH= linetype
specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.
LVREF= **linetype**
LV= **linetype**
specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

NAME= ‘**string**’
specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is ‘PROBIT’.

**NOCONF**
suppresses confidence limits from the plot. This only works for the binomial model. Confidence limits are not plotted for the multinomial model.

**NODATA**
suppresses observed data points from the plot. This only works for the binomial model. The data points are not plotted for the multinomial model.

**NOFIT**
suppresses the fitted predicted probability curves.

**NOFRAME**
suppresses the frame around plotting areas.

**NOGRID**
suppresses grid lines.

**NOHLABEL**
suppresses horizontal labels.

**NOHTICK**
suppresses horizontal tick marks.

**NOTHRESH**
suppresses the threshold line.

**NOVLABEL**
suppresses vertical labels.

**NOVTICK**
suppresses vertical tick marks.

**THRESHLABPOS=** **n**
specifies the horizontal position of labels for the threshold line. The following table shows valid values for **n** and the corresponding label placements.

<table>
<thead>
<tr>
<th><strong>n</strong></th>
<th><strong>label placement</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>left</td>
</tr>
<tr>
<td>2</td>
<td>right</td>
</tr>
</tbody>
</table>
VAXIS=\textit{value1 to value2<by value3>}
specifies tick mark values for the vertical axis. \textit{value1, value2}, and \textit{value3} must be numeric, and \textit{value1} must be less than \textit{value2}. The lower tick mark is \textit{value1}. Tick marks are drawn at increments of \textit{value3}. The last tick mark is the greatest value that does not exceed \textit{value2}. This method of specification of tick marks is not valid for logarithmic axes. If \textit{value3} is omitted, a value of 1 is used.

Examples of VAXIS= lists are:

\begin{verbatim}
  vaxis = 0 to 10
  vaxis = 0 to 2 by .1
\end{verbatim}

VAXISLABEL=\textit{string}
specifies a label for the vertical axis.

VLOWER=\textit{value}
specifies the lower limit on the vertical axis scale. The VLOWER= option specifies \textit{value} as the lower vertical axis tick mark. The tick mark interval and the upper axis limit are determined automatically. This option has no effect if the VAXIS= option is used.

VREF=\textit{value-list}
requests reference lines perpendicular to the vertical axis. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

VREFLABELS=\textit{label1’,…,’labeln’}
VREFLABEL=\textit{label1’,…,’labeln’}
VREFLAB=\textit{label1’,…,’labeln’}
specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

VREFLABPOS=\textit{n}
specifies the horizontal position of labels for VREF= lines. The following table shows valid values for \textit{n} and the corresponding label placements.

<table>
<thead>
<tr>
<th>\textit{n}</th>
<th>label placement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>left</td>
</tr>
<tr>
<td>2</td>
<td>right</td>
</tr>
</tbody>
</table>

VUPPER=\textit{value}
specifies the upper limit on the vertical axis scale. The VUPPER= option specifies \textit{value} as the upper vertical axis tick mark. The tick mark interval and the lower axis limit are determined automatically. This option has no effect if the VAXIS= option is used.
**WAXIS=**
specifies line thickness for axes and frame. The default value is 1.

**WFIT=**
specifies line thickness for fitted curves. The default value is 1.

**WGRID=**
specifies line thickness for grids. The default value is 1.

**WREFL=**
specifies line thickness for reference lines. The default value is 1.

---

**WEIGHT Statement**

```
WEIGHT variable;
```

A WEIGHT statement can be used with PROC PROBIT to weight each observation by the value of the variable specified. The contribution of each observation to the likelihood function is multiplied by the value of the weight variable. Observations with zero, negative, or missing weights are not used in model estimation.

---

**Details**

**Missing Values**

PROC PROBIT does not use any observations having missing values for any of the independent variables, the response variables, or the weight variable. If only the response variables are missing, statistics requested in the OUTPUT statement are computed.

**Response Level Ordering**

For binary response data, PROC PROBIT fits the following model by default,

\[ \Phi^{-1} \left( \frac{p - C}{1 - C} \right) = \mathbf{x}' \mathbf{\beta} \]

where \( p \) is the probability of the response level identified as the first level in the “Weighted Frequency Counts for the Ordered Response Categories” table in the output and \( \Phi \) is the normal cumulative distribution function. By default, the covariate vector \( \mathbf{x} \) contains an intercept term. This is sometimes called Abbot’s formula.

Because of the symmetry of the normal (and logistic) distribution, the effect of reversing the order of the two response values is to change the signs of \( \mathbf{\beta} \) in the preceding equation.

By default, response levels appear in ascending, sorted order (that is, the lowest level appears first and then the next lowest, and so on). There are a number of ways that you can control the sort order of the response categories and, therefore, which level is assigned the first ordered level. One of the most common sets of response levels is \{0,1\}, with 1 representing the event with the probability that is to be modeled.
Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and EXPOSURE is the explanatory variable. By default, PROC PROBIT assigns the first ordered level to response level 0, causing the probability of the nonevent to be modeled. There are several ways to change this.

Besides recoding the variable Y, you can

- assign a format to Y such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. For this example, Y=0 could be assigned formatted value ‘nonevent’ and Y=1 could be assigned formatted value ‘event.’ Since ORDER=FORMATTED by default, Y=1 becomes the first ordered level. See Example 60.3 for an illustration of this method.

```plaintext
proc format;
   value disease 1='event' 0='nonevent';
run;
proc probit;
   model y=exposure;
   format y disease.;
run;
```

- arrange the input data set so that Y=1 appears first and use the ORDER=DATA option in the PROC PROBIT statement. Since ORDER=DATA sorts levels in order of their appearance in the data set, Y=1 becomes the first ordered level. Note that this option causes class variables to be sorted by their order of appearance in the data set, also.

---

**Computational Method**

The log-likelihood function is maximized by means of a ridge-stabilized Newton-Raphson algorithm. Initial regression parameter estimates are set to zero. The INITIAL= and INTERCEPT= options in the MODEL statement can be used to give nonzero initial estimates.

The log-likelihood function, \( L \), is computed as

\[
L = \sum_i w_i \ln(p_i)
\]

where the sum is over the observations in the data set, \( w_i \) is the weight for the \( i \)th observation, and \( p_i \) is the modeled probability of the observed response. In the case of the events/trials syntax in the MODEL statement, each observation contributes two terms corresponding to the probability of the event and the probability of its complement:

\[
L = \sum_i w_i [r_i \ln(p_i) + (n_i - r_i) \ln(1 - p_i)]
\]

where \( r_i \) is the number of events and \( n_i \) is the number of trials for observation \( i \). This log-likelihood function differs from the log-likelihood function for a binomial
or multinomial distribution by additive terms consisting of the log of binomial or multinomial coefficients. These terms are parameter-independent and do not affect the model estimation or the standard errors and tests.

The estimated covariance matrix, $V$, of the parameter estimates is computed as the negative inverse of the information matrix of second derivatives of $L$ with respect to the parameters evaluated at the final parameter estimates. Thus, the estimated covariance matrix is derived from the observed information matrix rather than the expected information matrix (these are generally not the same). The standard error estimates for the parameter estimates are taken as the square roots of the corresponding diagonal elements of $V$.

If convergence of the maximum likelihood estimates is attained, a Type III chi-square test statistic is computed for each effect, testing whether there is any contribution from any of the levels of the effect. This statistic is computed as a quadratic form in the appropriate parameter estimates using the corresponding submatrix of the asymptotic covariance matrix estimate. Refer to Chapter 32, “The GLM Procedure,” and Chapter 11, “The Four Types of Estimable Functions,” for more information about Type III estimable functions.

The asymptotic covariance matrix is computed as the inverse of the observed information matrix. Note that if the NOINT option is specified and class variables are used, the first class variable contains a contribution from an intercept term. The results are displayed in an ODS table named Type3Analysis.

Chi-square tests for individual parameters are Wald tests based on the observed information matrix and the parameter estimates. If an effect has a single degree of freedom in the parameter estimates table, the chi-square test for this parameter is equivalent to the Type III test for this effect.

In releases previous to Version 8.2, a multiple degree of freedom statistic was computed for each effect to test for contribution from any level of the effect. In general, the Type III test statistic in a main effect only model (no interaction terms) will be equal to the previously computed effect statistic, unless there are collinearities among the effects. If there are collinearities, the Type III statistic will adjust for them, and the value of the Type III statistic and the number of degrees of freedom might not be equal to those of the previous effect statistic.

The theory behind these tests assumes large samples. If the samples are not large, it may be better to base the tests on log-likelihood ratios. These changes in log likelihood can be obtained by fitting the model twice, once with all the parameters of interest and once leaving out the parameters to be tested. Refer to Cox and Oakes (1984) for a discussion of the merits of some possible test methods.

If some of the independent variables are perfectly correlated with the response pattern, then the theoretical parameter estimates may be infinite. Although fitted probabilities of 0 and 1 are not especially pathological, infinite parameter estimates are required to yield these probabilities. Due to the finite precision of computer arithmetic, the actual parameter estimates are not infinite. Indeed, since the tails of the distributions allowed in the PROBIT procedure become small rapidly, an argument to the cumulative distribution function of around 20 becomes effectively infinite. In the
case of such parameter estimates, the standard error estimates and the corresponding chi-square tests are not trustworthy.

### Distributions

The distributions, $F(x)$, allowed in the PROBIT procedure are specified with the DISTRIBUTION= option in the model statement. The cumulative distribution functions for the available distributions are

\[
\int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp \left( -\frac{z^2}{2} \right) \, dz \text{ (normal)}
\]

\[
\frac{1}{1 + e^{-x}} \text{ (logistic)}
\]

\[
1 - e^{-e^x} \text{ (extreme value or Gompertz)}
\]

The variances of these three distributions are not all equal to 1, and their means are not all equal to zero. Their means and variances are shown in the following table, where $\gamma$ is the Euler constant.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Mean</th>
<th>Variance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Logistic</td>
<td>0</td>
<td>$\pi^2/3$</td>
</tr>
<tr>
<td>extreme value or Gompertz</td>
<td>$-\gamma$</td>
<td>$\pi^2/6$</td>
</tr>
</tbody>
</table>

When comparing parameter estimates using different distributions, you need to take into account the different scalings and, for the extreme value (or Gompertz) distribution, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from the logistic model should be about $\pi/\sqrt{3}$ larger than the estimates from the probit model.

### INEST= SAS-data-set

The INEST= data set names a SAS data set that specifies initial estimates for all the parameters in the model.

The INEST= data set must contain the intercept variables (named Intercept for binary response model and Intercept, Intercept2, Intercept3, and so forth, for multinomial response models) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value ‘PARMS’ are used as starting values. Combining the INEST= data...
set and the option MAXIT= in the MODEL statement, partial scoring can be done, such as predicting on a validation data set by using the model built from a training data set.

You can specify starting values for the iterative algorithm in the INEST= data set. This data set overwrites the INITIAL= option in the MODEL statement, which is a little difficult to use for models with multilevel interaction effects. The INEST= data set has the same structure as the “OUTEST= SAS-data-set” on page 3762, but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

Model Specification

For a two-level response, the probability that the lesser response occurs is modeled by the probit equation as

\[ p = C + (1 - C)F(x'b) \]

The probability of the other (complementary) event is \( 1 - p \).

For a multilevel response with outcomes labeled \( l_i \) for \( i = 1, 2, \ldots, k \), the probability, \( p_j \), of observing level \( l_j \) is as follows.

\[ p_1 = C + (1 - C)F(x'b) \]
\[ p_2 = (1 - C)\left( F(a_2 + x'b) - F(x'b) \right) \]
\[ \vdots \]
\[ p_j = (1 - C)\left( F(a_j + x'b) - F(a_{j-1} + x'b) \right) \]
\[ \vdots \]
\[ p_k = (1 - C)(1 - F(a_{k-1} + x'b)) \]

Thus, for a \( k \)-level response, there are \( k - 2 \) additional parameters, \( a_2, a_3, \ldots, a_{k-1} \), estimated. These parameters are denoted by Intercept\( j, j = 2, 3, \ldots, k - 1 \) in the output.

An intercept parameter is always added to the set of independent variables as the first term in the model unless the NOINT option is specified in the MODEL statement. If a classification variable taking on \( k \) levels is used as one of the independent variables, a set of \( k \) indicator variables is generated to model the effect of this variable. Because of the presence of the intercept term, there are at most \( k - 1 \) degrees of freedom for this effect in the model.
Lack of Fit Tests

Two goodness-of-fit tests can be requested from the PROBIT procedure: a Pearson chi-square test and a log-likelihood ratio chi-square test.

To compute the test statistics, you can use the AGGREGATE or AGGREGATE= option grouping the observations into subpopulations. If neither AGGREGATE nor AGGREGATE= is specified, PROC PROBIT assumes that each observation is from a separate subpopulation and computes the goodness-of-fit test statistics only for the events/trials syntax.

If the Pearson goodness-of-fit chi-square test is requested and the p-value for the test is too small, variances and covariances are adjusted by a heterogeneity factor (the goodness-of-fit chi-square divided by its degrees of freedom) and a critical value from the $t$ distribution is used to compute the fiducial limits. The Pearson chi-square test statistic is computed as

$$\chi^2_P = \sum_{i=1}^{m} \sum_{j=1}^{k} \frac{(r_{ij} - n_i \hat{p}_{ij})^2}{n_i \hat{p}_{ij}}$$

where the sum on $i$ is over grouping, the sum on $j$ is over levels of response, the $r_{ij}$ is the frequency of response level $j$ for the $i$th grouping, $n_i$ is the total frequency for the $i$th grouping, and $\hat{p}_{ij}$ is the fitted probability for the $j$th level at the $i$th grouping.

The likelihood ratio chi-square test statistic is computed as

$$\chi^2_D = 2 \sum_{i=1}^{m} \sum_{j=1}^{k} r_{ij} \ln \left( \frac{r_{ij}}{n_i \hat{p}_{ij}} \right)$$

This quantity is sometimes called the deviance. If the modeled probabilities fit the data, these statistics should be approximately distributed as chi-square with degrees of freedom equal to $(k-1) \times m - q$, where $k$ is the number of levels of the multinomial or binomial response, $m$ is the number of sets of independent variable values (covariate patterns), and $q$ is the number of parameters fit in the model.

In order for the Pearson statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the groupings. When this is not true, the data are sparse, and the $p$-values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson statistic and the deviance provides some evidence that the data are too sparse to use either statistic.
Rescaling the Covariance Matrix

One way of correcting overdispersion is to multiply the covariance matrix by a dispersion parameter. You can supply the value of the dispersion parameter directly, or you can estimate the dispersion parameter based on either the Pearson chi-square statistic or the deviance for the fitted model.

The Pearson chi-square statistic \( \chi^2_P \) and the deviance \( \chi^2_D \) are defined in the section “Lack of Fit Tests” on page 3759. If the SCALE= option is specified in the MODEL statement, the dispersion parameter is estimated by

\[
\hat{\sigma}^2 = \begin{cases} 
\frac{\chi^2_P}{m(k - 1) - q} & \text{SCALE=PEARSON} \\
\frac{\chi^2_D}{m(k - 1) - q} & \text{SCALE=DEVIANCE} \\
(constant)^2 & \text{SCALE=constant}
\end{cases}
\]

In order for the Pearson statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the subpopulations. When this is not true, the data are sparse, and the \( p \)-values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

You can use the AGGREGATE (or AGGREGATE=) option to define the subpopulation profiles. If you do not specify this option, each observation is regarded as coming from a separate subpopulation. For events/trials syntax, each observation represents \( n \) Bernoulli trials, where \( n \) is the value of the trials variable; for single-trial syntax, each observation represents a single trial. Without the AGGREGATE (or AGGREGATE=) option, the Pearson chi-square statistic and the deviance are calculated only for events/trials syntax.

Note that the parameter estimates are not changed by this method. However, their standard errors are adjusted for overdispersion, affecting their significance tests.

Tolerance Distribution

For a single independent variable, such as a dosage level, the models for the probabilities can be justified on the basis of a population with mean \( \mu \) and scale parameter \( \sigma \) of tolerances for the subjects. Then, given a dose \( x \), the probability, \( P \), of observing a response in a particular subject is the probability that the subject’s tolerance is less than the dose or

\[
P = F \left( \frac{x - \mu}{\sigma} \right)
\]

Thus, in this case, the intercept parameter, \( b_0 \), and the regression parameter, \( b_1 \), are related to \( \mu \) and \( \sigma \) by

\[
b_1 = \frac{1}{\sigma}
\]
Note: The parameter $\sigma$ is not equal to the standard deviation of the population of tolerances for the logistic and extreme value distributions.

Inverse Confidence Limits

In bioassay problems, estimates of the values of the independent variables that yield a desired response are often needed. For instance, the value yielding a 50% response rate (called the ED50 or LD50) is often used. The INVERSECL option requests that confidence limits be computed for the value of the independent variable that yields a specified response. These limits are computed only for the first continuous variable effect in the model. The other variables are set either at their mean values if they are continuous or at the reference (last) level if they are discrete variables. For a discussion of inverse confidence limits, refer to Hubert, Bohidar, and Peace (1988).

For the PROBIT procedure, the response variable is a probability. An estimate of the first continuous variable value needed to achieve a response of $p$ is given by

$$
\hat{x}_1 = \frac{1}{b_1} \left( F^{-1}(p) - x^* b^* \right)
$$

where $F$ is the cumulative distribution function used to model the probability, $x^*$ is the vector of independent variables excluding the first one, which can be specified by the XDATAL= option described in the section “XDATAL= SAS-data-set” on page 3763, $b^*$ is the vector of parameter estimates excluding the first one, and $b_1$ is the estimated regression coefficient for the independent variable of interest. Note that, for both binary and ordinal models, the INVERSECL option provides estimates of the value of $x_1$ yielding $\Pr(\text{first response level}) = p$, for various values of $p$.

This estimator is given as a ratio of random variables, for example, $r = a/b$. Confidence limits for this ratio can be computed using Fieller’s theorem. A brief description of this theorem follows. Refer to Finney (1971) for a more complete description of Fieller’s theorem.

If the random variables $a$ and $b$ are thought to be distributed as jointly normal, then for any fixed value $r$ the following probability statement holds if $z$ is an $\alpha/2$ quantile from the standard normal distribution and $\mathbf{V}$ is the variance-covariance matrix of $a$ and $b$.

$$
\Pr \left( (a - rb)^2 > z^2(V_{aa} - 2rV_{ab} + r^2V_{bb}) \right) = \alpha
$$

Usually the inequality can be solved for $r$ to yield a confidence interval. The PROBIT procedure uses a value of 1.96 for $z$, corresponding to an $\alpha$ value of 0.05, unless the goodness-of-fit $p$-value is less than the specified value of the HPROB= option. When this happens, the covariance matrix is scaled by the heterogeneity factor, and a $t$ distribution quantile is used for $z$. 

$$
b_0 = -\frac{\mu}{\sigma}
$$
It is possible for the roots of the equation for $r$ to be imaginary or for the confidence interval to be all points outside of an interval. In these cases, the limits are set to missing by the PROBIT procedure.

Although the normal and logistic distribution give comparable fitted values of $p$ if the empirically observed proportions are not too extreme, they can give appreciably different values when extrapolated into the tails. Correspondingly, the estimates of the confidence limits and dose values can be different for the two distributions even when they agree quite well in the body of the data. Extrapolation outside of the range of the actual data are often sensitive to model assumptions, and caution is advised if extrapolation is necessary.

OUTEST= SAS-data-set

The OUTEST= data set contains parameter estimates and the log likelihood for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different modeling using the PROBIT procedure. If you specify the COVOUT option, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates.

The OUTEST= data set contains each variable used as a dependent or independent variable in any MODEL statement. One observation consists of parameter values for the model with the dependent variable having the value $-1$. If you specify the COVOUT option, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

- **MODEL**  a character variable containing the label of the MODEL statement, if present, or blank otherwise
- **NAME**  a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates
- **TYPE**  a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates
- **DIST**  a character variable containing the name of the distribution modeled
- **LNLIKE**  a numeric variable containing the last computed value of the log likelihood
- **C**  a numeric variable containing the estimated threshold parameter

**INTERCEPT**  a numeric variable containing the intercept parameter estimates and covariances

Any BY variables specified are also added to the OUTEST= data set.
The XDATA= data set is used for specifying values for the effects in the MODEL statement when predicted values and/or fiducial limits for a single continuous variable (dose variable) are required. It is also used for plots specified by the CDFPLOT, IPPPLOT, LPREDPLOT, and PREDPLOT statement.

The XDATA= data names a SAS data set that contains user input values for all the independent variables in the MODEL statement and the variables in the CLASS statement. The XDATA= data set has the same structure as the DATA= data set but is not required to have all the variables or observations that appear in the DATA= data set.

The XDATA= data set must contain all the independent variables in the MODEL statement and variables in the CLASS statement. Even though variables in the CLASS statement may not be used in the MODEL statement, valid values are required for these variables in the XDATA= data set. Missing values are not allowed. For independent variables in the MODEL statement, although the dose variable’s value is not used in the computing of predicted values and/or fiducial limits for the dose variable, missing values are not allowed in the XDATA= data set for any of the independent variables. Missing values are allowed for the dependent variables and other variables if they are included in the XDATA= data set and not listed in the CLASS statement.

If BY processing is used, the XDATA= data set should also include the BY variables, and there must be at least one valid observation for each BY group. If there is more than one valid observation in one BY group, the last one read is used for that BY group.

If there is no XDATA= data set in the PROC PROBIT statement, by default, the PROBIT procedure will use overall mean for effects containing continuous variable (or variables) and the highest level of a single classification variable as reference level. The rules are summarized as follows:

- If the effect contains a continuous variable (or variables), the overall mean of this effect is used.
- If the effect is a single classification variable, the highest level of the variable is used.

**Displayed Output**

If you request the iteration history (ITPRINT), PROC PROBIT displays

- the current value of the log likelihood
- the ridging parameter for the modified Newton-Raphson optimization process
- the current estimate of the parameters
- the current estimate of the parameter $C$ for a natural (threshold) model
- the values of the gradient and the Hessian on the last iteration
If you include CLASS variables, PROC PROBIT displays

- the numbers of levels for each CLASS variable
- the (ordered) values of the levels
- the number of observations used

After the model is fit, PROC PROBIT displays

- the name of the input data set
- the name of the dependent variables
- the number of observations used
- the number of events and the number of trials
- the final value of the log-likelihood function
- the parameter estimates
- the standard error estimates of the parameter estimates
- approximate chi-square test statistics for the test

If you specify the COVB or CORRB options, PROC PROBIT displays

- the estimated covariance matrix for the parameter estimates
- the estimated correlation matrix for the parameter estimates

If you specify the LACKFIT option, PROC PROBIT displays

- a count of the number of levels of the response and the number of distinct sets of independent variables
- a goodness-of-fit test based on the Pearson chi-square
- a goodness-of-fit test based on the likelihood-ratio chi-square

If you specify only one independent variable, the normal distribution is used to model the probabilities, and the response is binary, PROC PROBIT displays

- the mean MU of the stimulus tolerance
- the scale parameter SIGMA of the stimulus tolerance
- the covariance matrix for MU, SIGMA, and the natural response parameter C

If you specify the INVERSECL options, PROC PROBIT also displays

- the estimated dose along with the 95% fiducial limits for probability levels 0.01 to 0.10, 0.15 to 0.85 by 0.05, and 0.90 to 0.99
PROC PROBIT assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”

* Depends on data.
Examples

Example 60.1. Dosage Levels

In this example, Dose is a variable representing the level of a stimulus, N represents the number of subjects tested at each level of the stimulus, and Response is the number of subjects responding to that level of the stimulus. Both probit and logit response models are fit to the data. The LOG10 option in the PROC PROBIT statement requests that the log base 10 of Dose is used as the independent variable. Specifically, for a given level of Dose, the probability $p$ of a positive response is modeled as

$$p = \Pr(\text{Response}) = F(b_0 + b_1 \times \log_{10}(\text{Dose}))$$

The probabilities are estimated first using the normal distribution function (the default) and then using the logistic distribution function. Note that, in this model specification, the natural rate is assumed to be zero.

The LACKFIT option specifies lack-of-fit tests and the INVERSECL option specifies inverse confidence limits.

In the DATA step that reads the data, a number of observations are generated that have a missing value for the response. Although the PROBIT procedure does not use the observations with the missing values to fit the model, it does give predicted values for all nonmissing sets of independent variables. These data points fill in the plot of fitted and observed values in the logistic model displayed in Output 60.1.2. The plot, requested with the PREDPPLLOT statement, displays the estimated logistic cumulative distribution function and the observed response rates. The VAR= DOSE option specifies the horizontal axis variable in the plot.

The following statements produce Output 60.1.1:

```plaintext

Both the ED50 and the LD50 are similar to those for the normal model.

The statement PREDPPLLOT creates the plot of observed and fitted probabilities in **Output 60.1.2**. The dashed line represent pointwise confidence bands for the probabilities.
Example 60.2. Multilevel Response

In this example, two preparations, a standard preparation and a test preparation, are each given at several dose levels to groups of insects. The symptoms are recorded for each insect within each group, and two multilevel probit models are fit. Because the natural sort order of the three levels is not the same as the response order, the ORDER=DATA option is specified in the PROC PROBIT statement to get the desired order.

The following statements produce Output 60.2.1:

```sas
DATA multi;
  INPUT Prep $ Dose Symptoms $ N;
  LDose=log10(Dose);
  IF Prep='test' THEN PrepDose=LDose;
  ELSE PrepDose=0;
  DATALINES;
stand 10 None 33
stand 10 Mild 7
stand 10 Severe 10
stand 20 None 17
stand 20 Mild 13
stand 20 Severe 17
stand 30 None 14
stand 30 Mild 3
stand 30 Severe 28
stand 40 None 9
stand 40 Mild 8
stand 40 Severe 32
```

Output 60.2.1. Plot of Observed and Fitted Probabilities

![Plot of Observed and Fitted Probabilities](image)

- X-axis: Dose
- Y-axis: Probability
- Points represent observed probabilities, and curves represent fitted probabilities.
test 10 None 44
test 10 Mild 6
test 10 Severe 0
test 20 None 32
test 20 Mild 10
test 20 Severe 12
test 30 None 23
test 30 Mild 7
test 30 Severe 21
test 40 None 16
test 40 Mild 6
test 40 Severe 19;

proc probit order=data;
class Prep Symptoms;
  nonpara: model Symptoms=Prep LDose PrepDose / lackfit;
  weight N;
  title 'Probit Models for Symptom Severity';
run;

proc probit order=data;
class Prep Symptoms;
  parallel: model Symptoms=Prep LDose / lackfit;
  weight N;
  title 'Probit Models for Symptom Severity';
run;

The first model allows for nonparallelism between the dose response curves for the two preparations by inclusion of an interaction between Prep and LDose. The interaction term is labeled PrepDose in the “Analysis of Parameter Estimates” table. The results of this first model indicate that the parameter for the interaction term is not significant, having a Wald chi-square of 0.73. Also, since the first model is a generalization of the second, a likelihood ratio test statistic for this same parameter can be obtained by multiplying the difference in log likelihoods between the two models by 2. The value obtained, $2 \times (-345.94 - (-346.31))$, is 0.73. This is in close agreement with the Wald chi-square from the first model. The lack-of-fit test statistics for the two models do not indicate a problem with either fit.

</table>
The negative coefficient associated with LDose indicates that the probability of having no symptoms (Symptoms='None') or no or mild symptoms (Symptoms='None' or Symptoms='Mild') decreases as LDose increases; that is, the probability of a severe symptom increases with LDose. This association is apparent for both treatment groups.

The negative coefficient associated with the standard treatment group (Prep = stand) indicates that the standard treatment is associated with more severe symptoms across all Ldose values.

The following statements use the PREDPLOT statement to create the plot shown in Output 60.2.2 of the probabilities of the response taking on individual levels as a function of LDose. Since there are two covariates, LDose and Prep, the value of the CLASS variable Prep is fixed at the highest level, test. Although not shown here, the CDFPLOT statement creates similar plots of the cumulative response probabilities, instead of individual response level probabilities.

```proc probit data=multi order=data;
   class Prep Symptoms;
   parallel: model Symptoms=Prep LDose / lackfit;
   predpplot var=ldose level=("None" "Mild" "Severe")
      cfit=blue cframe=ligr inborder noconf;
   weight N;
```
The following statements use the XDATA= data set to create a plot of the predicted probabilities with Prep set to the stand level. The resulting plot is shown in Output 60.2.3.

```sas
data xrow;
  input Prep $ Dose Symptoms $ N;
  LDose=log10(Dose);
  datalines;
  stand 40 Severe 32
run;

proc probit data=multi order=data xdata=xrow;
  class Prep Symptoms;
  parallel: model Symptoms=Prep LDose / lackfit;
  predpplot var=ldose level=("None" "Mild" "Severe")
    cfit=blue cframe=ligr inborder noconf ;
  weight N;
  title 'Predicted Probabilities for Standard Preparation';
run;
```
**Example 60.3. Logistic Regression**

In this example, a series of people are questioned as to whether or not they would subscribe to a new newspaper. For each person, the variables `sex` (Female, Male), `age`, and `subs` (1=yes, 0=no) are recorded. The PROBIT procedure is used to fit a logistic regression model to the probability of a positive response (subscribing) as a function of the variables `sex` and `age`. Specifically, the probability of subscribing is modeled as

\[ p = \Pr(\text{subs} = 1) = F(b_0 + b_1 \times \text{sex} + b_2 \times \text{age}) \]

where \( F \) is the cumulative logistic distribution function.

By default, the PROBIT procedure models the probability of the lower response level for binary data. One way to model \( \Pr(\text{subs} = 1) \) is to format the response variable so that the formatted value corresponding to `subs=1` is the lower level. The following statements format the values of `subs` as 1 = 'accept' and 0 = 'reject', so that PROBIT models \( \Pr(\text{accept}) = \Pr(\text{subs} = 1) \).

The following statements produce **Output 60.3.1**:

```plaintext
data news;
  input sex $ age subs;
datalines;
Female 35 0
Male 44 0
Male 45 1
```

From Output 60.3.1, there appears to be an effect due to both the variables SEX and age. The positive coefficient for age indicates that older people are more likely to subscribe than younger people. The negative coefficient for SEX indicates that females are less likely to subscribe than males.
Example 60.4. An Epidemiology Study

The data, which is from an epidemiology study, consists of five variables: the number, \( r \), of individuals surviving after an epidemic, out of \( n \) treated, for combinations of medicine dosage (\texttt{dose}), treatment (\texttt{treat} = A, B), and sex (\texttt{sex} = 0(Female), 1(Male)).

To see if the two treatments have different effects on male and female individual survival rate, the interaction term between the two variables \texttt{treat} and \texttt{sex} is included in the model.

The following invocation of PROC PROBIT fits the binary probit model to the grouped data:

```sas
data epidemic;
  input treat$ dose n r sex;
  label dose = Dose;
  datalines;
  A  2.17 142 142 0
  A  .57 132 47 1
  A  1.68 128 105 1
  A  1.08 126 100 0
  A  1.79 125 118 0
  B  1.66 117 115 1
  B  1.49 127 114 0
  B  1.17 51 44 1
  B  2.00 127 126 0
  B  .80 129 100 1
;

data xval;
  input treat $ dose sex ;
  datalines;
  B  2. 1
;

title 'Epidemiology Study';
proc probit optc lackfit covout data = epidemic
  outest = out1 xdata = xval;
  class treat sex;
  model r/n = dose treat sex sex*treat/corrb covb inversecl;
  output out = out2 p =p;
  predpplot
    var = dose
    font = swiss
    vref(intersect) = .6667
    vreflab = 'two thirds'
    vreflabpos = 2
    cfit=blue
    cframe=ligr
    ;
inset /
```
The results of this analysis are shown in the following tables and figures.

Beginning with SAS Release 8.2, the PROBIT procedure does not support multiple MODEL statements. Only the last one is used if there is more than one MODEL statement in one invocation of the PROBIT procedure.

Output 60.4.1. Class Level Information

```
Epidemiology Study

Probit Procedure

Class Level Information

Output 60.4.2 displays the table of parameter information for the effects in the MODEL statement. The name of a parameter is generated from combining the variable names and level names in the effect. The maximum length of a parameter name is 32. The name of the effects are specified in the MODEL statement. The length of names of effects can be specified by the NAMELEN= option in the PROC PROBIT statement, with the default length 20.

Output 60.4.3. Model Information

</tbody>
</table>

Response-Covariate Profile

- Response Levels: 2
- Number of Covariate Values: 10

Output 60.4.4 displays the table of goodness-of-fit tests requested with the LACKFIT option in the PROC PROBIT statement. Two goodness-of-fit statistics, the Pearson chi-square statistic and the likelihood ratio chi-square statistic, are computed. The grouping method for computing these statistics can be specified by the AGGREGATE= option. The details can be found in the AGGREGATE= option and an example can be found in the second part of this example. By default, the PROBIT procedure uses the covariates in the MODEL statement to do grouping. Observations with the same values of the covariates in the MODEL statement are grouped into cells and the two statistics are computed according to these cells. The total number of cells, and the number of levels for the response variable are reported next in the “Response-Covariate Profile.”

In this example, neither the Pearson chi-square nor the log-likelihood ratio chi-square tests are significant at the 0.1 level, which is the default test level used by the PROBIT procedure. That means that the model, which includes the interaction of treat and sex, is suitable for this epidemiology data set. (Further investigation shows that models without the interaction of treat and sex are not acceptable by either test.)

Output 60.4.5. Type III Tests

Epidemiology Study

Probit Procedure

Type III Analysis of Effects

</tbody>
</table>

Output 60.4.6 displays the table of parameter estimates for the model. The PROBIT procedure displays information for all the parameters of an effect. Degenerate parameters are indicated by 0 degree of freedom. Confidence intervals are computed for all parameters with non-zero degrees of freedom, including the natural threshold C if the OPTC option is specified in the PROC PROBIT statement. The confidence level can be specified by the ALPHA= option in the MODEL statement. The default confidence level is 95%.

From this table, you can see the following results:

- **dose** has significant positive effect on the survival rate.
- Individuals under treatment A have a lower survival rate.
- Male individuals have a higher survival rate.
- Female individuals under treatment A have a higher survival rate.

</tbody>
</table>

Output 60.4.7 and Output 60.4.8 display tables of estimated covariance matrix and estimated correlation matrix for estimated parameters with a non-zero degree of freedom, respectively. They are computed by the inverse of the Hessian matrix of the estimated parameters.
Output 60.4.9 displays the computed values and fiducial limits for the first single continuous variable dose in the MODEL statement, given the probability levels, without the effect of the natural threshold, and when the option INVERSECL in the MODEL statement is specified. If there is no single continuous variable in the MODEL specification but the INVERSECL option is specified, an error is reported. If the XDATA= option is used to input a data set for the independent variables in the MODEL statement, the PROBIT procedure uses these values for the independent variables other than the single continuous variable. Missing values are not permitted in the XDATA= data set for the independent variables, although the value for the single continuous variable is not used in the computing of the fiducial limits. A suitable valid value should be given. In the data set xval created by the SAS statements on page 3784, Dose = 2.
See the section “XDATA= SAS-data-set” on page 3763 for the default values for those effects other than the single continuous variable, for which the fiducial limits are computed.

In this example, there are two classification variables, treat and sex. Fiducial limits for the dose variable are computed for the highest level of the classification variables, treat = B and sex = 1, which is the default specification. Since these are the default values, you would get the same values and fiducial limits if you did not specify the XDATA= option in this example. The confidence level for the fiducial limits can be specified by the ALPHA= option in the MODEL statement. The default level is 95%.

If a LOG10 or LOG option is used in the PROC PROBIT statement, the values and the fiducial limits are computed for both the single continuous variable and its logarithm.

Output 60.4.10 displays the OUTEST= data set. All parameters for an effect are included.

The following three outputs, **Output 60.4.11**, **Output 60.4.12**, and **Output 60.4.13**, are generated from the three plot statements. The first plot, specified with the PREDPPLLOT statement, is the plot of the predicted probability against the single continuous variable Dose, which is specified by the VAR= option in the PREDPPLLOT statement. This single continuous variable must be in the MODEL statement. If the VAR= option is not used, the first single continuous variable in the MODEL statement is used. In this example, you would get the same plot if the VAR = dose was not used in the PREDPPLLOT statement. You can specify values of other independent
variables in the MODEL statement using an XDATA= data set, or by using the default values.

The second plot, specified with the IPPPLOT statement, is the inverse of the predicted probability plot with the fiducial limits. It should be pointed out that the fiducial limits are not just the inverse of the confidence limits in the predicted probability plot; see the section “Inverse Confidence Limits” on page 3761 for the computation of these limits. The third plot, specified with the LPREDPLOT statement, is the plot of the linear predictor \( x' \beta \) against the first single continuous variable (or the single continuous variable specified by the VAR= option) with the Wald confidence intervals.

After each plot statement, an optional INSET statement is used to draw a box within the plot (inset box). In the inset box, information about the model fitting can be specified. See “INSET Statement” on page 3723 for more detail.

**Output 60.4.11.** Predicted Probability Plot

![Predicted Probability Plot](image)
Combining INEST= data set and the MAXIT= option in the MODEL statement, the PROBIT procedure can do prediction, if the parameterizations for the models used for the training data and the validation data are exactly the same.

After the first invocation of PROC PROBIT, you have the estimated parameters and their covariance matrix in the data set OUTEST = Out1, and the fitted probabilities for the training data set epidemic in the data set OUTPUT = Out2. See Output 60.4.10 on page 3791 for the data set Out1 and Output 60.4.14 on page 3795 for the data set Out2.
The validation data are collected in data set `validate`. The second invocation of PROC PROBIT simply passes the estimated parameters from the training data set `epidemic` to the validation data set `validate` for prediction. The predicted probabilities are stored in the data set `OUTPUT = Out3` (see Output 60.4.15 on page 3795). The third invocation of PROC PROBIT passes the estimated parameters as initial values for a new fit of the validation data set using the same model. Predicted probabilities are stored in the data set `OUTPUT = Out4` (see Output 60.4.16 on page 3795). Goodness-of-Fit tests are computed based on the cells grouped by the `AGGREGATE=` group variable. Results are shown in Output 60.4.17 on page 3796.

The REG procedure is one of many regression procedures in the SAS System. It is a general-purpose procedure for regression, while other SAS regression procedures provide more specialized applications. Other SAS/STAT procedures that perform at least one type of regression analysis are the CATMOD, GENMOD, GLM, LOGISTIC, MIXED, NLIN, ORTHOREG, PROBIT, RSREG, and TRANSREG procedures. SAS/ETS procedures are specialized for applications in time-series or simultaneous systems. These other SAS/STAT regression procedures are summarized in Chapter 2, “Introduction to Regression Procedures,” which also contains an overview of regression techniques and defines many of the statistics computed by PROC REG and other regression procedures.

PROC REG provides the following capabilities:

- multiple MODEL statements
- nine model-selection methods
- interactive changes both in the model and the data used to fit the model
- linear equality restrictions on parameters
- tests of linear hypotheses and multivariate hypotheses
- collinearity diagnostics
- predicted values, residuals, studentized residuals, confidence limits, and influence statistics
- correlation or crossproduct input
- requested statistics available for output through output data sets
- experimental ODS graphics are now available. For more information, see the “ODS Graphics” section on page 3922. These plots are available in addition to the line-printer and the traditional high resolution plots currently available in PROC REG.
- plots
  - plot model fit summary statistics and diagnostic statistics
  - produce normal quantile-quantile (Q-Q) and probability-probability (P-P) plots for statistics such as residuals
  - specify special shorthand options to plot ridge traces, confidence intervals, and prediction intervals
  - display the fitted model equation, summary statistics, and reference lines on the plot
— control the graphics appearance with PLOT statement options and with global graphics statements including the TITLE, FOOTNOTE, NOTE, SYMBOL, and LEGEND statements
— “paint” or highlight line-printer scatter plots
— produce partial regression leverage line-printer plots

Nine model-selection methods are available in PROC REG. In the simplest method, PROC REG fits the complete model that you specify. The other eight methods involve various ways of including or excluding variables from the model. You specify these methods with the SELECTION= option in the MODEL statement.

The methods are identified in the following list and are explained in detail in the “Model-Selection Methods” section on page 3873.

NONE no model selection. This is the default. The complete model specified in the MODEL statement is fit to the data.
FORWARD forward selection. This method starts with no variables in the model and adds variables.
BACKWARD backward elimination. This method starts with all variables in the model and deletes variables.
STEPWISE stepwise regression. This is similar to the FORWARD method except that variables already in the model do not necessarily stay there.
MAXR forward selection to fit the best one-variable model, the best two-variable model, and so on. Variables are switched so that $R^2$ is maximized.
MINR similar to the MAXR method, except that variables are switched so that the increase in $R^2$ from adding a variable to the model is minimized.
RSQUARE finds a specified number of models with the highest $R^2$ in a range of model sizes.
ADJRSQ finds a specified number of models with the highest adjusted $R^2$ in a range of model sizes.
CP finds a specified number of models with the lowest $C_p$ in a range of model sizes.

---

**Getting Started**

**Simple Linear Regression**

Suppose that a response variable $Y$ can be predicted by a linear function of a regressor variable $X$. You can estimate $\beta_0$, the intercept, and $\beta_1$, the slope, in

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$
for the observations \( i = 1, 2, \ldots, n \). Fitting this model with the REG procedure requires only the following MODEL statement, where \( y \) is the outcome variable and \( x \) is the regressor variable.

```plaintext
proc reg;
  model y=x;
run;
```

For example, you might use regression analysis to find out how well you can predict a child’s weight if you know that child’s height. The following data are from a study of nineteen children. Height and weight are measured for each child.

```plaintext
title 'Simple Linear Regression';
data Class;
  input Name $ Height Weight Age @@;
datalines;
  Alfred 69.0 112.5 14  Alice 56.5 84.0 13  Barbara 65.3 98.0 13  Carol 62.8 102.5 14  Henry 63.5 102.5 14  James 57.3 83.0 12  Jane 59.8 84.5 12  Janet 62.5 112.5 15  Jeffrey 62.5 84.0 13  John 59.0 99.5 12  Joyce 51.3 50.5 11  Judy 64.3 90.0 14  Louise 56.3 77.0 12  Mary 66.5 112.0 15  Philip 72.0 150.0 16  Robert 64.8 128.0 12  Ronald 67.0 133.0 15  Thomas 57.5 85.0 11  William 66.5 112.0 15
;
```

The equation of interest is

\[
\text{Weight} = \beta_0 + \beta_1 \text{Height} + \epsilon
\]

The variable \( \text{Weight} \) is the response or dependent variable in this equation, and \( \beta_0 \) and \( \beta_1 \) are the unknown parameters to be estimated. The variable \( \text{Height} \) is the regressor or independent variable, and \( \epsilon \) is the unknown error. The following commands invoke the REG procedure and fit this model to the data.

```plaintext
proc reg;
  model Weight = Height;
run;
```

Figure 61.1 includes some information concerning model fit.

R-Square 0.7705
Adj R-Square 0.7570

**Figure 61.1. ANOVA Table**

The $F$ statistic for the overall model is highly significant ($F$=57.076, $p<0.0001$), indicating that the model explains a significant portion of the variation in the data.

The degrees of freedom can be used in checking accuracy of the data and model. The model degrees of freedom are one less than the number of parameters to be estimated. This model estimates two parameters, $\beta_0$ and $\beta_1$; thus, the degrees of freedom should be $2 - 1 = 1$. The corrected total degrees of freedom are always one less than the total number of observations in the data set, in this case $19 - 1 = 18$.

Several simple statistics follow the ANOVA table. The Root MSE is an estimate of the standard deviation of the error term. The coefficient of variation, or Coeff Var, is a unitless expression of the variation in the data. The R-Square and Adj R-Square are two statistics used in assessing the fit of the model; values close to 1 indicate a better fit. The R-Square of 0.77 indicates that Height accounts for 77% of the variation in Weight.

The “Parameter Estimates” table shown in Figure 61.2 contains the estimates of $\beta_0$ and $\beta_1$. The table also contains the $t$ statistics and the corresponding $p$-values for testing whether each parameter is significantly different from zero. The $p$-values ($t = -4.43, p = 0.0004$ and $t = 7.55, p < 0.0001$) indicate that the intercept and Height parameter estimates, respectively, are highly significant.
Simple Linear Regression

The REG Procedure
Model: MODEL1
Dependent Variable: Weight

Parameter Estimates

| Variable | DF | Parameter Estimate | Standard Error | t Value | Pr > |t| |
|----------|----|--------------------|----------------|---------|-------|---|
| Intercept | 1  | -143.02692         | 32.27459       | -4.43   | 0.0004|
| Height   | 1  | 3.89903            | 0.51609        | 7.55    | <.0001|

Figure 61.2. Parameter Estimates

From the parameter estimates, the fitted model is

\[
\text{Weight} = -143.0 + 3.9 \times \text{Height}
\]

The REG procedure can be used interactively. After you specify a model with the MODEL statement and submit the PROC REG statements, you can submit further statements without reinvoking the procedure. The following command can now be issued to request a plot of the residual versus the predicted values, as shown in Figure 61.3.

```
plot r.*p.; run;
```

Figure 61.3. Plot of Residual vs. Predicted Values
A trend in the residuals would indicate nonconstant variance in the data. Figure 61.3 may indicate a slight trend in the residuals; they appear to increase slightly as the predicted values increase. A fan-shaped trend may indicate the need for a variance-stabilizing transformation. A curved trend (such as a semi-circle) may indicate the need for a quadratic term in the model. Since these residuals have no apparent trend, the analysis is considered to be acceptable.

**Polynomial Regression**

Consider a response variable $Y$ that can be predicted by a polynomial function of a regressor variable $X$. You can estimate $\beta_0$, the intercept, $\beta_1$, the slope due to $X$, and $\beta_2$, the slope due to $X^2$, in

$$Y_i = \beta_0 + \beta_1 X_i + \beta_2 X_i^2 + \epsilon_i$$

for the observations $i = 1, 2, \ldots, n$.

Consider the following example on population growth trends. The population of the United States from 1790 to 2000 is fit to linear and quadratic functions of time. Note that the quadratic term, YearSq, is created in the DATA step; this is done since polynomial effects such as Year*Year cannot be specified in the MODEL statement in PROC REG. The data are as follows:

```r
data USPopulation;
  input Population @@;
  retain Year 1780;
  Year=Year+10;
  YearSq=Year*Year;
  Population=Population/1000;
  datalines;
  3929 5308 7239 9638 12866 17069 23191 31443 39818 50155
  62947 75994 91972 105710 122775 131669 151325 179323 203211
  226542 248710 281422;
```

The following statements begin the analysis. (Influence diagnostics and autocorrelation information for the full model are shown in Figure 61.43 on page 3900 and Figure 61.57 on page 3916.)

```r
symbol1 c=blue;
proc reg data=USPopulation;
  var YearSq;
  model Population=Year / r cli clm;
  plot r.*p. / cframe=ligr;
run;
```

The DATA option ensures that the procedure uses the intended data set. Any variable that you might add to the model but that is not included in the first MODEL statement must appear in the VAR statement. In the MODEL statement, three options are
specified: R requests a residual analysis to be performed, CLI requests 95% confidence limits for an individual value, and CLM requests these limits for the expected value of the dependent variable. You can request specific $100(1 - \alpha)$% limits with the ALPHA= option in the PROC REG or MODEL statement. A plot of the residuals against the predicted values is requested by the PLOT statement.

The ANOVA table is displayed in Figure 61.4.

Figure 61.4. ANOVA Table and Parameter Estimates

The Model $F$ statistic is significant ($F=228.92, p<0.0001$), indicating that the model accounts for a significant portion of variation in the data. The R-Square indicates that the model accounts for 92% of the variation in population growth. The fitted equation for this model is

\[
\text{Population} = -2345.85 + 1.29 \times \text{Year}
\]

Figure 61.5 shows the confidence limits for both individual and expected values resulting from the CLM and CLI options.

**Figure 61.5.** Confidence Limits

The observed dependent variable is displayed for each observation along with its predicted value from the regression equation and the standard error of the mean predicted value. The 95% CL Mean columns are the confidence limits for the expected value of each observation. The 95% CL Predict columns are the confidence limits for the individual observations.

**Figure 61.6** displays the residual analysis requested by the R option.

---

**Figure 61.6.** Residual Analysis

The residual, its standard error, and the studentized residuals are displayed for each observation. The studentized residual is the residual divided by its standard error. The magnitude of each studentized residual is shown in a plot. Studentized residuals follow a $t$ distribution and can be used to identify outlying or extreme observations. Asterisks (*) extending beyond the dashed lines indicate that the residual is more than three standard errors from zero. Many observations having absolute studentized residuals greater than 2 may indicate an inadequate model. The wave pattern seen in this plot is also an indication that the model is inadequate; a quadratic term may be needed or autocorrelation may be present in the data. Cook’s D is a measure of the change in the predicted values upon deletion of that observation from the data set; hence, it measures the influence of the observation on the estimated regression coefficients. A fairly close agreement between the PRESS statistic (see Table 61.6 on page 3897) and the Sum of Squared Residuals indicates that the MSE is a reasonable measure of the predictive accuracy of the fitted model (Neter, Wasserman, and Kutner, 1990).

A plot of the residuals versus predicted values is shown in Figure 61.7.
Figure 61.7. Plot of Residual vs. Predicted Values

The wave pattern of the studentized residual plot is seen here again. The semi-circle shape indicates an inadequate model; perhaps additional terms (such as the quadratic) are needed, or perhaps the data need to be transformed before analysis. If a model fits well, the plot of residuals against predicted values should exhibit no apparent trends.

Using the interactive feature of PROC REG, the following commands add the variable YearSq to the independent variables and refit the model.

```
add YearSq;
print;
plot / cframe=ligr;
run;
```

The ADD statement requests that YearSq be added to the model, and the PRINT command displays the ANOVA table for the new model. The PLOT statement with no variables recreates the most recent plot requested, in this case a plot of residual versus predicted values.

Figure 61.8 displays the ANOVA table and estimates for the new model.

| YearSq   | 1  | 0.00668             | 0.00017820     | 37.51   | <.0001 |

**Figure 61.8.** ANOVA Table and Parameter Estimates

The overall $F$ statistic is still significant ($F=8864.19$, $p<0.0001$). The R-square has increased from 0.9197 to 0.9989, indicating that the model now accounts for 99.9% of the variation in Population. All effects are significant with $p<0.0001$ for each effect in the model.

The fitted equation is now

$$\text{Population} = 21631 - 24.046 \times \text{Year} + 0.0067 \times \text{YearSq}$$

The confidence limits and residual analysis for the second model are displayed in **Figure 61.9**.

#### Summary Statistics

- **Sum of Residuals:** -4.4596E-11
- **Sum of Squared Residuals:** 170.97193
- **Predicted Residual SS (PRESS):** 237.71229
**Figure 61.9.** Confidence Limits and Residual Analysis

The plot of the studentized residuals shows that the wave structure is gone. The PRESS statistic is much closer to the Sum of Squared Residuals now, and both statistics have been dramatically reduced. Most of the Cook’s D statistics have also been reduced.

![Plot of the studentized residuals](image)

**Figure 61.10.** Plot of Residual vs. Predicted Values

The plot of residuals versus predicted values seen in Figure 61.10 has improved since a major trend is no longer visible.

To create a plot of the observed values, predicted values, and confidence limits against Year all on the same plot and to exert some control over the look of the resulting plot, you can submit the following statements.

```sas
symbol1 v=dot c=yellow h=.3;
symbol2 v=square c=red;
symbol3 f=simplex c=blue h=2 v='-';
symbol4 f=simplex c=blue h=2 v='-';
plot (Population predicted. u95. l95.)*Year
/ overlay cframe=ligr;
run;
```
The SYMBOL statements requests that the actual data be displayed as dots, the predicted values as squares, and the upper and lower 95% confidence limits for an individual value (sometimes called a prediction interval) as dashes. PROC REG provides the short-hand commands CONF and PRED to request confidence and prediction intervals for simple regression models; see the “PLOT Statement” section on page 3839 for details.

To complete an analysis of these data, you may want to examine influence statistics and, since the data are essentially time series data, examine the Durbin-Watson statistic. You might also want to examine other residual plots, such as the residuals vs. regressors.

**Using PROC REG Interactively**

PROC REG can be used interactively. After you specify a model with a MODEL statement and run REG with a RUN statement, a variety of statements can be executed without reinvoking REG.

The “Interactive Analysis” section on page 3869 describes which statements can be used interactively. These interactive statements can be executed singly or in groups by following the single statement or group of statements with a RUN statement. Note that the MODEL statement can be repeated. This is an important difference from the GLM procedure, which allows only one MODEL statement.

If you use REG interactively, you can end the REG procedure with a DATA step, another PROC step, an ENDSAS statement, or with a QUIT statement. The syntax
of the QUIT statement is

    quit;

When you are using REG interactively, additional RUN statements do not end REG but tell the procedure to execute additional statements.

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure.

When using REG interactively, you can fit a model, perform diagnostics, then refit the model, and perform diagnostics on the refitted model. Most of the interactive statements implicitly refit the model; for example, if you use the ADD statement to add a variable to the model, the regression equation is automatically recomputed. The two exceptions to this automatic recomputing are the PAINT and REWEIGHT statements. These two statements do not cause the model to be refitted. To do so, you can follow these statements either with a REFIT statement, which causes the model to be explicitly recomputed, or with another interactive statement that causes the model to be implicitly recomputed.

## Syntax

The following statements are available in PROC REG.

```plaintext
PROC REG < options > ;
    < label: > MODEL dependents=<regressors> < / options > ;
    BY variables ;
    FREQ variable ;
    ID variables ;
    VAR variables ;
    WEIGHT variable ;
    ADD variables ;
    DELETE variables ;
    < label: > MTEST <equation, . . . ,equation> < / options > ;
OUTPUT < OUT=SAS-data-set > keyword=names < . . . keyword=names > ;
    PAINT <condition | ALLOBS>
        < / options > | < STATUS | UNDO> ;
    PLOT <yvariable>xvariable <symbol>
        < . . . yvariable>xvariable <symbol> < / options > ;
    PRINT <options > < ANOVA > < MODELDATA > ;
    REFIT ;
    RESTRICT equation, . . . ,equation ;
    REWEIGHT <condition | ALLOBS>
        < / options > | < STATUS | UNDO> ;
    < label: > TEST equation, < . . . ,equation> < / option > ;
```
Although there are numerous statements and options available in PROC REG, many analyses use only a few of them. Often you can find the features you need by looking at an example or by scanning this section.

In the preceding list, brackets denote optional specifications, and vertical bars denote a choice of one of the specifications separated by the vertical bars. In all cases, \textit{label} is optional.

The PROC REG statement is required. To fit a model to the data, you must specify the MODEL statement. If you want to use only the options available in the PROC REG statement, you do not need a MODEL statement, but you must use a VAR statement. (See the example in the “OUTSSCP= Data Sets” section on page 3868.) Several MODEL statements can be used. In addition, several MTEST, OUTPUT, PAINT, PLOT, PRINT, RESTRICT, and TEST statements can follow each MODEL statement. The ADD, DELETE, and REWEIGHT statements are used interactively to change the regression model and the data used in fitting the model. The ADD, DELETE, MTEST, OUTPUT, PLOT, PRINT, RESTRICT, and TEST statements implicitly refit the model; changes made to the model are reflected in the results from these statements. The REFIT statement is used to refit the model explicitly and is most helpful when it follows PAINT and REWEIGHT statements, which do not refit the model. The BY, FREQ, ID, VAR, and WEIGHT statements are optionally specified once for the entire PROC step, and they must appear before the first RUN statement.

When TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets are used as input data sets to PROC REG, statements and options that require the original data are not available. Specifically, the OUTPUT, PAINT, PLOT, and REWEIGHT statements and the MODEL and PRINT statement options P, R, CLM, CLI, DW, DWPROB, INFLUENCE, and PARTIAL are disabled.

You can specify the following statements with the REG procedure in addition to the PROC REG statement:

- **ADD** adds independent variables to the regression model.
- **BY** specifies variables to define subgroups for the analysis.
- **DELETE** deletes independent variables from the regression model.
- **FREQ** specifies a frequency variable.
- **ID** names a variable to identify observations in the tables.
- **MODEL** specifies the dependent and independent variables in the regression model, requests a model selection method, displays predicted values, and provides details on the estimates (according to which options are selected).
- **MTEST** performs multivariate tests across multiple dependent variables.
- **OUTPUT** creates an output data set and names the variables to contain predicted values, residuals, and other diagnostic statistics.
- **PAINT** paints points in scatter plots.
- **PLOT** generates scatter plots.
PRINT displays information about the model and can reset options.
REFIT refits the model.
RESTRICT places linear equality restrictions on the parameter estimates.
REWEIGHT excludes specific observations from analysis or changes the weights of observations used.
TEST performs an $F$ test on linear functions of the parameters.
VAR lists variables for which crossproducts are to be computed, variables that can be interactively added to the model, or variables to be used in scatter plots.
WEIGHT declares a variable to weight observations.

**PROC REG Statement**

```
PROC REG < options > ;
```

The PROC REG statement is required. If you want to fit a model to the data, you must also use a MODEL statement. If you want to use only the PROC REG options, you do not need a MODEL statement, but you must use a VAR statement. If you do not use a MODEL statement, then the COVOUT and OUTEST= options are not available.

Table 61.1 lists the options you can use with the PROC REG statement. Note that any option specified in the PROC REG statement applies to all MODEL statements.

</table>

Following are explanations of the options that you can specify in the PROC REG statement (in alphabetical order). Note that any option specified in the PROC REG statement applies to all MODEL statements.

**ALL**
requests the display of many tables. Using the ALL option in the PROC REG statement is equivalent to specifying ALL in every MODEL statement. The ALL option also implies the CORR, SIMPLE, and USCCP options.

**ALPHA=number**
sets the significance level used for the construction of confidence intervals. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the PROC REG option TABLEOUT; the MODEL options CLB, CLI, and CLM; the OUTPUT statement keywords LCL, LCLM, UCL, and UCLM; the PLOT statement keywords LCL, LCLM, UCL, and UCLM; and the PLOT statement options CONF and PRED.

**ANNOTATE=SAS-data-set**
**ANNO= SAS-data-set**
specifies an input data set containing annotate variables, as described in *SAS/GRAFH Software: Reference*. You can use this data set to add features to plots. Features provided in this data set are applied to all plots produced in the current run of PROC REG. To add features to individual plots, use the ANNOTATE= option in the PLOT statement. This option cannot be used if the LINEPRINTER option is specified.
**PROC REG Statement**

**CORR**
-displays the correlation matrix for all variables listed in the MODEL or VAR statement.

**COVOUT**
-outputs the covariance matrices for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is also specified. See the "OUTEST= Data Set" section on page 3863.

**DATA=SAS-data-set**
-names the SAS data set to be used by PROC REG. The data set can be an ordinary SAS data set or a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set. If one of these special TYPE= data sets is used, the OUTPUT, PAINT, PLOT, and REWEIGHT statements and some options in the MODEL and PRINT statements are not available. See Appendix A, “Special SAS Data Sets,” for more information on TYPE= data sets. If the DATA= option is not specified, PROC REG uses the most recently created SAS data set.

**EDF**
-outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model $R^2$ to the OUTEST= data set.

**GOUT=graphics-catalog**
specifies the graphics catalog in which graphics output is saved. The default graphics-catalog is WORK.GSEG. The GOUT= option cannot be used if the LINEPRINTER option is specified.

**LINEPRINTER | LP**
creates plots requested as line printer plots. If you do not specify this option, requested plots are created on a high resolution graphics device. This option is required if plots are requested and you do not have SAS/GRAPH software.

**NOPRINT**
suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

**OUTEST=SAS-data-set**
-requests that parameter estimates and optional model fit summary statistics be output to this data set. See the “OUTEST= Data Set” section on page 3863 for details. If you want to create a permanent SAS data set, you must specify a two-level name (refer to the section “SAS Files” in SAS Language Reference: Concepts for more information on permanent SAS data sets).

**OUTSEB**
-outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable _TYPE_ identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable _TYPE_. The standard errors for ridge regression estimates and IPC estimates are limited in their
usefulness because these estimates are biased. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

**OUTSSCP=SAS-data-set**
requests that the sums of squares and crossproducts matrix be output to this TYPE=SSCP data set. See the “OUTSSCP= Data Sets” section on page 3868 for details. If you want to create a permanent SAS data set, you must specify a two-level name (refer to the section “SAS Files” in SAS Language Reference: Concepts for more information on permanent SAS data sets).

**OUTSTB**
outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable _TYPE_ identify ridge regression estimates and IPC estimates, respectively.

**OUTVIF**
outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable _TYPE_.

**PCOMIT=list**
requests an incomplete principal components (IPC) analysis for each value m in the list. The procedure computes parameter estimates using all but the last m principal components. Each value of m produces a set of IPC estimates, which are output to the OUTEST= data set. The values of m are saved by the variable _PCOMIT_, and the value of the variable _TYPE_ is set to IPC to identify the estimates. Only nonnegative integers can be specified with the PCOMIT= option.

If you specify the PCOMIT= option, RESTRICT statements are ignored.

**PRESS**
outputs the PRESS statistic to the OUTEST= data set. The values of this statistic are saved in the variable _PRESS_. This option is available for all model selection methods except RSQUARE, ADJRSQ, and CP.

**RIDGE=list**
requests a ridge regression analysis and specifies the values of the ridge constant k (see the “Computations for Ridge Regression and IPC Analysis” section on page 3916). Each value of k produces a set of ridge regression estimates that are placed in the OUTEST= data set. The values of k are saved by the variable _RIDGE_, and the value of the variable _TYPE_ is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. Example 61.10 on page 3956 illustrates this option.

If ODS graphics are in effect (see the “ODS Graphics” section on page 3922), then ridge regression plots are automatically produced. These plots consist of panels containing ridge traces for the regressors, with at most eight ridge traces per panel.
BY Statement

If you specify the RIDGE= option, RESTRICT statements are ignored.

**RSQUARE**

has the same effect as the EDF option.

**SIMPLE**

displays the sum, mean, variance, standard deviation, and uncorrected sum of squares for each variable used in PROC REG.

**SINGULAR=n**

tunes the mechanism used to check for singularities. The default value is machine dependent but is approximately $1E^{-7}$ on most machines. This option is rarely needed. Singularity checking is described in the “Computational Methods” section on page 3917.

**TABLEOUT**

outputs the standard errors and $100(1 - \alpha)\%$ confidence limits for the parameter estimates, the $t$ statistics for testing if the estimates are zero, and the associated $p$-values to the OUTEST= data set. The _TYPE_ variable values STDERR, LnB, UnB, T, and PVALUE, where $n = 100(1 - \alpha)$, identify these rows in the OUTEST= data set. The $\alpha$-level can be set with the ALPHA= option in the PROC REG or MODEL statement. The OUTEST= option must be specified in the PROC REG statement for this option to take effect.

**USSCP**

displays the uncorrected sums-of-squares and crossproducts matrix for all variables used in the procedure.

---

**ADD Statement**

```
ADD variables;
```

The ADD statement adds independent variables to the regression model. Only variables used in the VAR statement or used in MODEL statements before the first RUN statement can be added to the model. You can use the ADD statement interactively to add variables to the model or to include a variable that was previously deleted with a DELETE statement. Each use of the ADD statement modifies the MODEL label. See the “Interactive Analysis” section on page 3869 for an example.

---

**BY Statement**

```
BY variables;
```

You can specify a BY statement with PROC REG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in the order of the BY variables. The variables are one or more variables in the input data set.

If your input data set is not sorted in ascending order, use one of the following alternatives.
• Sort the data using the SORT procedure with a similar BY statement.
• Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the REG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
• Create an index on the BY variables using the DATASETS procedure (in base SAS software).

When a BY statement is used with PROC REG, interactive processing is not possible; that is, once the first RUN statement is encountered, processing proceeds for each BY group in the data set, and no further statements are accepted by the procedure. A BY statement that appears after the first RUN statement is ignored.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Contents. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

DELETE Statement

DELETE variables;

The DELETE statement performs the opposite function of the ADD statement and is used in a similar manner. Each use of the DELETE statement modifies the MODEL label. For an example of how the ADD statement is used (and how the DELETE statement can be used), see the “Interactive Analysis” section on page 3869.

FREQ Statement

FREQ variable;

When a FREQ statement appears, each observation in the input data set is assumed to represent \( n \) observations, where \( n \) is the value of the FREQ variable. The analysis produced using a FREQ statement is the same as an analysis produced using a data set that contains \( n \) observations in place of each observation in the input data set. When the procedure determines degrees of freedom for significance tests, the total number of observations is considered to be equal to the sum of the values of the FREQ variable.

If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

The FREQ statement must appear before the first RUN statement, or it is ignored.
**ID Statement**

ID variables ;

When one of the MODEL statement options CLI, CLM, P, R, or INFLUENCE is requested, the variables listed in the ID statement are displayed beside each observation. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

Although there are no restrictions on the length of ID variables, PROC REG may truncate ID values to 16 characters for display purposes.

**MODEL Statement**

< label: > MODEL dependents=<regressors> < / options > ;

After the keyword MODEL, the dependent (response) variables are specified, followed by an equal sign and the regressor variables. Variables specified in the MODEL statement must be numeric variables in the data set being analyzed. For example, if you want to specify a quadratic term for variable X1 in the model, you cannot use X1*X1 in the MODEL statement but must create a new variable (for example, X1SQUARE=X1*X1) in a DATA step and use this new variable in the MODEL statement. The label in the MODEL statement is optional.

Table 61.2 lists the options available in the MODEL statement. Equations for the statistics available are given in the “Model Fit and Diagnostic Statistics” section on page 3896.

<tr>
<td>SINGULAR=</td>
<td>sets criterion for checking for singularity</td>
</tr>
</tbody>
</table>

You can specify the following options in the MODEL statement after a slash (/).

**ACOV**

displays the estimated asymptotic covariance matrix of the estimates under the hypothesis of heteroscedasticity. See the section “Testing for Heteroscedasticity” on page 3910 for more information.
ADJRSQ
computes $R^2$ adjusted for degrees of freedom for each model selected (Darlington 1968; Judge et al. 1980).

AIC
outputs Akaike’s information criterion for each model selected (Akaike 1969; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the AIC statistic is also added to the SubsetSelSummary table.

ALL
requests all these options: ACOV, CLB, CLI, CLM, CORRB, COVB, I, P, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, and XPX.

ALPHA=number
sets the significance level used for the construction of confidence intervals for the current MODEL statement. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals. This option affects the MODEL options CLB, CLI, and CLM; the OUTPUT statement keywords LCL, LCLM, UCL, and UCLM; the PLOT statement keywords LCL, LCLM, UCL, and UCLM; and the PLOT statement options CONFi and PRED. Specifying this option in the MODEL statement takes precedence over the ALPHA= option in the PROC REG statement.

B
is used with the RSQUARE, ADJRSQ, and CP model-selection methods to compute estimated regression coefficients for each model selected.

BEST=number
is used with the RSQUARE, ADJRSQ, and CP model-selection methods. If SELECTION=CP or SELECTION=ADJRSQ is specified, the BEST= option specifies the maximum number of subset models to be displayed or output to the OUTEST= data set. For SELECTION=RSQUARE, the BEST= option requests the maximum number of subset models for each size.

If the BEST= option is used without the B option (displaying estimated regression coefficients), the variables in each MODEL are listed in order of inclusion instead of the order in which they appear in the MODEL statement.

If the BEST= option is omitted and the number of regressors is less than 11, all possible subsets are evaluated. If the BEST= option is omitted and the number of regressors is greater than 10, the number of subsets selected is, at most, equal to the number of regressors. A small value of the BEST= option greatly reduces the CPU time required for large problems.

BIC
outputs Sawa’s Bayesian information criterion for each model selected (Sawa 1978; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the BIC statistic is also added to the SubsetSelSummary table.
CLB requests the $100(1 - \alpha)\%$ upper- and lower-confidence limits for the parameter estimates. By default, the 95% limits are computed; the ALPHA= option in the PROC REG or MODEL statement can be used to change the $\alpha$-level.

CLI requests the $100(1 - \alpha)\%$ upper- and lower-confidence limits for an individual predicted value. By default, the 95% limits are computed; the ALPHA= option in the PROC REG or MODEL statement can be used to change the $\alpha$-level. The confidence limits reflect variation in the error, as well as variation in the parameter estimates. See the “Predicted and Residual Values” section on page 3879 and Chapter 2, “Introduction to Regression Procedures,” for more information.

CLM displays the $100(1 - \alpha)\%$ upper- and lower-confidence limits for the expected value of the dependent variable (mean) for each observation. By default, the 95% limits are computed; the ALPHA= in the PROC REG or MODEL statement can be used to change the $\alpha$-level. This is not a prediction interval (see the CLI option) because it takes into account only the variation in the parameter estimates, not the variation in the error term. See the section “Predicted and Residual Values” on page 3879 and Chapter 2 for more information.

COLLIN requests a detailed analysis of collinearity among the regressors. This includes eigenvalues, condition indices, and decomposition of the variances of the estimates with respect to each eigenvalue. See the “Collinearity Diagnostics” section on page 3895.

COLLINOINT requests the same analysis as the COLLIN option with the intercept variable adjusted out rather than included in the diagnostics. See the “Collinearity Diagnostics” section on page 3895.

CORRB displays the correlation matrix of the estimates. This is the $(X'X)^{-1}$ matrix scaled to unit diagonals.

COVB displays the estimated covariance matrix of the estimates. This matrix is $(X'X)^{-1}s^2$, where $s^2$ is the estimated mean squared error.

CP outputs Mallows’ $C_p$ statistic for each model selected (Mallows 1973; Hocking 1976). See the “Criteria Used in Model-Selection Methods” section on page 3876 for a discussion of the use of $C_p$, to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the CP statistic is also added to the SubsetSelSummary table.

DETAILS
DETAILS=name specifies the level of detail produced when the BACKWARD, FORWARD or STEPWISE methods are used, where name can be ALL, STEPS or SUMMARY. The
DETAILS or DETAILS=ALL option produces entry and removal statistics for each variable in the model building process, ANOVA and parameter estimates at each step, and a selection summary table. The option DETAILS=STEPS provides the step information and summary table. The option DETAILS=SUMMARY produces only the summary table. The default if the DETAILS option is omitted is DETAILS=STEPS.

**DW**

Calculates a Durbin-Watson statistic to test whether or not the errors have first-order autocorrelation. (This test is appropriate only for time series data.) The sample autocorrelation of the residuals is also produced. See the section “Autocorrelation in Time Series Data” on page 3915.

**DWPROB**

Calculates a Durbin-Watson statistic and a p-value to test whether or not the errors have first-order autocorrelation. Note that it is not necessary to specify the DW option if the DWPROB option is specified. (This test is appropriate only for time series data.) The sample autocorrelation of the residuals is also produced. See the section “Autocorrelation in Time Series Data” on page 3915.

**EDF**

Outputs the number of regressors in the model excluding and including the intercept, the error degrees of freedom, and the model $R^2$ to the OUTEST= data set.

**GMSEP**

Outputs the estimated mean square error of prediction assuming that both independent and dependent variables are multivariate normal (Stein 1960; Darlington 1968). Note that Hocking’s formula (1976, eq. 4.20) contains a misprint: “$n - 1$” should read “$n - 2$”) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the GMSEP statistic is also added to the SubsetSelSummary table.

**GROUPNAMES=’name1’ ’name2’ . . .**

Provides names for variable groups. This option is available only in the BACKWARD, FORWARD, and STEPWISE methods. The group name can be up to 32 characters. Subsets of independent variables listed in the MODEL statement can be designated as variable groups. This is done by enclosing the appropriate variables in braces. Variables in the same group are entered into or removed from the regression model at the same time. However, if the tolerance of any variable (see the TOL option on page 3832) in a group is less than the setting of the SINGULAR= option, then the variable is not entered into the model with the rest of its group. If the GROUPNAMES= option is not used, then the names GROUP1, GROUP2, . . ., GROUPn are assigned to groups encountered in the MODEL statement. Variables not enclosed by braces are used as groups of a single variable.

For example,

```
model y={x1 x2} x3 / selection=stepwise
groupnames='x1 x2' 'x3';
```
As another example,

```plaintext
model y={ht wgt age} bodyfat / selection=forward
groupnames='htwgtage' 'bodyfat';
```

I displays the \((X'X)^{-1}\) matrix. The inverse of the crossproducts matrix is bordered by the parameter estimates and SSE matrices.

**INCLUDE=n**

forces the first \(n\) independent variables listed in the MODEL statement to be included in all models. The selection methods are performed on the other variables in the MODEL statement. The INCLUDE= option is not available with SELECTION=NONE.

**INFLUENCE**

requests a detailed analysis of the influence of each observation on the estimates and the predicted values. See the “Influence Diagnostics” section on page 3898 for details.

**JP**

outputs \(J_p\), the estimated mean square error of prediction for each model selected assuming that the values of the regressors are fixed and that the model is correct to the OUTEST= data set. The \(J_p\) statistic is also called the final prediction error (FPE) by Akaike (Nicholson 1948; Lord 1950; Mallows 1967; Darlington 1968; Rothman 1968; Akaike 1969; Hocking 1976; Judge et al. 1980). If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the \(J_p\) statistic is also added to the SubsetSelSummary table.

**MSE**

computes the mean square error for each model selected (Darlington 1968).

**MAXSTEP=n**

specifies the maximum number of steps that are done when SELECTION=FORWARD, SELECTION=BACKWARD or SELECTION=STEPWISE is used. The default value is the number of independent variables in the model for the forward and backward methods and three times this number for the stepwise method.

**NOINT**

suppresses the intercept term that is otherwise included in the model.

**NOPRINT**

suppresses the normal display of regression results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.
OUTSEB
outputs the standard errors of the parameter estimates to the OUTEST= data set. The value SEB for the variable _TYPE_ identifies the standard errors. If the RIDGE= or PCOMIT= option is specified, additional observations are included and identified by the values RIDGESEB and IPCSEB, respectively, for the variable _TYPE_. The standard errors for ridge regression estimates and incomplete principal components (IPC) estimates are limited in their usefulness because these estimates are biased. This option is available for all model-selection methods except RSQUARE, ADJRSQ, and CP.

OUTSTB
outputs the standardized parameter estimates as well as the usual estimates to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The values RIDGESTB and IPCSTB for the variable _TYPE_ identify ridge regression estimates and IPC estimates, respectively.

OUTVIF
outputs the variance inflation factors (VIF) to the OUTEST= data set when the RIDGE= or PCOMIT= option is specified. The factors are the diagonal elements of the inverse of the correlation matrix of regressors as adjusted by ridge regression or IPC analysis. These observations are identified in the output data set by the values RIDGEVIF and IPCVIF for the variable _TYPE_.

P
calculates predicted values from the input data and the estimated model. The display includes the observation number, the ID variable (if one is specified), the actual and predicted values, and the residual. If the CLI, CLM, or R option is specified, the P option is unnecessary. See the section “Predicted and Residual Values” on page 3879 for more information.

PARTIAL
requests partial regression leverage plots for each regressor. If ODS Graphics are in effect (see the “ODS Graphics” section on page 3922), then these partial plots are produced in panels with up to six plots per panel. See the “Influence Diagnostics” section on page 3898 for more information.

PARTIALR2 < ( < TESTS > < SEQTESTS > ) >
See the SCORR1 option.

PC
outputs Amemiya’s prediction criterion for each model selected (Amemiya 1976; Judge et al. 1980) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE, or SELECTION=CP is specified, then the PC statistic is also added to the SubsetSelSummary table.

PCOMIT=list
requests an IPC analysis for each value m in the list. The procedure computes parameter estimates using all but the last m principal components. Each value of m produces a set of IPC estimates, which is output to the OUTEST= data set. The values of m are saved by the variable _PCOMIT_, and the value of the variable _TYPE_ is set
to IPC to identify the estimates. Only nonnegative integers can be specified with the
PCOMIT= option.

If you specify the PCOMIT= option, RESTRICT statements are ignored. The
PCOMIT= option is ignored if you use the SELECTION= option in the MODEL
statement.

PCORR1
displays the squared partial correlation coefficients using Type I Sum of Squares (SS).
This is calculated as SS/(SS+SSE), where SSE is the error Sum of Squares.

PCORR2
displays the squared partial correlation coefficients using Type II sums of squares.
These are calculated the same way as with the PCORR1 option, except that Type II
SS are used instead of Type I SS.

PRESS
outputs the PRESS statistic to the OUTEST= data set. The values of this statistic
are saved in the variable _PRESS_. This option is available for all model-selection
methods except RSQUARE, ADJRSQ, and CP.

R
requests an analysis of the residuals. The results include everything requested by the
P option plus the standard errors of the mean predicted and residual values, the stu-
dentized residual, and Cook’s D statistic to measure the influence of each observation
on the parameter estimates. See the section “Predicted and Residual Values” on page
3879 for more information.

RIDGE=list
requests a ridge regression analysis and specifies the values of the ridge constant
k (see the “Computations for Ridge Regression and IPC Analysis” section on page
3916). Each value of k produces a set of ridge regression estimates that are placed in
the OUTEST= data set. The values of k are saved by the variable _RIDGE_, and the
value of the variable _TYPE_ is set to RIDGE to identify the estimates.

Only nonnegative numbers can be specified with the RIDGE= option. Example 61.10
on page 3956 illustrates this option.

If you specify the RIDGE= option, RESTRICT statements are ignored. The RIDGE=
option is ignored if you use the SELECTION= option in the MODEL statement.

RMSE
displays the root mean square error for each model selected.

RSQUARE
has the same effect as the EDF option.

SBC
outputs the SBC statistic for each model selected (Schwarz 1978; Judge et al. 1980)
to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=RSQUARE,
or SELECTION=CP is specified, then the SBC statistic is also added to the
SubsetSelSummary table.
SCORR1 < ( < TESTS > < SEQTESTS > ) >
displays the squared semi-partial correlation coefficients using Type I sums of squares. This is calculated as SS/SST, where SST is the corrected total SS. If the NOINT option is used, the uncorrected total SS is used in the denominator. The optional arguments TESTS and SEQTESTS request F-tests, p-values, and cumulative R-Square values as variables are sequentially added to a model. The F-test values are computed as the Type I sum of squares for the variable in question divided by a mean square error. If you specify the TESTS option, the denominator MSE is the residual mean square for the full model specified in the MODEL statement. If you specify the SEQTESTS option, the denominator MSE is the residual mean square for the model containing all the independent variables that have been added to the model up to and including the variable in question. The TESTS and SEQTESTS options are not supported if you specify model selection methods, or the RIDGE or PCOMIT options. Note that the PARTIALR2 option is a synonym for the SCORR1 option.

SCORR2 < ( TESTS ) >
displays the squared semi-partial correlation coefficients using Type II sums of squares. These are calculated the same way as with the SCORR1 option, except that Type II SS are used instead of Type I SS. The optional TEST argument requests F-tests and p-values as variables are sequentially added to a model. The F-test values are computed as the Type II sum of squares for the variable in question divided by the residual mean square for the full model specified in the MODEL statement. The TESTS option is not supported if you specify model selection methods, or the RIDGE or PCOMIT options.

SELECTION=name
specifies the method used to select the model, where name can be FORWARD (or F), BACKWARD (or B), STEPWISE, MAXR, MINR, RSQUARE, ADJRSQ, CP, or NONE (use the full model). The default method is NONE. See the “Model-Selection Methods” section on page 3873 for a description of each method.

SEQB
produces a sequence of parameter estimates as each variable is entered into the model. This is displayed as a matrix where each row is a set of parameter estimates.

SIGMA=n
specifies the true standard deviation of the error term to be used in computing the CP and BIC statistics. If the SIGMA= option is not specified, an estimate from the full model is used. This option is available in the RSQUARE, ADJRSQ, and CP model-selection methods only.

SINGULAR=n
tunes the mechanism used to check for singularities. Specifying this option in the MODEL statement takes precedence over the SINGULAR= option in the PROC REG statement. The default value is machine dependent but is approximately 1E–7 on most machines. This option is rarely needed. Singularity checking is described in the “Computational Methods” section on page 3917.
**SLENTRY=** value  
**SLE=** value  
specifies the significance level for entry into the model used in the FORWARD and STEPWISE methods. The defaults are 0.50 for FORWARD and 0.15 for STEPWISE.

**SLSTAY=** value  
**SLS=** value  
specifies the significance level for staying in the model for the BACKWARD and STEPWISE methods. The defaults are 0.10 for BACKWARD and 0.15 for STEPWISE.

**SP**  
outputs the $S_p$ statistic for each model selected (Hocking 1976) to the OUTEST= data set. If SELECTION=ADJRSQ, SELECTION=R-square, or SELECTION=CP is specified, then the SP statistic is also added to the SubsetSelSummary table.

**SPEC**  
performs a test that the first and second moments of the model are correctly specified. See the section “Testing for Heteroscedasticity” on page 3910 for more information.

**SS1**  
displays the sequential sums of squares (Type I SS) along with the parameter estimates for each term in the model. See Chapter 11, “The Four Types of Estimable Functions,” for more information on the different types of sums of squares.

**SS2**  
displays the partial sums of squares (Type II SS) along with the parameter estimates for each term in the model. See the **SS1** option also.

**SSE**  
computes the error sum of squares for each model selected.

**START=** s  
is used to begin the comparing-and-switching process in the MAXR, MINR, and STEPWISE methods for a model containing the first $s$ independent variables in the MODEL statement, where $s$ is the START value. For these methods, the default is START=0.

For the RSQUARE, ADJRSQ, and CP methods, **START=** s specifies the smallest number of regressors to be reported in a subset model. For these methods, the default is START=1.

The **START=** option cannot be used with model-selection methods other than the six described here.

**STB**  
produces standardized regression coefficients. A standardized regression coefficient is computed by dividing a parameter estimate by the ratio of the sample standard deviation of the dependent variable to the sample standard deviation of the regressor.
STOP=s
causes PROC REG to stop when it has found the “best” s-variable model, where s is the STOP value. For the RSQUARE, ADJRSQ, and CP methods, STOP=s specifies the largest number of regressors to be reported in a subset model. For the MAXR and MINR methods, STOP=s specifies the largest number of regressors to be included in the model.

The default setting for the STOP= option is the number of variables in the MODEL statement. This option can be used only with the MAXR, MINR, RSQUARE, ADJRSQ and CP methods.

TOL
produces tolerance values for the estimates. Tolerance for a variable is defined as 1 – $R^2$, where $R^2$ is obtained from the regression of the variable on all other regressors in the model. See the section “Collinearity Diagnostics” on page 3895 for more detail.

VIF
produces variance inflation factors with the parameter estimates. Variance inflation is the reciprocal of tolerance. See the section “Collinearity Diagnostics” on page 3895 for more detail.

XPX
displays the $X'X$ crossproducts matrix for the model. The crossproducts matrix is bordered by the $X'Y$ and $Y'Y$ matrices.

**MTEST Statement**

```plaintext
< label: > MTEST < equation , . . . , equation > < / options > ;
```

where each equation is a linear function composed of coefficients and variable names. The label is optional.

The MTEST statement is used to test hypotheses in multivariate regression models where there are several dependent variables fit to the same regressors. If no equations or options are specified, the MTEST statement tests the hypothesis that all estimated parameters except the intercept are zero.

The hypotheses that can be tested with the MTEST statement are of the form

$$(L\beta - c^j)M = 0$$

where $L$ is a linear function on the regressor side, $\beta$ is a matrix of parameters, $c$ is a column vector of constants, $j$ is a row vector of ones, and $M$ is a linear function on the dependent side. The special case where the constants are zero is

$$L\beta M = 0$$

See the section “Multivariate Tests” on page 3910 for more details.

Each linear function extends across either the regressor variables or the dependent variables. If the equation is across the dependent variables, then the constant term, if
specified, must be zero. The equations for the regressor variables form the $L$ matrix and $c$ vector in the preceding formula; the equations for dependent variables form the $M$ matrix. If no equations for the dependent variables are given, PROC REG uses an identity matrix for $M$, testing the same hypothesis across all dependent variables. If no equations for the regressor variables are given, PROC REG forms a linear function corresponding to a test that all the nonintercept parameters are zero.

As an example, consider the following statements:

```plaintext
model y1 y2 y3=x1 x2 x3;
mtest x1,x2;
mtest y1-y2, y2 -y3, x1;
mtest y1-y2;
```

The first MTEST statement tests the hypothesis that the $X_1$ and $X_2$ parameters are zero for $Y_1$, $Y_2$ and $Y_3$. In addition, the second MTEST statement tests the hypothesis that the $X_1$ parameter is the same for all three dependent variables. For the same model, the third MTEST statement tests the hypothesis that all parameters except the intercept are the same for dependent variables $Y_1$ and $Y_2$.

You can specify the following options in the MTEST statement.

**CANPRINT**

- displays the canonical correlations for the hypothesis combinations and the dependent variable combinations. If you specify

  ```plaintext
  mtest / canprint;
  ```

  the canonical correlations between the regressors and the dependent variables are displayed.

**DETAILS**

- displays the $M$ matrix and various intermediate calculations.

**PRINT**

- displays the $H$ and $E$ matrices.

### OUTPUT Statement

**OUTPUT** `< OUT=SAS-data-set > keyword=names` `< ... keyword=names > ;`

The OUTPUT statement creates a new SAS data set that saves diagnostic measures calculated after fitting the model. The OUTPUT statement refers to the most recent MODEL statement. At least one `keyword=names` specification is required.

All the variables in the original data set are included in the new data set, along with variables created in the OUTPUT statement. These new variables contain the values of a variety of statistics and diagnostic measures that are calculated for each observation in the data set. If you want to create a permanent SAS data set, you must specify
a two-level name (for example, libref.data-set-name). For more information on permanent SAS data sets, refer to the section “SAS Files” in SAS Language Reference: Concepts.

The OUTPUT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. See the “Input Data Sets” section on page 3860 for more details.

The statistics created in the OUTPUT statement are described in this section. More details are contained in the “Predicted and Residual Values” section on page 3879 and the “Influence Diagnostics” section on page 3898. Also see Chapter 2, “Introduction to Regression Procedures,” for definitions of the statistics available from the REG procedure.

You can specify the following options in the OUTPUT statement.

**OUT=SAS data set**

gives the name of the new data set. By default, the procedure uses the DATA convention to name the new data set.

**keyword=names**

specifies the statistics to include in the output data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable or variables to contain the statistic.

In the output data set, the first variable listed after a keyword in the OUTPUT statement contains that statistic for the first dependent variable listed in the MODEL statement; the second variable contains the statistic for the second dependent variable in the MODEL statement, and so on. The list of variables following the equal sign can be shorter than the list of dependent variables in the MODEL statement. In this case, the procedure creates the new names in order of the dependent variables in the MODEL statement.

For example, the SAS statements

```
proc reg data=a;
  model y z=x1 x2;
  output out=b
    p=yhat zhat
    r=yresid zresid;
run;
```

create an output data set named b. In addition to the variables in the input data set, b contains the following variables:

- yhat, with values that are predicted values of the dependent variable y
- zhat, with values that are predicted values of the dependent variable z
- yresid, with values that are the residual values of y
- zresid, with values that are the residual values of z
You can specify the following keywords in the OUTPUT statement. See the “Model Fit and Diagnostic Statistics” section on page 3896 for computational formulas.

Table 61.3. Keywords for OUTPUT Statement

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COOKD=names</td>
<td>Cook’s $D$ influence statistic</td>
</tr>
<tr>
<td>COVRATIO=names</td>
<td>standard influence of observation on covariance of betas, as discussed in the “Influence Diagnostics” section on page 3898</td>
</tr>
<tr>
<td>DFFITS=names</td>
<td>standard influence of observation on predicted value</td>
</tr>
<tr>
<td>H=names</td>
<td>leverage, $x_i^t(X^tX)^{-1}x_i$</td>
</tr>
<tr>
<td>LCL=names</td>
<td>lower bound of a 100(1 − $\alpha$)% confidence interval for an individual prediction. This includes the variance of the error, as well as the variance of the parameter estimates.</td>
</tr>
<tr>
<td>LCLM=names</td>
<td>lower bound of a 100(1 − $\alpha$)% confidence interval for the expected value (mean) of the dependent variable</td>
</tr>
<tr>
<td>PREDICTED</td>
<td>P=names</td>
</tr>
<tr>
<td>PRESS=names</td>
<td>$i$th residual divided by $(1 - h)$, where $h$ is the leverage, and where the model has been refit without the $i$th observation</td>
</tr>
<tr>
<td>RESIDUAL</td>
<td>R=names</td>
</tr>
<tr>
<td>RSTUDENT=names</td>
<td>a studentized residual with the current observation deleted</td>
</tr>
<tr>
<td>STDI=names</td>
<td>standard error of the individual predicted value</td>
</tr>
<tr>
<td>STDP=names</td>
<td>standard error of the mean predicted value</td>
</tr>
<tr>
<td>STDR=names</td>
<td>standard error of the residual</td>
</tr>
<tr>
<td>STUDENT=names</td>
<td>studentized residuals, which are the residuals divided by their standard errors</td>
</tr>
<tr>
<td>UCL=names</td>
<td>upper bound of a 100(1 − $\alpha$)% confidence interval for an individual prediction</td>
</tr>
<tr>
<td>UCLM=names</td>
<td>upper bound of a 100(1 − $\alpha$)% confidence interval for the expected value (mean) of the dependent variable</td>
</tr>
</tbody>
</table>

**PAINT Statement**

PAINT < condition | ALLOBS > < / options > ;
PAINT < STATUS | UNDO > ;

The PAINT statement selects observations to be painted or highlighted in a scatter plot on line printer output; the PAINT statement is ignored if the LINEPRINTER option is not specified in the PROC REG statement.

All observations that satisfy condition are painted using some specific symbol. The PAINT statement does not generate a scatter plot and must be followed by a PLOT statement, which does generate a scatter plot. Several PAINT statements can be used before a PLOT statement, and all prior PAINT statement requests are applied to all later PLOT statements.
The PAINT statement lists the observation numbers of the observations selected, the total number of observations selected, and the plotting symbol used to paint the points.

On a plot, paint symbols take precedence over all other symbols. If any position contains more than one painted point, the paint symbol for the observation plotted last is used.

The PAINT statement cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set for PROC REG. Also, the PAINT statement cannot be used for models with more than one dependent variable. Note that the syntax for the PAINT statement is the same as the syntax for the REWEIGHT statement.

For detailed examples of painting scatter plots, see the section “Painting Scatter Plots” on page 3889.

**Specifying Condition**

Condition is used to select observations to be painted. The syntax of condition is

\[
\text{variable compare value}
\]

or

\[
\text{variable compare value logical variable compare value}
\]

where

- **variable** is one of the following:
  - a variable name in the input data set
  - OBS., which is the observation number
  - keyword., where keyword is a keyword for a statistic requested in the OUTPUT statement

- **compare** is an operator that compares variable to value. Compare can be any one of the following: <, <=, >, >=, =, ^=. The operators LT, LE, GT, GE, EQ, and NE can be used instead of the preceding symbols. Refer to the “Expressions” section in *SAS Language Reference: Concepts* for more information on comparison operators.

- **value** gives an unformatted value of variable. Observations are selected to be painted if they satisfy the condition created by variable compare value. Value can be a number or a character string. If value is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, value is case-sensitive. In other words, the statements

\[
\text{paint name='henry';}
\]

and
**Paint Statement**

```plaintext
paint name='Henry';
```

are not the same.

*logical* is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Examples of the *variable compare value* form are

```plaintext
paint name='Henry';
paint residual.>=20;
paint obs.=99;
```

Examples of the *variable compare value* *logical* *variable compare value* form are

```plaintext
paint name='Henry'|name='Mary';
paint residual.>=20 or residual.<=10;
paint obs.>=11 and residual.<=20;
```

**Using ALLOBS**

Instead of specifying *condition*, the ALLOBS option can be used to select all observations. This is most useful when you want to unpaint all observations. For example,

```plaintext
paint allobs / reset;
```

resets the symbols for all observations.

**Options in the Paint Statement**

The following options can be used when either a condition is specified, the ALLOBS option is specified, or when nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous PAINT statement, *not* to the observations selected by reapplying the condition from the previous PAINT statement. For example, in the statements

```plaintext
paint r.>0 / symbol='a';
reweight r.>0;
refit;
paint / symbol='b';
```

the second PAINT statement paints only those observations selected in the first PAINT statement. No additional observations are painted even if, after refitting the model, there are new observations that meet the condition in the first PAINT statement.

**Note:** Options are not available when either the UNDO or STATUS option is used.
You can specify the following options after a slash (/).

**NOLIST**  
suppresses the display of the selected observation numbers. If the NOLIST option is not specified, a list of observations selected is written to the log. The list includes the observation numbers and painting symbol used to paint the points. The total number of observations selected to be painted is also shown.

**RESET**  
changes the painting symbol to the current default symbol, effectively unpainting the observations selected. If you set the default symbol by using the SYMBOL= option in the PLOT statement, the RESET option in the PAINT statement changes the painting symbol to the symbol you specified. Otherwise, the default symbol of ’1’ is used.

**SYMBOL = 'character’**  
specifies a painting symbol. If the SYMBOL= option is omitted, the painting symbol is either the one used in the most recent PAINT statement or, if there are no previous PAINT statements, the symbol ’@’. For example,

```plaintext
paint / symbol='#';
```

changes the painting symbol for the observations selected by the most recent PAINT statement to ’#’. As another example,

```plaintext
paint temp lt 22 / symbol='c';
```

changes the painting symbol to ’c’ for all observations with TEMP<22. In general, the numbers 1, 2, . . . , 9 and the asterisk are not recommended as painting symbols. These symbols are used as default symbols in the PLOT statement, where they represent the number of replicates at a point. If SYMBOL=” is used, no painting is done in the current plot. If SYMBOL=' ' is used, observations are painted with a blank and are no longer seen on the plot.

**STATUS and UNDO**  
Instead of specifying condition or the ALLOBS option, you can use the STATUS or UNDO option as follows:

**STATUS**  
lists (on the log) the observation number and plotting symbol of all currently painted observations.

**UNDO**  
undoes changes made by the most recent PAINT statement. Observations may be, but are not necessarily, unpainted. For example,

```plaintext
paint obs. <=10 / symbol='a';

...other interactive statements
paint obs.=1 / symbol='b';

...other interactive statements
paint undo;
```
The last PAINT statement changes the plotting symbol used for observation 1 back to ‘a’. If the statement

```
paint / reset;
```

is used instead, observation 1 is unpainted.

### PLOT Statement

The PLOT statement in PROC REG displays scatter plots with `yvariable` on the vertical axis and `xvariable` on the horizontal axis. Line printer plots are generated if the LINEPRINTER option is specified in the PROC REG statement; otherwise, the traditional high-resolution graphics plots are created. Points in line printer plots can be marked with `symbols`, while global graphics statements such as GOPTIONS and SYMBOL are used to enhance the high-resolution graphics plots. Note that the plots you request using the PLOT statement are independent of the experimental ODS graphics (see the “ODS Graphics” section on page 3922) that are now available in PROC REG.

As with most other interactive statements, the PLOT statement implicitly refits the model. For example, if a PLOT statement is preceded by a REWEIGHT statement, the model is recomputed, and the plot reflects the new model.

If there are multiple MODEL statements preceding a PLOT statement, then the PLOT statement refers to the latest MODEL statement.

The PLOT statement cannot be used when TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets are used as input to PROC REG.

You can specify several PLOT statements for each MODEL statement, and you can specify more than one plot in each PLOT statement. For detailed examples of using the PLOT statement and its options, see the section “Producing Scatter Plots” on page 3882.

### Specifying Yvariables, Xvariables, and Symbol

More than one `yvariable*xvariable` pair can be specified to request multiple plots. The `yvariables` and `xvariables` can be

- any variables specified in the VAR or MODEL statement before the first RUN statement
- `keyword`, where `keyword` is a regression diagnostic statistic available in the OUTPUT statement (see Table 61.4 on page 3842). For example,

```
plot predicted.*residual.;
```
Chapter 61. The REG Procedure

generates one plot of the predicted values by the residuals for each dependent variable in the MODEL statement. These statistics can also be plotted against any of the variables in the VAR or MODEL statements.

• the keyword OBS. (the observation number), which can be plotted against any of the preceding variables

• the keyword NPP. or NQQ., which can be used with any of the preceding variables to construct normal P-P or Q-Q plots, respectively (see the section “Construction of Q-Q and P-P Plots” on page 3917 and Example 61.8 on page 3953 for more information)

• keywords for model fit summary statistics available in the OUTEST= data set with _TYPE_= PARMS (see Table 61.4 on page 3842). A SELECTION= method (other than NONE) must be requested in the MODEL statement for these variables to be plotted. If one member of a yvariable*xvariable pair is from the OUTEST= data set, the other member must also be from the OUTEST= data set.

The OUTPUT statement and the OUTEST= option are not required when their keywords are specified in the PLOT statement.

The yvariable and xvariable specifications can be replaced by a set of variables and statistics enclosed in parentheses. When this occurs, all possible combinations of yvariable and xvariable are generated. For example, the following two statements are equivalent.

```
plot (y1 y2)*(x1 x2);
plot y1*x1 y1*x2 y2*x1 y2*x2;
```

The statement

```
plot;
```

is equivalent to respecifying the most recent PLOT statement without any options. However, the line printer options COLLECT, HPLOTS=, SYMBOL=, and VPLOTS=, described in the “Line Printer Plots” section on page 3848, apply across PLOT statements and remain in effect if they have been previously specified.

Options used for the traditional high-resolution graphics plots are described in the following section; see for more information.

**Traditional High-Resolution Graphics Plots**

The display of high-resolution graphics plots is described in the following paragraphs, the options are summarized in Table 61.4 and described in the section “Dictionary of PLOT Statement Options” on page 3844, and the “Examples” section on page 3924 contains several examples of the graphics output.

Several line printer statements and options are not supported for high-resolution graphics. In particular the PAINT statement is disabled, as are the PLOT statement options CLEAR, COLLECT, HPLOTS=, NOCOLLECT, SYMBOL=, and
VPLOTS=. To display more than one plot per page or to collect plots from multiple PLOT statements, use the PROC GREPLAY statement (refer to SAS/GRAPH Software: Reference). Also note that high-resolution graphics options are not recognized for line printer plots.

The fitted model equation and a label are displayed in the top margin of the plot; this display can be suppressed with the NOMODEL option. If the label is requested but cannot fit on one line, it is not displayed. The equation and label are displayed on one line when possible; if more lines are required, the label is displayed in the first line with the model equation in successive lines. If displaying the entire equation causes the plot to be unacceptably small, the equation is truncated. Table 61.5 on page 3843 lists options to control the display of the equation. The “Examples” section on page 3924 illustrates the display of the model equation.

Four statistics are displayed by default in the right margin: the number of observations, $R^2$, the adjusted $R^2$, and the root mean square error. (See Output 61.4.1 on page 3949.) The display of these statistics can be suppressed with the NOSTAT option. You can specify other options to request the display of various statistics in the right margin; see Table 61.5 on page 3843.

A default reference line at zero is displayed if residuals are plotted; see Output 61.7.1 on page 3952. If the dependent variable is plotted against the independent variable in a simple linear regression model, the fitted regression line is displayed by default. (See Output 61.4.1 on page 3949.) Default reference lines can be suppressed with the NOLINE option; the lines are not displayed if the OVERLAY option is specified.

Specialized plots are requested with special options. For each coefficient, the RIDGEPLOT option plots the ridge estimates against the ridge values $k$; see the description of the RIDGEPLOT option in the section “Dictionary of PLOT Statement Options” beginning on page 3844 and Example 61.10 on page 3956 for more details. The CONF option plots $100(1 - \alpha)\%$ confidence intervals for the mean while the PRED option plots $100(1 - \alpha)\%$ prediction intervals; see the description of these options in the section “Dictionary of PLOT Statement Options” beginning on page 3844 and in Example 61.9 on page 3955 for more details.

If a SELECTION= method is requested, the fitted model equation and the statistics displayed in the margin correspond to the selected model. For the ADJRSQ and CP methods, the selected model is treated as a submodel of the full model. If a CP.*NP. plot is requested, the CHOCKING= and CMALLOWS= options display model selection reference lines; see the descriptions of these options in the section “Dictionary of PLOT Statement Options” beginning on page 3844 and Example 61.5 on page 3949 for more details.

**PLOT Statement variable Keywords**

The following table lists the keywords available as PLOT statement xvariables and yvariables. All keywords have a trailing dot; for example, “COOKD.” requests Cook’s D statistic. Neither the OUTPUT statement nor the OUTEST= option needs to be specified.
Table 61.4. Keywords for PLOT Statement xvariables and yvariables

</table>

**Dictionary of PLOT Statement Options**

The following entries describe the PLOT statement options in detail. Note that these options are available unless you specify the LINEPRINTER option in the PROC REG statement.

**AIC**

- displays Akaike’s information criterion in the plot margin.

**ANNOTATE=SAS-data-set**

- specifies an input data set that contains appropriate variables for annotation. This applies only to displays created with the current PLOT statement. Refer to *SAS/GRAPH Software: Reference* for more information.

**BIC**

- displays Sawa’s Bayesian information criterion in the plot margin.

**CAXIS=color**

**CAXES=color**

**CA=color**

- specifies the color for the axes, frame, and tick marks.

**CFRAME=color**

**CFR=color**

- specifies the color for filling the area enclosed by the axes and the frame.
CHOCKING=color
requests reference lines corresponding to the equations $C_p = p$ and $C_p = 2p - p_{\text{full}}$, where $p_{\text{full}}$ is the number of parameters in the full model (excluding the intercept) and $p$ is the number of parameters in the subset model (including the intercept). The color must be specified; the $C_p = p$ line is solid and the $C_p = 2p - p_{\text{full}}$ line is dashed. Only PLOT statements of the form PLOT CP.*NP. produce these lines.

For the purpose of parameter estimation, Hocking (1976) suggests selecting a model where $C_p \leq 2p - p_{\text{full}}$. For the purpose of prediction, Hocking suggests the criterion $C_p \leq p$. You can request the single reference line $C_p = p$ with the CMALLOWS= option. If, for example, you specify both CHOCKING=RED and CMALLOWS=BLUE, then the $C_p = 2p - p_{\text{full}}$ line is red and the $C_p = p$ line is blue (see Example 61.5 on page 3949).

CHREF=color
CH=color
specifies the color for lines requested with the HREF= option.

CLINE=color
CL=color
specifies the color for lines displayed by default. See the NOLINE option later in this section for details.

CMALLOWS=color
requests a $C_p = p$ reference line, where $p$ is the number of parameters (including the intercept) in the subset model. The color must be specified; the line is solid. Only PLOT statements of the form PLOT CP.*NP. produce this line.

Mallows (1973) suggests that all subset models with $C_p$ small and near $p$ be considered for further study. See the CHOCKING= option for related model selection criteria.

CONF
is a keyword used as a shorthand option to request plots that include $(100 - \alpha)\%$ confidence intervals for the mean response (see Example 61.9 on page 3955). The ALPHA= option in the PROC REG or MODEL statement selects the significance level $\alpha$, which is 0.05 by default. The CONF option is valid for simple regression models only, and is ignored for plots where confidence intervals are inappropriate. The CONF option replaces the CONF95 option; however, the CONF95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the CONF option is specified.

CP
displays Mallows’ $C_p$ statistic in the plot margin.

CTEXT=color
CT=color
specifies the color for text including tick mark labels, axis labels, the fitted model label and equation, the statistics displayed in the margin, and legends. (See Example 61.6 on page 3950.)
CVREF=color
CV=color
specifies the color for lines requested with the VREF= option.

DESCRIPTION='string'
DESC='string'
specifies a descriptive string, up to 40 characters, that appears in the description field of the PROC GREATEPLAY master menu.

EDF
displays the error degrees of freedom in the plot margin.

GMSEP
displays the estimated mean square error of prediction in the plot margin. Note that the estimate is calculated under the assumption that both independent and dependent variables have a multivariate normal distribution.

HAXIS=values
HA=values
specifies tick mark values for the horizontal axis.

HREF=values
specifies where reference lines perpendicular to the horizontal axis are to appear.

IN
displays the number of regressors in the model (not including the intercept) in the plot margin.

JP
displays the Jp statistic in the plot margin.

LEGEND=LEGENDn
specifies the LEGENDn statement to be used. The LEGENDn statement is a global graphics statement; refer to SAS/GRAPH Software: Reference for more information.

LHREF=linetype
LH=linetype
specifies the line style for lines requested with the HREF= option. The default linetype is 2. Note that LHREF=1 requests a solid line. Refer to SAS/GRAPH Software: Reference for a table of available line types.

LLINE=linetype
LL=linetype
specifies the line style for reference lines displayed by default; see the NOLINE option for details. The default linetype is 2. Note that LLINE=1 requests a solid line.

LVREF=linetype
LV=linetype
specifies the line style for lines requested with the VREF= option. The default linetype is 2. Note that LVREF=1 requests a solid line.

MODELFONT=font
specifies the font used for displaying the fitted model label and the fitted model equa-
PLOT Statement

♦

MODELHT=height
specifies the text height for the fitted model label and the fitted model equation.

MODELLAB='label'
specifies the label to be displayed with the fitted model equation. By default, no label is displayed. If the label does not fit on one line, it is not displayed. See the explanation in the section “Traditional High-Resolution Graphics Plots” beginning on page 3840 for more information.

MSE
displays the mean squared error in the plot margin.

NAME='string'
specifies a descriptive string, up to eight characters, that appears in the name field of the PROC GREPLAY master menu. The default string is REG.

NOLINE
suppresses the display of default reference lines. A default reference line at zero is displayed if residuals are plotted. If the dependent variable is plotted against the independent variable in a simple regression model, then the fitted regression line is displayed by default. Default reference lines are not displayed if the OVERLAY option is specified.

NOMODEL
suppresses the display of the fitted model equation.

NOSTAT
suppresses the display of statistics in the plot margin. By default, the number of observations, R-square, adjusted R-square, and the root MSE are displayed.

NP
displays the number of regressors in the model including the intercept, if any, in the plot margin.

OVERLAY
overlays all plots specified in the PLOT statement from the same model on one set of axes. The variables for the first plot label the axes. The procedure automatically scales the axes to fit all of the variables unless the HAXIS= or VAXIS= option is used. Default reference lines are not displayed. A default legend is produced; the LEGEND= option can be used to customize the legend. See Example 61.11 on page 3958.

PC
displays the PC statistic in the plot margin.

PRED
is a keyword used as a shorthand option to request plots that include \((100 - \alpha)\)% prediction intervals for individual responses (see Example 61.9 on page 3955). The ALPHA= option in the PROC REG or MODEL statement selects the significance level \(\alpha\), which is 0.05 by default. The PRED option is valid for simple regression models only, and is ignored for plots where prediction intervals are inappropriate.
The PRED option replaces the PRED95 option; however, the PRED95 option is still supported when the ALPHA= option is not specified. The OVERLAY option is ignored when the PRED option is specified.

**RIDGEPLOT**

creates overlaid plots of ridge estimates against ridge values for each coefficient. The points corresponding to the estimates of each coefficient in the plot are connected by lines. For ridge estimates to be computed and plotted, the OUTEST= option must be specified in the PROC REG statement, and the RIDGE= list must be specified in either the PROC REG or the MODEL statement. See Example 61.10 on page 3956.

**SBC**

displays the SBC statistic in the plot margin.

**SP**

displays the $S_p$ statistic in the plot margin.

**SSE**

displays the error sum of squares in the plot margin.

**STATFONT=** *font*

specifies the font used for displaying the statistics that appear in the plot margin. Refer to SAS/GRAPH Software: Reference for tables of software fonts.

**STATHT=** *height*

specifies the text height of the statistics that appear in the plot margin.

**USEALL**

specifies that predicted values at data points with missing dependent variable(s) are included on appropriate plots. By default, only points used in constructing the SSCP matrix appear on plots.

**VAXIS=** *values*  

**VA=** *values*

specifies tick mark values for the vertical axis.

**VREF=** *values*

specifies where reference lines perpendicular to the vertical axis are to appear.

**Line Printer Plots**

Line printer plots are requested with the LINEPRINTER option in the PROC REG statement. Points in line printer plots can be marked with *symbols*, which can be specified as a single character enclosed in quotes or the name of any variable in the input data set.

If a character variable is used for the symbol, the first (left-most) nonblank character in the formatted value of the variable is used as the plotting symbol. If a character in quotes is specified, that character becomes the plotting symbol. If a character is used as the plotting symbol, and if there are different plotting symbols needed at the same point, the symbol ‘?’ is used at that point.

If an unformatted numeric variable is used for the symbol, the symbols ‘1’, ‘2’, . . . , ‘9’ are used for variable values 1, 2, . . . , 9. For noninteger values, only the integer
portion is used as the plotting symbol. For values of 10 or greater, the symbol ‘*’ is used. For negative values, a ‘?’ is used. If a numeric variable is used, and if there is more than one plotting symbol needed at the same point, the sum of the variable values is used at that point. If the sum exceeds 9, the symbol ‘*’ is used.

If a symbol is not specified, the number of replicates at the point is displayed. The symbol ‘*’ is used if there are ten or more replicates.

If the LINEPRINTER option is used, you can specify the following options in the PLOT statement after a slash (/):

CLEAR
clears any collected scatter plots before plotting begins but does not turn off the COLLECT option. Use this option when you want to begin a new collection with the plots in the current PLOT statement. For more information on collecting plots, see the COLLECT and NOCOLLECT options in this section.

COLLECT
specifies that plots begin to be collected from one PLOT statement to the next and that subsequent plots show an overlay of all collected plots. This option enables you to overlay plots before and after changes to the model or to the data used to fit the model. Plots collected before changes are unaffected by the changes and can be overlaid on later plots. You can request more than one plot with this option, and you do not need to request the same number of plots in subsequent PLOT statements. If you specify an unequal number of plots, plots in corresponding positions are overlaid. For example, the statements

```
plot residual.*predicted. y*x / collect;
run;
```

produce two plots. If these statements are then followed by

```
plot residual.*x;
run;
```

two plots are again produced. The first plot shows residual against X values overlaid on residual against predicted values. The second plot is the same as that produced by the first PLOT statement.

Axes are scaled for the first plot or plots collected. The axes are not rescaled as more plots are collected.

Once specified, the COLLECT option remains in effect until the NOCOLLECT option is specified.

HPLOTS=number
sets the number of scatter plots that can be displayed across the page. The procedure begins with one plot per page. The value of the HPLOTS= option remains in effect until you change it in a later PLOT statement. See the VPLOTS= option for an example.
NOCOLLECT

specifies that the collection of scatter plots ends after adding the plots in the current PLOT statement. PROC REG starts with the NOCOLLECT option in effect. After you specify the NOCOLLECT option, any following PLOT statement produces a new plot that contains only the plots requested by that PLOT statement.

For more information, see the COLLECT option.

OVERLAY

allows requested scatter plots to be superimposed. The axes are scaled so that points on all plots are shown. If the HPLOTS= or VPLOTS= option is set to more than one, the overlaid plot occupies the first position on the page. The OVERLAY option is similar to the COLLECT option in that both options produce superimposed plots. However, OVERLAY superimposes only the plots in the associated PLOT statement; COLLECT superimposes plots across PLOT statements. The OVERLAY option can be used when the COLLECT option is in effect.

SYMBOL='character'

changes the default plotting symbol used for all scatter plots produced in the current and in subsequent PLOT statements. Both SYMBOL=’’ and SYMBOL=’ ’ are allowed.

If the SYMBOL= option has not been specified, the default symbol is ’1’ for positions with one observation, ’2’ for positions with two observations, and so on. For positions with more than 9 observations, ’*’ is used. The SYMBOL= option (or a plotting symbol) is needed to avoid any confusion caused by this default convention. Specifying a particular symbol is especially important when either the OVERLAY or COLLECT option is being used.

If you specify the SYMBOL= option and use a number for character, that number is used for all points in the plot. For example, the statement

```
plot y*x / symbol='1';
```

produces a plot with the symbol ’1’ used for all points.

If you specify a plotting symbol and the SYMBOL= option, the plotting symbol overrides the SYMBOL= option. For example, in the statements

```
plot y*x y*v='.' / symbol='*';
```

the symbol used for the plot of Y against X is ’*’, and a ’.’ is used for the plot of Y against V.

If a paint symbol is defined with a PAINT statement, the paint symbol takes precedence over both the SYMBOL= option and the default plotting symbol for the PLOT statement.
VPLOTS=number
sets the number of scatter plots that can be displayed down the page. The procedure begins with one plot per page. The value of the VPLOTS= option remains in effect until you change it in a later PLOT statement.

For example, to specify a total of six plots per page, with two rows of three plots, use the HPLOTS= and VPLOTS= options as follows:

```plaintext
plot y1*x1 y1*x2 y1*x3 y2*x1 y2*x2 y2*x3 /
    hplots=3 vplots=2;
run;
```

PRINT Statement

PRINT < options > < ANOVA > < MODELDATA > ;

The PRINT statement enables you to interactively display the results of MODEL statement options, produce an ANOVA table, display the data for variables used in the current model, or redisplay the options specified in a MODEL or a previous PRINT statement. In addition, like most other interactive statements in PROC REG, the PRINT statement implicitly refits the model; thus, effects of REWEIGHT statements are seen in the resulting tables. If the experimental ODS graphics are in effect (see the “ODS Graphics” section on page 3922), the PRINT statement also requests the display of the ODS graphics associated with the current model.

The following specifications can appear in the PRINT statement:

- **options** interactively displays the results of MODEL statement options, where *options* is one or more of the following: ACOV, ALL, CLI, CLM, COLLIN, COLLINOINT, CORRB, COVB, DW, I, INFLUENCE, P, PARTIAL, PCORR1, PCORR2, R, SCORR1, SCORR2, SEQB, SPEC, SS1, SS2, STB, TOL, VIF, or XPX. See the “MODEL Statement” section on page 3821 for a description of these options.
- **ANOVA** produces the ANOVA table associated with the current model. This is either the model specified in the last MODEL statement or the model that incorporates changes made by ADD, DELETE or REWEIGHT statements after the last MODEL statement.
- **MODELDATA** displays the data for variables used in the current model.

Use the statement

```plaintext
print;
```

to reprint options in the most recently specified PRINT or MODEL statement.

Options that require original data values, such as R or INFLUENCE, cannot be used when a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as the input data set to PROC REG. See the “Input Data Sets” section on page 3860 for more detail.
REFIT Statement

REFIT;

The REFIT statement causes the current model and corresponding statistics to be recomputed immediately. No output is generated by this statement. The REFIT statement is needed after one or more REWEIGHT statements to cause them to take effect before subsequent PAINT or REWEIGHT statements. This is sometimes necessary when you are using statistical conditions in REWEIGHT statements. For example, with these statements

paint student.>2;
plot student.*p.;
reweight student.>2;
refit;
paint student.>2;
plot student.*p.;

the second PAINT statement paints any additional observations that meet the condition after deleting observations and refitting the model. The REFIT statement is used because the REWEIGHT statement does not cause the model to be recomputed. In this particular example, the same effect could be achieved by replacing the REFIT statement with a PLOT statement.

Most interactive statements can be used to implicitly refit the model; any plots or statistics produced by these statements reflect changes made to the model and changes made to the data used to compute the model. The two exceptions are the PAINT and REWEIGHT statements, which do not cause the model to be recomputed.

RESTRICT Statement

RESTRICT  \textit{equation} < , \ldots, \textit{equation} > ;

A RESTRICT statement is used to place restrictions on the parameter estimates in the MODEL preceding it. More than one RESTRICT statement can follow each MODEL statement. Each RESTRICT statement replaces any previous RESTRICT statement. To lift all restrictions on a model, submit a new MODEL statement. If there are several restrictions, separate them with commas. The statement

\begin{verbatim}
restrict equation1=equation2=equation3;
\end{verbatim}

is equivalent to imposing the two restrictions

\begin{verbatim}
restrict equation1=equation2;
restrict equation2=equation3;
\end{verbatim}

Each restriction is written as a linear equation and can be written as

\textit{equation}
or

\[ equation = equation \]

The form of each equation is

\[ c_1 \times variable_1 \pm c_2 \times variable_2 \pm \cdots \pm c_n \times variable_n \]

where the \( c_j \)'s are constants and the \( variable_j \)'s are any regressor variables.

When no equal sign appears, the linear combination is set equal to zero. Each variable name mentioned must be a variable in the MODEL statement to which the RESTRICT statement refers. The keyword INTERCEPT can also be used as a variable name, and it refers to the intercept parameter in the regression model.

Note that the parameters associated with the variables are restricted, not the variables themselves. Restrictions should be consistent and not redundant.

Examples of valid RESTRICT statements include the following:

```
restrict x1;
restrict a+b=1;
restrict a=b=c;
restrict a=b, b=c;
restrict 2*f=g+h, intercept+f=0;
restrict f=g=h=intercept;
```

The third and fourth statements in this list produce identical restrictions. You cannot specify

```
restrict f-g=0,
   f-intercept=0,
   g-intercept=1;
```

because the three restrictions are not consistent. If these restrictions are included in a RESTRICT statement, one of the restrict parameters is set to zero and has zero degrees of freedom, indicating that PROC REG is unable to apply a restriction.

The restrictions usually operate even if the model is not of full rank. Check to ensure that \( DF = 1 \) for each restriction. In addition, the Model DF should decrease by 1 for each restriction.

The parameter estimates are those that minimize the quadratic criterion (SSE) subject to the restrictions. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as zero.

The method used for restricting the parameter estimates is to introduce a Lagrangian parameter for each restriction (Pringle and Raynor 1971). The estimates of these parameters are displayed with test statistics. Note that the \( t \) statistic reported for
the Lagrangian parameters does not follow a Student’s $t$ distribution, but its square follows a beta distribution (LaMotte 1994). The $p$-value for these parameters is computed using the beta distribution.

The Lagrangian parameter $\gamma$ measures the sensitivity of the SSE to the restriction constant. If the restriction constant is changed by a small amount $\epsilon$, the SSE is changed by $2\gamma\epsilon$. The $t$ ratio tests the significance of the restrictions. If $\gamma$ is zero, the restricted estimates are the same as the unrestricted estimates, and a change in the restriction constant in either direction increases the SSE.

RESTRICT statements are ignored if the PCOMIT= or RIDGE= option is specified in the PROC REG statement.

### REWEIGHT Statement

```
REWEIGHT < condition | ALLOBS > < / options > ;
REWEIGHT < STATUS | UNDO > ;
```

The REWEIGHT statement interactively changes the weights of observations that are used in computing the regression equation. The REWEIGHT statement can change observation weights, or set them to zero, which causes selected observations to be excluded from the analysis. When a REWEIGHT statement sets observation weights to zero, the observations are not deleted from the data set. More than one REWEIGHT statement can be used. The requests from all REWEIGHT statements are applied to the subsequent statements. Each use of the REWEIGHT statement modifies the MODEL label.

The model and corresponding statistics are not recomputed after a REWEIGHT statement. For example, with the following statements

```
reweight r.>0;
reweight r.>0;
```

the second REWEIGHT statement does not exclude any additional observations since the model is not recomputed after the first REWEIGHT statement. Use either a REFIT statement to explicitly refit the model, or implicitly refit the model by following the REWEIGHT statement with any other interactive statement except a PAINT statement or another REWEIGHT statement.

The REWEIGHT statement cannot be used if a TYPE=CORR, TYPE=COV, or TYPE=SSCP data set is used as an input data set to PROC REG. Note that the syntax used in the REWEIGHT statement is the same as the syntax in the PAINT statement.

The syntax of the REWEIGHT statement is described in the following sections. For detailed examples of using this statement see the section “Reweighting Observations in an Analysis” on page 3903.
Specifying Condition

Condition is used to find observations to be reweighted. The syntax of condition is

\[
\text{variable compare value}
\]

or

\[
\text{variable compare value logical variable compare value}
\]

where

variable is one of the following:

- a variable name in the input data set
- OBS, which is the observation number
- keyword., where keyword is a keyword for a statistic requested in the OUTPUT statement. The keyword specification is applied to all dependent variables in the model.

compare is an operator that compares variable to value. Compare can be any one of the following: <, <=, >, >=, =, ^=. The operators LT, LE, GT, GE, EQ, and NE can be used instead of the preceding symbols. Refer to the “Expressions” chapter in SAS Language Reference: Concepts for more information on comparison operators.

value gives an unformatted value of variable. Observations are selected to be reweighted if they satisfy the condition created by variable compare value. Value can be a number or a character string. If value is a character string, it must be eight characters or less and must be enclosed in quotes. In addition, value is case-sensitive. In other words, the following two statements are not the same:

\[
\text{reweight name='steve';}
\]

\[
\text{reweight name='Steve';}
\]

logical is one of two logical operators. Either AND or OR can be used. To specify AND, use AND or the symbol &. To specify OR, use OR or the symbol |.

Examples of the variable compare value form are

\[
\begin{align*}
\text{reweight obs.} & \leq 10; \\
\text{reweight temp} & = 55; \\
\text{reweight type} & = 'new';
\end{align*}
\]

Examples of the variable compare value logical variable compare value form are

\[
\begin{align*}
\text{reweight obs.} & \leq 10 \text{ and residual.<2;}
\text{reweight student} & < -2 \text{ or student.}>2; \\
\text{reweight name='Mary' \mid name='Susan';}
\end{align*}
\]
Using ALLOBS

Instead of specifying condition, you can use the ALLOBS option to select all observations. This is most useful when you want to restore the original weights of all observations. For example,

```
reweight allobs / reset;
```

resets weights for all observations and uses all observations in the subsequent analysis. Note that

```
reweight allobs;
```

specifies that all observations be excluded from analysis. Consequently, using ALLOBS is useful only if you also use one of the options discussed in the following section.

Options in the REWEIGHT Statement

The following options can be used when either a condition, ALLOBS, or nothing is specified before the slash. If only an option is listed, the option applies to the observations selected in the previous REWEIGHT statement, not to the observations selected by reapplying the condition from the previous REWEIGHT statement. For example, with the statements

```
reweight r.>0 / weight=0.1;
refit;
reweight;
```

the second REWEIGHT statement excludes from the analysis only those observations selected in the first REWEIGHT statement. No additional observations are excluded even if there are new observations that meet the condition in the first REWEIGHT statement.

Note: Options are not available when either the UNDO or STATUS option is used.

**NOLIST**

suppresses the display of the selected observation numbers. If you omit the NOLIST option, a list of observations selected is written to the log.

**RESET**

resets the observation weights to their original values as defined by the WEIGHT statement or to WEIGHT=1 if no WEIGHT statement is specified. For example,

```
reweight / reset;
```

resets observation weights to the original weights in the data set. If previous REWEIGHT statements have been submitted, this REWEIGHT statement applies
only to the observations selected by the previous REWEIGHT statement. Note that, although the RESET option does reset observation weights to their original values, it does not cause the model and corresponding statistics to be recomputed.

**WEIGHT=** *value*
changes observation weights to the specified nonnegative real number. If you omit the WEIGHT= option, the observation weights are set to zero, and observations are excluded from the analysis. For example,

```plaintext
    reweight name='Alan';
    ...other interactive statements
    reweight / weight=0.5;
```

The first REWEIGHT statement changes weights to zero for all observations with `name='Alan'`, effectively deleting these observations. The subsequent analysis does not include these observations. The second REWEIGHT statement applies only to those observations selected by the previous REWEIGHT statement, and it changes the weights to 0.5 for all the observations with NAME='Alan'. Thus, the next analysis includes all original observations; however, those observations with NAME='Alan' have their weights set to 0.5.

**STATUS and UNDO**

If you omit `condition` and the ALLOBS options, you can specify one of the following options.

**STATUS**
writes to the log the observation’s number and the weight of all reweighted observations. If an observation’s weight has been set to zero, it is reported as deleted. However, the observation is not deleted from the data set, only from the analysis.

**UNDO**
undoes the changes made by the most recent REWEIGHT statement. Weights may be, but are not necessarily, reset. For example, in these statements

```plaintext
    reweight student.>2 / weight=0.1;
    reweight;
    reweight undo;
```

the first REWEIGHT statement sets the weights of observations that satisfy the condition to 0.1. The second REWEIGHT statement sets the weights of the same observations to zero. The third REWEIGHT statement undoes the second, changing the weights back to 0.1.
The TEST statement tests hypotheses about the parameters estimated in the preceding MODEL statement. It has the same syntax as the RESTRICT statement except that it allows an option. Each equation specifies a linear hypothesis to be tested. The rows of the hypothesis are separated by commas.

Variable names must correspond to regressors, and each variable name represents the coefficient of the corresponding variable in the model. An optional label is useful to identify each test with a name. The keyword INTERCEPT can be used instead of a variable name to refer to the model’s intercept.

The REG procedure performs an $F$ test for the joint hypotheses specified in a single TEST statement. More than one TEST statement can accompany a MODEL statement. The numerator is the usual quadratic form of the estimates; the denominator is the mean squared error. If hypotheses can be represented by

$$L\beta = c$$

then the numerator of the $F$ test is

$$Q = (Lb - c)'(L(X'X)^{-1}L')^{-1}(Lb - c)$$

divided by degrees of freedom, where $b$ is the estimate of $\beta$. For example,

```plaintext
model y=a1 a2 b1 b2;
aplus: test a1+a2=1;
b1: test b1=0, b2=0;
b2: test b1, b2;
```

The last two statements are equivalent; since no constant is specified, zero is assumed.

Note that, when the ACOV option is specified in the MODEL statement, tests are recomputed using the heteroscedasticity consistent covariance matrix (see the section “Testing for Heteroscedasticity” on page 3910).

One option can be specified in the TEST statement after a slash (/):

**PRINT**

displays intermediate calculations. This includes $L(X'X)^{-1}L'$ bordered by $Lb - c$, and $(L(X'X)^{-1}L')^{-1}$ bordered by $(L(X'X)^{-1}L')^{-1}(Lb - c)$. 
VAR Statement

VAR variables;

The VAR statement is used to include numeric variables in the crossproducts matrix that are not specified in the first MODEL statement.

Variables not listed in MODEL statements before the first RUN statement must be listed in the VAR statement if you want the ability to add them interactively to the model with an ADD statement, to include them in a new MODEL statement, or to plot them in a scatter plot with the PLOT statement.

In addition, if you want to use options in the PROC REG statement and do not want to fit a model to the data (with a MODEL statement), you must use a VAR statement.

WEIGHT Statement

WEIGHT variable;

A WEIGHT statement names a variable in the input data set with values that are relative weights for a weighted least-squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, then the weighted estimates are the best linear unbiased estimates (BLUE).

Values of the weight variable must be nonnegative. If an observation’s weight is zero, the observation is deleted from the analysis. If a weight is negative or missing, it is set to zero, and the observation is excluded from the analysis. A more complete description of the WEIGHT statement can be found in Chapter 32, “The GLM Procedure.”

Observation weights can be changed interactively with the REWEIGHT statement; see the section “REWEIGHT Statement” beginning on page 3854.

Details

Missing Values

PROC REG constructs only one crossproducts matrix for the variables in all regressions. If any variable needed for any regression is missing, the observation is excluded from all estimates. If you include variables with missing values in the VAR statement, the corresponding observations are excluded from all analyses, even if you never include the variables in a model. PROC REG assumes that you may want to include these variables after the first RUN statement and deletes observations with missing values.
PROC REG does not compute new regressors. For example, if you want a quadratic term in your model, you should create a new variable when you prepare the input data. For example, the statement

```plaintext
model y=x1 x1*x1;
```

is not valid. Note that this MODEL statement is valid in the GLM procedure.

The input data set for most applications of PROC REG contains standard rectangular data, but special TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets can also be used. TYPE=CORR and TYPE=COV data sets created by the CORR procedure contain means and standard deviations. In addition, TYPE=CORR data sets contain correlations and TYPE=COV data sets contain covariances. TYPE=SSCP data sets created in previous runs of PROC REG that used the OUTSSCP= option contain the sums of squares and crossproducts of the variables. See Appendix A, “Special SAS Data Sets,” and the “SAS Files” section in SAS Language Reference: Concepts for more information on special SAS data sets.

These summary files save CPU time. It takes $nk^2$ operations (where $n =$ number of observations and $k =$ number of variables) to calculate crossproducts; the regressions are of the order $k^3$. When $n$ is in the thousands and $k$ is less than 10, you can save 99 percent of the CPU time by reusing the SSCP matrix rather than recomputing it.

When you want to use a special SAS data set as input, PROC REG must determine the TYPE for the data set. PROC CORR and PROC REG automatically set the type for their output data sets. However, if you create the data set by some other means (such as a DATA step) you must specify its type with the TYPE= data set option. If the TYPE for the data set is not specified when the data set is created, you can specify TYPE= as a data set option in the DATA= option in the PROC REG statement. For example,

```plaintext
proc reg data=a(type=corr);
```

When TYPE=CORR, TYPE=COV, or TYPE=SSCP data sets are used with PROC REG, statements and options that require the original data values have no effect. The OUTPUT, PAINT, PLOT, and REWEIGHT statements and the MODEL and PRINT statement options P, R, CLM, CLI, DW, INFLUENCE, and PARTIAL are disabled since the original observations needed to calculate predicted and residual values are not present.

**Example Using TYPE=CORR Data Set**

This example uses PROC CORR to produce an input data set for PROC REG. The fitness data for this analysis can be found in Example 61.1 on page 3924.

```plaintext
proc corr data=fitness outp=r noprint;
    var Oxygen RunTime Age Weight RunPulse MaxPulse RestPulse;
```
Input Data Sets

Proc print data=r;
proc reg data=r;
  model Oxygen=RunTime Age Weight;
run;

Since the OUTP= data set from PROC CORR is automatically set to TYPE=CORR, the TYPE= data set option is not required in this example. The data set containing the correlation matrix is displayed by the PRINT procedure as shown in Figure 61.12. Figure 61.13 shows results from the regression using the TYPE=CORR data as an input data set.

Figure 61.13. Regression on TYPE=CORR Data Set
Example Using TYPE=SSCP Data Set

The following example uses the saved crossproducts matrix:

```latex
proc reg data=fitness outsscp=sscp noprint;
   model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse;
proc print data=sscp;
proc reg data=sscp;
   model Oxygen=RunTime Age Weight;
run;
```

First, all variables are used to fit the data and create the SSCP data set. Figure 61.14 shows the PROC PRINT display of the SSCP data set. The SSCP data set is then used as the input data set for PROC REG, and a reduced model is fit to the data. Figure 61.15 also shows the PROC REG results for the reduced model. (For the PROC REG results for the full model, see Figure 61.27 on page 3877.)

In the preceding example, the TYPE= data set option is not required since PROC REG sets the OUTSSCP= data set to TYPE=SSCP.

```latex
Obs _TYPE_ _NAME_ Intercept RunTime Age Weight RunPulse MaxPulse RestPulse Oxygen

---

### Output Data Sets

#### OUTEST= Data Set

The OUTEST= specification produces a TYPE=EST output SAS data set containing estimates and optional statistics from the regression models. For each BY group on each dependent variable occurring in each MODEL statement, PROC REG outputs an observation to the OUTEST= data set. The variables output to the data set are as follows:

- the BY variables, if any
- `_MODEL_`, a character variable containing the label of the corresponding MODEL statement, or `MODELn` if no label is specified, where `n` is 1 for the first MODEL statement, 2 for the second model statement, and so on
- `_TYPE_`, a character variable with the value 'PARMS' for every observation
- `_DEPVAR_`, the name of the dependent variable
- `_RMSE_`, the root mean squared error or the estimate of the standard deviation of the error term
- `Intercept`, the estimated intercept, unless the NOINT option is specified
- all the variables listed in any MODEL or VAR statement. Values of these variables are the estimated regression coefficients for the model. A variable
that does not appear in the model corresponding to a given observation has a missing value in that observation. The dependent variable in each model is given a value of -1.

If you specify the COVOUT option, the covariance matrix of the estimates is output after the estimates; the _TYPE_ variable is set to the value ‘COV’ and the names of the rows are identified by the 8-byte character variable, _NAME_.

If you specify the TABLEOUT option, the following statistics listed by _TYPE_ are added after the estimates:

- STDERR, the standard error of the estimate
- T, the t statistic for testing if the estimate is zero
- PVALUE, the associated p-value
- L\text{n}B, the 100(1 - \alpha) lower confidence for the estimate, where n is the nearest integer to 100(1 - \alpha) and \alpha defaults to 0.05 or is set using the ALPHA= option in the PROC REG or MODEL statement
- U\text{n}B, the 100(1 - \alpha) upper confidence for the estimate

Specifying the option ADJRSQ, AIC, BIC, CP, EDF, GMSEP, JP, MSE, PC, R\text{SQUARE}, SBC, SP, or SSE in the PROC REG or MODEL statement automatically outputs these statistics and the model $R^2$ for each model selected, regardless of the model selection method. Additional variables, in order of occurrence, are as follows.

- _IN_, the number of regressors in the model not including the intercept
- _P_, the number of parameters in the model including the intercept, if any
- _EDF_, the error degrees of freedom
- _SSE_, the error sum of squares, if the SSE option is specified
- _MSE_, the mean squared error, if the MSE option is specified
- _RSQ_, the $R^2$ statistic
- _ADJRSQ_, the adjusted $R^2$, if the ADJRSQ option is specified
- _CP_, the $C_p$ statistic, if the CP option is specified
- _SP_, the $S_p$ statistic, if the SP option is specified
- _JP_, the $J_p$ statistic, if the JP option is specified
- _PC_, the PC statistic, if the PC option is specified
- _GMSEP_, the GMSEP statistic, if the GMSEP option is specified
- _AIC_, the AIC statistic, if the AIC option is specified
- _BIC_, the BIC statistic, if the BIC option is specified
- _SBC_, the SBC statistic, if the SBC option is specified
The following is an example with a display of the OUTEST= data set. This example uses the population data given in the section “Polynomial Regression” beginning on page 3804. Figure 61.16 on page 3865 through Figure 61.18 on page 3866 show the regression equations and the resulting OUTEST= data set.

```
proc reg data=USPopulation outest=est;
  m1: model Population=Year;
  m2: model Population=Year YearSq;
proc print data=est;
run;
```

Figure 61.18. OUTEST= Data Set

The following modification of the previous example uses the TABLEOUT and ALPHA= options to obtain additional information in the OUTEST= data set:

```
proc reg data=USPopulation outest=est tableout alpha=0.1;
  m1: model Population=Year/noprint;
  m2: model Population=Year YearSq/noprint;
proc print data=est;
run;
```

Notice that the TABLEOUT option causes standard errors, t statistics, p-values, and confidence limits for the estimates to be added to the OUTEST= data set. Also note that the ALPHA= option is used to set the confidence level at 90%. The OUTEST= data set follows.

Figure 61.19. The OUTEST= Data Set When TABLEOUT is Specified

A slightly different OUTEST= data set is created when you use the RSQUARE selection method. This example requests only the “best” model for each subset size but asks for a variety of model selection statistics, as well as the estimated regression coefficients. An OUTEST= data set is created and displayed. See Figure 61.20 and Figure 61.21 for results.

```r
proc reg data=fitness outest=est;
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse /
   selection=rsquare mse jp gmsep cp aic bic sbc b best=1;
   proc print data=est;
run;

Figure 61.21. PROC PRINT Output for Physical Fitness Data: OUTTEST= Data Set

OUTSSCP= Data Sets

The OUTSSCP= option produces a TYPE=SSCP output SAS data set containing sums of squares and crossproducts. A special row (observation) and column (variable) of the matrix called Intercept contain the number of observations and sums.
Observations are identified by the character variable _NAME_. The data set contains all variables used in MODEL statements. You can specify additional variables that you want included in the crossproducts matrix with a VAR statement.

The SSCP data set is used when a large number of observations are explored in many different runs. The SSCP data set can be saved and used for subsequent runs, which are much less expensive since PROC REG never reads the original data again. If you run PROC REG once to create only a SSCP data set, you should list all the variables that you may need in a VAR statement or include all the variables that you may need in a MODEL statement.

The following example uses the fitness data from Example 61.1 on page 3924 to produce an output data set with the OUTSSCP= option. The resulting output is shown in Figure 61.22.

```sas
proc reg data=fitness outsscp=sscp;
  var Oxygen RunTime Age Weight RestPulse RunPulse MaxPulse;
  proc print data=sscp;
  run;
```

Since a model is not fit to the data and since the only request is to create the SSCP data set, a MODEL statement is not required in this example. However, since the MODEL statement is not used, the VAR statement is required.

Figure 61.22. SSCP Data Set Created with OUTSSCP= Option: REG Procedure

Interactive Analysis

PROC REG enables you to change interactively both the model and the data used to compute the model, and to produce and highlight scatter plots. See the section “Using PROC REG Interactively” on page 3812 for an overview of interactive analysis using PROC REG. The following statements can be used interactively (without reinvoking PROC REG): ADD, DELETE, MODEL, MTEST, OUTPUT, PAINT, PLOT, PRINT, REFIT, RESTRICT, REWEIGHT, and TEST. All interactive features are disabled if there is a BY statement.

The ADD, DELETE and REWEIGHT statements can be used to modify the current MODEL. Every use of an ADD, DELETE or REWEIGHT statement causes the model label to be modified by attaching an additional number to it. This number
is the cumulative total of the number of ADD, DELETE or REWEIGHT statements following the current MODEL statement.

A more detailed explanation of changing the data used to compute the model is given in the section “Reweighting Observations in an Analysis” on page 3903. Extra features for line printer scatter plots are discussed in the section “Line Printer Scatter Plot Features” on page 3882.

The following example illustrates the usefulness of the interactive features. First, the full regression model is fit to the class data (see the “Getting Started” section on page 3800), and Figure 61.23 is produced.

```
proc reg data=Class;
  model Weight=Age Height;
run;
```

![Figure 61.23. Interactive Analysis: Full Model](image-url)
Next, the regression model is reduced by the following statements, and Figure 61.24
is produced.

\begin{verbatim}
delete age;
print;
run;
\end{verbatim}

\begin{verbatim}

\end{verbatim}

\textbf{Figure 61.24.} Interactive Analysis: Reduced Model

Note that the MODEL label has been changed from MODEL1 to MODEL1.1, as the
original MODEL has been changed by the delete statement.

The following statements generate a scatter plot of the residuals against the predicted
values from the full model. Figure 61.25 is produced, and the scatter plot shows a
possible outlier.

\begin{verbatim}
add age;
plot r.*p. / cframe=ligr;
run;
\end{verbatim}
Figure 61.25. Interactive Analysis: Scatter Plot

The following statements delete the observation with the largest residual, refit the regression model, and produce a scatter plot of residuals against predicted values for the refitted model. Figure 61.26 shows the new scatter plot.

```plaintext
reweight r.>20;
plot / cframe=ligr;
run;
```
Model-Selection Methods

The nine methods of model selection implemented in PROC REG are specified with the SELECTION= option in the MODEL statement. Each method is discussed in this section.

**Full Model Fitted (NONE)**

This method is the default and provides no model selection capability. The complete model specified in the MODEL statement is used to fit the model. For many regression analyses, this may be the only method you need.

**Forward Selection (FORWARD)**

The forward-selection technique begins with no variables in the model. For each of the independent variables, the FORWARD method calculates $F$ statistics that reflect the variable’s contribution to the model if it is included. The $p$-values for these $F$ statistics are compared to the SLENTRY= value that is specified in the MODEL statement (or to 0.50 if the SLENTRY= option is omitted). If no $F$ statistic has a significance level greater than the SLENTRY= value, the FORWARD selection stops. Otherwise, the FORWARD method adds the variable that has the largest $F$ statistic to the model. The FORWARD method then calculates $F$ statistics again for the variables still remaining outside the model, and the evaluation process is repeated. Thus, variables are added one by one to the model until no remaining variable produces a significant $F$ statistic. Once a variable is in the model, it stays.

![Figure 61.26. Interactive Analysis: Scatter Plot for Refitted Model](image-url)
**Backward Elimination (BACKWARD)**

The backward elimination technique begins by calculating $F$ statistics for a model, including all of the independent variables. Then the variables are deleted from the model one by one until all the variables remaining in the model produce $F$ statistics significant at the SLSTAY= level specified in the MODEL statement (or at the 0.10 level if the SLSTAY= option is omitted). At each step, the variable showing the smallest contribution to the model is deleted.

**Stepwise (STEPWISE)**

The stepwise method is a modification of the forward-selection technique and differs in that variables already in the model do not necessarily stay there. As in the forward-selection method, variables are added one by one to the model, and the $F$ statistic for a variable to be added must be significant at the SLENTRY= level. After a variable is added, however, the stepwise method looks at all the variables already included in the model and deletes any variable that does not produce an $F$ statistic significant at the SLSTAY= level. Only after this check is made and the necessary deletions accomplished can another variable be added to the model. The stepwise process ends when none of the variables outside the model has an $F$ statistic significant at the SENTRY= level and every variable in the model is significant at the SLSTAY= level, or when the variable to be added to the model is the one just deleted from it.

**Maximum $R^2$ Improvement (MAXR)**

The maximum $R^2$ improvement technique does not settle on a single model. Instead, it tries to find the “best” one-variable model, the “best” two-variable model, and so forth, although it is not guaranteed to find the model with the largest $R^2$ for each size.

The MAXR method begins by finding the one-variable model producing the highest $R^2$. Then another variable, the one that yields the greatest increase in $R^2$, is added. Once the two-variable model is obtained, each of the variables in the model is compared to each variable not in the model. For each comparison, the MAXR method determines if removing one variable and replacing it with the other variable increases $R^2$. After comparing all possible switches, the MAXR method makes the switch that produces the largest increase in $R^2$. Comparisons begin again, and the process continues until the MAXR method finds that no switch could increase $R^2$. Thus, the two-variable model achieved is considered the “best” two-variable model the technique can find. Another variable is then added to the model, and the comparing-and-switching process is repeated to find the “best” three-variable model, and so forth.

The difference between the STEPWISE method and the MAXR method is that all switches are evaluated before any switch is made in the MAXR method. In the STEPWISE method, the “worst” variable may be removed without considering what adding the “best” remaining variable might accomplish. The MAXR method may require much more computer time than the STEPWISE method.
Minimum $R^2$ (MINR) Improvement

The MINR method closely resembles the MAXR method, but the switch chosen is the one that produces the smallest increase in $R^2$. For a given number of variables in the model, the MAXR and MINR methods usually produce the same “best” model, but the MINR method considers more models of each size.

$R^2$ Selection (RSQUARE)

The RSQUARE method finds subsets of independent variables that best predict a dependent variable by linear regression in the given sample. You can specify the largest and smallest number of independent variables to appear in a subset and the number of subsets of each size to be selected. The RSQUARE method can efficiently perform all possible subset regressions and display the models in decreasing order of $R^2$ magnitude within each subset size. Other statistics are available for comparing subsets of different sizes. These statistics, as well as estimated regression coefficients, can be displayed or output to a SAS data set.

The subset models selected by the RSQUARE method are optimal in terms of $R^2$ for the given sample, but they are not necessarily optimal for the population from which the sample is drawn or for any other sample for which you may want to make predictions. If a subset model is selected on the basis of a large $R^2$ value or any other criterion commonly used for model selection, then all regression statistics computed for that model under the assumption that the model is given a priori, including all statistics computed by PROC REG, are biased.

While the RSQUARE method is a useful tool for exploratory model building, no statistical method can be relied on to identify the “true” model. Effective model building requires substantive theory to suggest relevant predictors and plausible functional forms for the model.

The RSQUARE method differs from the other selection methods in that RSQUARE always identifies the model with the largest $R^2$ for each number of variables considered. The other selection methods are not guaranteed to find the model with the largest $R^2$. The RSQUARE method requires much more computer time than the other selection methods, so a different selection method such as the STEPWISE method is a good choice when there are many independent variables to consider.

Adjusted $R^2$ Selection (ADJRSQ)

This method is similar to the RSQUARE method, except that the adjusted $R^2$ statistic is used as the criterion for selecting models, and the method finds the models with the highest adjusted $R^2$ within the range of sizes.

Mallows’ $C_p$ Selection (CP)

This method is similar to the ADJRSQ method, except that Mallows’ $C_p$ statistic is used as the criterion for model selection. Models are listed in ascending order of $C_p$. 
Additional Information on Model-Selection Methods

If the RSQUARE or STEPWISE procedure (as documented in SAS User’s Guide: Statistics, Version 5 Edition) is requested, PROC REG with the appropriate model-selection method is actually used.

Reviews of model-selection methods by Hocking (1976) and Judge et al. (1980) describe these and other variable-selection methods.

Criteria Used in Model-Selection Methods

When many significance tests are performed, each at a level of, for example, 5 percent, the overall probability of rejecting at least one true null hypothesis is much larger than 5 percent. If you want to guard against including any variables that do not contribute to the predictive power of the model in the population, you should specify a very small SLE= significance level for the FORWARD and STEPWISE methods and a very small SLS= significance level for the BACKWARD and STEPWISE methods.

In most applications, many of the variables considered have some predictive power, however small. If you want to choose the model that provides the best prediction using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size, so you should use a moderate significance level, perhaps in the range of 10 percent to 25 percent.

In addition to $R^2$, the $C_p$ statistic is displayed for each model generated in the model-selection methods. The $C_p$ statistic is proposed by Mallows (1973) as a criterion for selecting a model. It is a measure of total squared error defined as

$$C_p = \frac{SSE_p}{s^2} - (N - 2p)$$

where $s^2$ is the MSE for the full model, and $SSE_p$ is the sum-of-squares error for a model with $p$ parameters including the intercept, if any. If $C_p$ is plotted against $p$, Mallows recommends the model where $C_p$ first approaches $p$. When the right model is chosen, the parameter estimates are unbiased, and this is reflected in $C_p$ near $p$. For further discussion, refer to Daniel and Wood (1980).

The Adjusted $R^2$ statistic is an alternative to $R^2$ that is adjusted for the number of parameters in the model. The adjusted $R^2$ statistic is calculated as

$$ADJRSQ = 1 - \frac{(n - i)(1 - R^2)}{n - p}$$

where $n$ is the number of observations used in fitting the model, and $i$ is an indicator variable that is 1 if the model includes an intercept, and 0 otherwise.
Limitations in Model-Selection Methods

The use of model-selection methods can be time-consuming in some cases because there is no built-in limit on the number of independent variables, and the calculations for a large number of independent variables can be lengthy. The recommended limit on the number of independent variables for the MINR method is $20 + i$, where $i$ is the value of the INCLUDE= option.

For the RSQUARE, ADJRSQ, or CP methods, with a large value of the BEST= option, adding one more variable to the list from which regressors are selected may significantly increase the CPU time. Also, the time required for the analysis is highly dependent on the data and on the values of the BEST=, START=, and STOP= options.

Parameter Estimates and Associated Statistics

The following example uses the fitness data from Example 61.1 on page 3924. Figure 61.28 shows the parameter estimates and the tables from the SS1, SS2, STB, CLB, COVB, and CORRB options:

```sas
proc reg data=fitness;
  model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse / ss1 ss2 stb clb covb corrb;
run;
```

The procedure first displays an Analysis of Variance table (Figure 61.27). The $F$ statistic for the overall model is significant, indicating that the model explains a significant portion of the variation in the data.

![Analysis of Variance Table](image)

**Figure 61.27.** ANOVA Table

The procedure next displays Parameter Estimates and some associated statistics (Figure 61.28). First, the estimates are shown, followed by their Standard Errors. The next two columns of the table contain the $t$ statistics and the corresponding probabilities for testing the null hypothesis that the parameter is not significantly different from zero.
from zero. These probabilities are usually referred to as p-values. For example, the Intercept term in the model is estimated to be 102.9 and is significantly different from zero. The next two columns of the table are the result of requesting the SS1 and SS2 options, and they show sequential and partial Sums of Squares (SS) associated with each variable. The Standardized Estimates (produced by the STB option) are the parameter estimates that result when all variables are standardized to a mean of 0 and a variance of 1. These estimates are computed by multiplying the original estimates by the standard deviation of the regressor (independent) variable and then dividing by the standard deviation of the dependent variable. The CLB option adds the upper and lower 95% confidence limits for the parameter estimates; the $\alpha$ level can be changed by specifying the ALPHA= option in the PROC REG or MODEL statement.

```
Figure 61.28. SS1, SS2, STB, CLB, COVB, and CORRB Options: Parameter Estimates
```

The final two tables are produced as a result of requesting the COVB and CORRB options (Figure 61.29). These tables show the estimated covariance matrix of the parameter estimates, and the estimated correlation matrix of the estimates.

Figure 61.29. SS1, SS2, STB, CLB, COVB, and CORRB Options: Covariances and Correlations  

For further discussion of the parameters and statistics, see the “Displayed Output” section on page 3918, and Chapter 2, “Introduction to Regression Procedures.”

Predicted and Residual Values  

The display of the predicted values and residuals is controlled by the P, R, CLM, and CLI options in the MODEL statement. The P option causes PROC REG to display the observation number, the ID value (if an ID statement is used), the actual value, the predicted value, and the residual. The R, CLI, and CLM options also produce the items under the P option. Thus, P is unnecessary if you use one of the other options.

The R option requests more detail, especially about the residuals. The standard errors of the mean predicted value and the residual are displayed. The studentized residual, which is the residual divided by its standard error, is both displayed and plotted. A measure of influence, Cook’s $D$, is displayed. Cook’s $D$ measures the change to the estimates that results from deleting each observation (Cook 1977, 1979). This statistic is very similar to DFFITS.

The CLM option requests that PROC REG display the $100(1 - \alpha)$% lower and upper confidence limits for the mean predicted values. This accounts for the variation due to estimating the parameters only. If you want a $100(1 - \alpha)$% confidence interval for observed values, then you can use the CLI option, which adds in the variability of the error term. The $\alpha$ level can be specified with the ALPHA= option in the PROC REG or MODEL statement.

You can use these statistics in PLOT and PAINT statements. This is useful in performing a variety of regression diagnostics. For definitions of the statistics produced
by these options, see Chapter 2, "Introduction to Regression Procedures."

The following example uses the US population data found on the section "Polynomial Regression" beginning on page 3804.

```sas
data USPop2;
  input Year @@;
  YearSq=Year*Year;
datalines;
2010 2020 2030
;
data USPop2;
  set USPopulation USPop2;
proc reg data=USPop2;
  id Year;
  model Population=Year YearSq / r cli clm;
run;
```

Sum of Residuals: -4.4596E-11
Sum of Squared Residuals: 170.97193
Predicted Residual SS (PRESS): 237.71229

Figure 61.31. Regression Using the R, CLI, and CLM Options

After producing the usual Analysis of Variance and Parameter Estimates tables...
(Figure 61.30), the procedure displays the results of requesting the options for predicted and residual values (Figure 61.31). For each observation, the requested information is shown. Note that the ID variable is used to identify each observation. Also note that, for observations with missing dependent variables, the predicted value, standard error of the predicted value, and confidence intervals for the predicted value are still available.

The plot of studentized residuals and Cook’s $D$ statistics are displayed as a result of requesting the R option. In the plot of studentized residuals, a large number of observations with absolute values greater than two indicates an inadequate model. A version of the studentized residual plot can be created on a high-resolution graphics device; see Example 61.7 on page 3952 for a similar example.

**Line Printer Scatter Plot Features**

This section discusses the special options available with line printer scatter plots. Detailed examples of high resolution graphics plots and options are given in Example 61.6 on page 3950.

**Producing Scatter Plots**

The interactive PLOT statement available in PROC REG enables you to look at scatter plots of data and diagnostic statistics. These plots can help you to evaluate the model and detect outliers in your data. Several options enable you to place multiple plots on a single page, superimpose plots, and collect plots to be overlaid by later plots. The PAINT statement can be used to highlight points on a plot. See the section “Painting Scatter Plots” on page 3889 for more information on painting.

The Class data set introduced in is used in the following examples.

You can superimpose several plots with the OVERLAY option. With the following statements, a plot of Weight against Height is overlaid with plots of the predicted values and the 95% prediction intervals. The model on which the statistics are based is the full model including Height and Age. These statements produce Figure 61.32:

```sas
proc reg data=Class lineprinter;
   model Weight=Height Age / noprint;
   plot (ucl. lcl. p.)*Height='-' Weight*Height
        / overlay symbol='o';
run;
```
Figure 61.32. Scatter Plot Showing Data, Predicted Values, and Confidence Limits

In this plot, the data values are marked with the symbol ‘o’ and the predicted values and prediction interval limits are labeled with the symbol ‘-’. The plot is scaled to accommodate the points from all plots. This is an important difference from the COLLECT option, which does not rescale plots after the first plot or plots are collected. You could separate the overlaid plots by using the following statements:

```
plot;
run;
```

This places each of the four plots on a separate page, while the statements
The next example shows how you can overlay plots of statistics before and after a change in the model. For the full model involving Height and Age, the ordinary residuals and the studentized residuals are plotted against the predicted values. The COLLECT option causes these plots to be collected or retained for re-display later. The option HPLOTS=2 allows the two plots to appear side by side on one page. The symbol 'f' is used on these plots to identify them as resulting from the full model. These statements produce Figure 61.33:

```
plot r.*p. student.*p. / collect hplots=2 symbol='f';
run;
```
Figure 61.33. Collecting Residual Plots for the Full Model

Note that these plots are not overlaid. The COLLECT option does not overlay the plots in one PLOT statement but retains them so that they can be overlaid by later plots. When the COLLECT option appears in a PLOT statement, the plots in that statement become the first plots in the collection.

Next, the model is reduced by deleting the \texttt{Age} variable. The PLOT statement requests the same plots as before but labels the points with the symbol \textquote{r} denoting the reduced model. The following statements produce Figure 61.34:

\begin{verbatim}
delete Age;
plot r.*p. student.*p. / symbol='r';
run;
\end{verbatim}
Figure 61.34. Overlaid Residual Plots for Full and Reduced Models

Notice that the COLLECT option causes the corresponding plots to be overlaid. Also notice that the DELETE statement causes the model label to be changed from MODEL1 to MODEL1.1. The points labeled 'f' are from the full model, and points labeled 'r' are from the reduced model. Positions labeled '?' contain at least one point from each model. In this example, the OVERLAY option cannot be used because all of the plots to be overlaid cannot be specified in one PLOT statement. With the COLLECT option, any changes to the model or the data used to fit the model do not affect plots collected before the changes. Collected plots are always reproduced exactly as they first appear. (Similarly, a PAINT statement does not affect plots collected before the PAINT statement is issued.)
The previous example overlays the residual plots for two different models. You may prefer to see them side by side on the same page. This can also be done with the COLLECT option by using a blank plot. Continuing from the last example, the COLLECT, HPLOTS=2, and SYMBOL='r' options are still in effect. In the following PLOT statement, the CLEAR option deletes the collected plots and allows the specified plot to begin a new collection. The plot created is the residual plot for the reduced model. These statements produce Figure 61.35:

```plaintext
plot r.*p. / clear;
run;
```

Figure 61.35. Residual Plot for Reduced Model Only
The next statements add the variable AGE to the model and place the residual plot for the full model next to the plot for the reduced model. Notice that a blank plot is created in the first plot request by placing nothing between the quotes. Since the COLLECT option is in effect, this plot is superimposed on the residual plot for the reduced model. The residual plot for the full model is created by the second request. The result is the desired side-by-side plots. The NOCOLLECT option turns off the collection process after the specified plots are added and displayed. Any PLOT statements that follow show only the newly specified plots. These statements produce Figure 61.36:

```plaintext
add Age;
plot r.*p.='' r.*p.='f' / nocollect;
run;
```

Figure 61.36.  Side-by-Side Residual Plots for the Full and Reduced Models

Frequently, when the COLLECT option is in effect, you want the current and follow-
ning PLOT statements to show only the specified plots. To do this, use both the
CLEAR and NOCOLLECT options in the current PLOT statement.

Painting Scatter Plots

Painting scatter plots is a useful interactive tool that enables you to mark points of
interest in scatter plots. Painting can be used to identify extreme points in scatter plots
or to reveal the relationship between two scatter plots. The CLASS data (from the
“Simple Linear Regression” section on page 3800) is used to illustrate some of these
applications. First, a scatter plot of the studentized residuals against the predicted
values is generated. This plot is shown in Figure 61.37.
proc reg data=Class lineprinter;
   model Weight=Age Height / noprint;
   plot student.*p.;
run;

The REG Procedure
Model: MODELL
Dependent Variable: Weight

Figure 61.37. Plotting Studentized Residuals Against Predicted Values

Then, the following statements identify the observation 'Henry' in the scatter plot and produce Figure 61.38:

    paint Name='Henry' / symbol = 'H';
    plot; run;
Figure 61.38. Painting One Observation

Next, the following statements identify observations with large absolute residuals:

```
paint student.>=2 or student.<=-2 / symbol='s';
plot;
run;
```

The log shows the observation numbers found with these conditions and gives the painting symbol and the number of observations found. Note that the previous PAINT statement is also used in the PLOT statement. Figure 61.39 shows the scatter plot produced by the preceding statements.
Figure 61.39.  Painting Several Observations

The following statements relate two different scatter plots. These statements produce Figure 61.40.

```sas
paint student.>=1 / symbol='p';
paint student.<1 and student.>-1 / symbol='s';
paint student.<=-1 / symbol='n';
plot student. * p. cookd. * h. / hplots=2;
run;
```
If the model is not full rank, there are an infinite number of least-squares solutions for the estimates. PROC REG chooses a nonzero solution for all variables that are linearly independent of previous variables and a zero solution for other variables. This solution corresponds to using a generalized inverse in the normal equations, and the expected values of the estimates are the Hermite normal form of $X$ multiplied by the true parameters:

$$E(b) = (X'X)^{-1}(X'X)\beta$$
Degrees of freedom for the zeroed estimates are reported as zero. The hypotheses that are not testable have \( t \) tests reported as missing. The message that the model is not full rank includes a display of the relations that exist in the matrix.

The next example uses the fitness data from Example 61.1 on page 3924. The variable \( \text{Dif} = \text{RunPulse} - \text{RestPulse} \) is created. When this variable is included in the model along with \( \text{RunPulse} \) and \( \text{RestPulse} \), there is a linear dependency (or exact collinearity) between the independent variables. Figure 61.41 shows how this problem is diagnosed.

```plaintext
data fit2;
  set fitness; Dif=RunPulse-RestPulse;
proc reg data=fit2;
    model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse Dif;
run;
```

### The REG Procedure

![Figure 61.41. Model That Is Not Full Rank: REG Procedure](image-url)
PROC REG produces a message informing you that the model is less than full rank. Parameters with DF=0 are not estimated, and parameters with DF=B are biased. In addition, the form of the linear dependency among the regressors is displayed.

**Collinearity Diagnostics**

When a regressor is nearly a linear combination of other regressors in the model, the affected estimates are unstable and have high standard errors. This problem is called **collinearity** or **multicollinearity**. It is a good idea to find out which variables are nearly collinear with which other variables. The approach in PROC REG follows that of Belsley, Kuh, and Welsch (1980). PROC REG provides several methods for detecting collinearity with the COLLIN, COLLINOINT, TOL, and VIF options.

The COLLIN option in the MODEL statement requests that a collinearity analysis be performed. First, $X'X$ is scaled to have 1s on the diagonal. If you specify the COLLINOINT option, the intercept variable is adjusted out first. Then the eigenvalues and eigenvectors are extracted. The analysis in PROC REG is reported with eigenvalues of $X'X$ rather than singular values of $X$. The eigenvalues of $X'X$ are the squares of the singular values of $X$.

The condition indices are the square roots of the ratio of the largest eigenvalue to each individual eigenvalue. The largest condition index is the condition number of the scaled $X$ matrix. Belsley, Kuh, and Welsch (1980) suggest that, when this number is around 10, weak dependencies may be starting to affect the regression estimates. When this number is larger than 100, the estimates may have a fair amount of numerical error (although the statistical standard error almost always is much greater than the numerical error).

For each variable, PROC REG produces the proportion of the variance of the estimate accounted for by each principal component. A collinearity problem occurs when a component associated with a high condition index contributes strongly (variance proportion greater than about 0.5) to the variance of two or more variables.

The VIF option in the MODEL statement provides the Variance Inflation Factors (VIF). These factors measure the inflation in the variances of the parameter estimates due to collinearities that exist among the regressor (independent) variables. There are no formal criteria for deciding if a VIF is large enough to affect the predicted values.

The TOL option requests the tolerance values for the parameter estimates. The tolerance is defined as $1/VIF$.

For a complete discussion of the preceding methods, refer to Belsley, Kuh, and Welsch (1980). For a more detailed explanation of using the methods with PROC REG, refer to Freund and Littell (1986).

This example uses the COLLIN option on the fitness data found in Example 61.1 on page 3924. The following statements produce Figure 61.42.

```plaintext
proc reg data=fitness;
    model Oxygen=RunTime Age Weight RunPulse MaxPulse RestPulse
        / tol vif collin;
run;
```

Model Fit and Diagnostic Statistics

This section gathers the formulas for the statistics available in the MODEL, PLOT, and OUTPUT statements. The model to be fit is \( Y = X\beta + \epsilon \), and the parameter estimate is denoted by \( \hat{b} = (X'X)^{-1}X'Y \). The subscript \( i \) denotes values for the \( i \)th observation, the parenthetical subscript \( (i) \) means that the statistic is computed using all observations except the \( i \)th observation, and the subscript \( jj \) indicates the \( j \)th diagonal matrix entry. The ALPHA= option in the PROC REG or MODEL statement is used to set the \( \alpha \) value for the \( t \) statistics.

Table 61.6 contains the summary statistics for assessing the fit of the model.

Influence Diagnostics

This section discusses the INFLUENCE option, which produces several influence statistics, and the PARTIAL option, which produces partial regression leverage plots.

The INFLUENCE Option

The INFLUENCE option (in the MODEL statement) requests the statistics proposed by Belsley, Kuh, and Welsch (1980) to measure the influence of each observation on the estimates. Influential observations are those that, according to various criteria, appear to have a large influence on the parameter estimates.

Let b(i) be the parameter estimates after deleting the i_th observation; let s(i)² be the variance estimate after deleting the i_th observation; let X(i) be the X matrix without the i_th observation; let ŷ(i) be the i_th value predicted without using the i_th
observation; let \( r_i = y_i - \hat{y}_i \) be the \( i \)th residual; and let \( h_i \) be the \( i \)th diagonal of the projection matrix for the predictor space, also called the hat matrix:

\[
h_i = x_i (X'X)^{-1} x_i'
\]

Belsley, Kuh, and Welsch propose a cutoff of \( 2p/n \), where \( n \) is the number of observations used to fit the model and \( p \) is the number of parameters in the model. Observations with \( h_i \) values above this cutoff should be investigated.

For each observation, PROC REG first displays the residual, the studentized residual (RSTUDENT), and the \( h_i \). The studentized residual RSTUDENT differs slightly from STUDENT since the error variance is estimated by \( s^2_{(i)} \) without the \( i \)th observation, not by \( s^2 \). For example,

\[
\text{RSTUDENT} = \frac{r_i}{s_{(i)} \sqrt{(1 - h_i)}}
\]

Observations with RSTUDENT larger than 2 in absolute value may need some attention.

The COVRATIO statistic measures the change in the determinant of the covariance matrix of the estimates by deleting the \( i \)th observation:

\[
\text{COVRATIO} = \frac{\det(s^2_{(i)}(X'_{(i)}X_{(i)})^{-1})}{\det(s^2(X'X)^{-1})}
\]

Belsley, Kuh, and Welsch suggest that observations with

\[
|\text{COVRATIO} - 1| \geq \frac{3p}{n}
\]

where \( p \) is the number of parameters in the model and \( n \) is the number of observations used to fit the model, are worth investigation.

The DFFITS statistic is a scaled measure of the change in the predicted value for the \( i \)th observation and is calculated by deleting the \( i \)th observation. A large value indicates that the observation is very influential in its neighborhood of the \( X \) space.

\[
\text{DFFITS} = \frac{\hat{y}_i - \hat{y}_{(i)}}{s_{(i)} \sqrt{h_{(i)}}}
\]

Large values of DFFITS indicate influential observations. A general cutoff to consider is 2; a size-adjusted cutoff recommended by Belsley, Kuh, and Welsch is \( 2 \sqrt{p/n} \), where \( n \) and \( p \) are as defined previously.

The DFFITS statistic is very similar to Cook’s \( D \), defined in the section “Predicted and Residual Values” on page 3879.
Chapter 61. The REG Procedure

The DFBETAS statistics are the scaled measures of the change in each parameter estimate and are calculated by deleting the $i$th observation:

$$DFBETAS_j = \frac{b_j - b_{(i)}j}{s(i)\sqrt{(X'X)_{jj}}}$$

where $(X'X)_{jj}$ is the $(j, j)$th element of $(X'X)^{-1}$.

In general, large values of DFBETAS indicate observations that are influential in estimating a given parameter. Belsley, Kuh, and Welsch recommend 2 as a general cutoff value to indicate influential observations and $2/\sqrt{n}$ as a size-adjusted cutoff.

Figure 61.43 shows the tables produced by the INFLUENCE option for the population example (the section “Polynomial Regression” beginning on page 3804). See Figure 61.30 for the fitted regression equation.

```sas
proc reg data=USPopulation;
 model Population=Year YearSq / influence;
run;

Figure 61.43. Regression Using the INFLUENCE Option

In Figure 61.43, observations 16, 17, and 19 exceed the cutoff value of 2 for RSTUDENT. None of the observations exceeds the general cutoff of 2 for DFFITS or...
the DFBETAS, but observations 16, 17, and 19 exceed at least one of the size-adjusted
cutoffs for these statistics. Observations 1 and 19 exceed the cutoff for the hat diag-
ossals, and observations 1, 2, 16, 17, and 18 exceed the cutoffs for COVRATIO. Taken
together, these statistics indicate that you should look first at observations 16, 17, and
19 and then perhaps investigate the other observations that exceeded a cutoff.

**The PARTIAL Option**

The PARTIAL option in the MODEL statement produces partial regression leverage
plots. If the experimental ODS graphics are not in effect, this option requires the use
of the LINEPRINTER option in the PROC REG statement. One plot is created for
each regressor in the current full model. For example, plots are produced for regres-
sors included by using ADD statements; plots are not produced for interim models in
the various model-selection methods but only for the full model. If you use a model-
selection method and the final model contains only a subset of the original regressors,
the PARTIAL option still produces plots for all regressors in the full model. If the
experimental ODS graphics are in effect, these plots are produced as high-resolution
graphics, in panels with a maximum of six partial regression leverage plots plots per
panel. Multiple panels are displayed for models with more than six regressors.

For a given regressor, the partial regression leverage plot is the plot of the dependent
variable and the regressor after they have been made orthogonal to the other regres-
sors in the model. These can be obtained by plotting the residuals for the dependent
variable against the residuals for the selected regressor, where the residuals for the
dependent variable are calculated with the selected regressor omitted, and the residu-
als for the selected regressor are calculated from a model where the selected regressor
is regressed on the remaining regressors. A line fit to the points has a slope equal to
the parameter estimate in the full model.

When the experimental ODS graphics are not in effect, points in the plot are marked
by the number of replicates appearing at one position. The symbol '*' is used if there
are ten or more replicates. If an ID statement is specified, the left-most nonblank
character in the value of the ID variable is used as the plotting symbol.

The following statements use the fitness data in Example 61.1 on page 3924 with the
PARTIAL option and the ODS GRAPHICS statement to produce the partial regres-
sion leverage plots. The plots are shown in Figure 61.44. For general information
about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For spe-
cific information about the graphics available in the REG procedure, see the “ODS
Graphics” section on page 3922.

```plaintext
ods html;
ods graphics on;
proc reg data=fitness;
   model Oxygen=RunTime Weight Age / partial;
run;
ods graphics off;
ods html close;
```
The following statements create a similar panel of partial regression plots using the OUTPUT dataset and the GPLOT procedure. Four plots (created by regressing Oxygen and one of the variables on the remaining variables) are displayed in Figure 61.45. Notice that the Int variable is explicitly added to be used as the intercept term.

```sas
data fitness2;
  set fitness;
  Int=1;
proc reg data=fitness2 noprint;
  model Oxygen Int = RunTime Weight Age / noint;
  output out=temp r=ry rx;
symbol1 c=blue;
proc gplot data=temp;
  plot ry*rx / cframe=ligr;
  label ry='Oxygen'
    rx='Intercept';
run;
```

**Figure 61.44.** Partial Regression Leverage Plots (Experimental)
Reweighting Observations in an Analysis

Reweighting observations is an interactive feature of PROC REG that enables you to change the weights of observations used in computing the regression equation. Observations can also be deleted from the analysis (not from the data set) by changing their weights to zero. The CLASS data (in the “Getting Started” section on page 3800) are used to illustrate some of the features of the REWEIGHT statement. First, the full model is fit, and the residuals are displayed in Figure 61.46.

```
proc reg data=Class;
   model Weight=Age Height / p;
   id Name;
run;
```

Predicted Residual SS (PRESS) 3272.72186

Figure 61.46.  Full Model for CLASS Data, Residuals Shown

Upon examining the data and residuals, you realize that observation 17 (Ronald) was mistakenly included in the analysis. Also, you would like to examine the effect of reweighting to 0.5 those observations with residuals that have absolute values greater than or equal to 17.

```
reweight obs.=17;
reweight r. le -17 or r. ge 17 / weight=0.5;
print p;
run;
```

At this point, a message (on the log) appears that tells you which observations have been reweighted and what the new weights are. Figure 61.47 is produced.

Sum of Residuals 0
Sum of Squared Residuals 1500.61194
Predicted Residual SS (PRESS) 2287.57621

NOTE: The above statistics use observation weights or frequencies.

Figure 61.47. Model with Reweighted Observations

The first REWEIGHT statement excludes observation 17, and the second REWEIGHT statement reweights observations 12 and 16 to 0.5. An important feature to note from this example is that the model is not refit until after the PRINT statement. REWEIGHT statements do not cause the model to be refit. This is so that multiple REWEIGHT statements can be applied to a subsequent model.

In this example, since the intent is to reweight observations with large residuals, the observation that was mistakenly included in the analysis should be deleted; then, the model should be fit for those remaining observations, and the observations with large residuals should be reweighted. To accomplish this, use the REFIT statement. Note that the model label has been changed from MODEL1 to MODEL1.2 as two REWEIGHT statements have been used. These statements produce Figure 61.48:

```plaintext
reweight allobs / weight=1.0;
reweight obs.=17;
refit;
reweight r. le -17 or r. ge 17 / weight=.5;
print;
run;
```
Figure 61.48. Observations Excluded from Analysis, Model Refitted and Observations Reweighted

Notice that this results in a slightly different model than the previous set of statements: only observation 16 is reweighted to 0.5. Also note that the model label is now MODEL1.5 since five REWEIGHT statements have been used for this model.

Another important feature of the REWEIGHT statement is the ability to nullify the effect of a previous or all REWEIGHT statements. First, assume that you have several REWEIGHT statements in effect and you want to restore the original weights of all the observations. The following REWEIGHT statement accomplishes this and produces Figure 61.49:

```plaintext
reweight allobs / reset;
print;
run;
```

Predicted Residual SS (PRESS) 3272.72186

Figure 61.49. Restoring Weights of All Observations

The resulting model is identical to the original model specified at the beginning of this section. Notice that the model label is now MODEL1.6. Note that the Weight column does not appear, since all observations have been reweighted to have weight=1.

Now suppose you want only to undo the changes made by the most recent REWEIGHT statement. Use REWEIGHT UNDO for this. The following statements produce Figure 61.50:

```plaintext
    reweight r. le -12 or r. ge 12 / weight=.75;
    reweight r. le -17 or r. ge 17 / weight=.5;
    reweight undo;
    print;
    run;
```

Sum of Residuals 0
Sum of Squared Residuals 1694.87114
Predicted Residual SS (PRESS) 2547.22751

NOTE: The above statistics use observation weights or frequencies.

Figure 61.50.  Example of UNDO in REWEIGHT Statement

The resulting model reflects changes made only by the first REWEIGHT statement since the third REWEIGHT statement negates the effect of the second REWEIGHT statement. Observations 1, 3, 9, 10, 12, 16, and 17 have their weights changed to 0.75. Note that the label MODEL1.9 reflects the use of nine REWEIGHT statements for the current model.

Now suppose you want to reset the observations selected by the most recent REWEIGHT statement to their original weights. Use the REWEIGHT statement with the RESET option to do this. The following statements produce Figure 61.51:

```
reweight r. le -12 or r. ge 12 / weight=.75;
reweight r. le -17 or r. ge 17 / weight=.5;
reweight / reset;
print;
run;
```

Sum of Residuals 0
Sum of Squared Residuals 1879.08980
Predicted Residual SS (PRESS) 2959.57279

NOTE: The above statistics use observation weights or frequencies.

Figure 61.51. REWEIGHT Statement with RESET option

Note that observations that meet the condition of the second REWEIGHT statement (residuals with an absolute value greater than or equal to 17) now have weights reset to their original value of 1. Observations 1, 3, 9, 10, and 17 have weights of 0.75, but observations 12 and 16 (which meet the condition of the second REWEIGHT statement) have their weights reset to 1.

Notice how the last three examples show three ways to change weights back to a previous value. In the first example, ALLOBS and the RESET option are used to change weights for all observations back to their original values. In the second example, the UNDO option is used to negate the effect of a previous REWEIGHT statement, thus changing weights for observations selected in the previous REWEIGHT statement to the weights specified in still another REWEIGHT statement. In the third example, the RESET option is used to change weights for observations selected in a previous REWEIGHT statement back to their original values. Finally, note that the label MODEL1.12 indicates that twelve REWEIGHT statements have been applied to the original model.
Testing for Heteroscedasticity

The regression model is specified as \( y_i = x_i \beta + \epsilon_i \), where the \( \epsilon_i \)’s are identically and independently distributed: \( E(\epsilon) = 0 \) and \( E(\epsilon' \epsilon) = \sigma^2 I \). If the \( \epsilon_i \)’s are not independent or their variances are not constant, the parameter estimates are unbiased, but the estimate of the covariance matrix is inconsistent. In the case of heteroscedasticity, the ACOV option provides a consistent estimate of the covariance matrix. If the regression data are from a simple random sample, the ACOV option produces the covariance matrix. This matrix is

\[
(X'X)^{-1}(X'diag(e_i^2)X)(X'X)^{-1}
\]

where

\[
e_i = y_i - x_i \hat{b}
\]

The SPEC option performs a model specification test. The null hypothesis for this test maintains that the errors are homoscedastic, independent of the regressors and that several technical assumptions about the model specification are valid. For details, see theorem 2 and assumptions 1–7 of White (1980). When the model is correctly specified and the errors are independent of the regressors, the rejection of this null hypothesis is evidence of heteroscedasticity. In implementing this test, an estimator of the average covariance matrix (White 1980, p. 822) is constructed and inverted. The nonsingularity of this matrix is one of the assumptions in the null hypothesis about the model specification. When PROC REG determines this matrix to be numerically singular, a generalized inverse is used and a note to this effect is written to the log. In such cases, care should be taken in interpreting the results of this test.

When you specify the SPEC option, tests listed in the TEST statement are performed with both the usual covariance matrix and the heteroscedasticity consistent covariance matrix. Tests performed with the consistent covariance matrix are asymptotic. For more information, refer to White (1980).

Both the ACOV and SPEC options can be specified in a MODEL or PRINT statement.

Multivariate Tests

The MTEST statement described in the “MTEST Statement” section on page 3832 can test hypotheses involving several dependent variables in the form

\[
(L\beta - c\jmath)M = 0
\]

where \( L \) is a linear function on the regressor side, \( \beta \) is a matrix of parameters, \( c \) is a column vector of constants, \( \jmath \) is a row vector of ones, and \( M \) is a linear function on the dependent side. The special case where the constants are zero is

\[
L\beta M = 0
\]
To test this hypothesis, PROC REG constructs two matrices called $H$ and $E$ that correspond to the numerator and denominator of a univariate $F$ test:

$$H = M'(LB - cj)'(L(X'X)^{-1}L' - M')^{-1}LB - cj)M$$

$$E = M'(Y'Y - B'(X'X)B)M$$

These matrices are displayed for each MTEST statement if the PRINT option is specified.

Four test statistics based on the eigenvalues of $E^{-1}H$ or $(E + H)^{-1}H$ are formed. These are Wilks’ Lambda, Pillai’s Trace, the Hotelling-Lawley Trace, and Roy’s maximum root. These test statistics are discussed in Chapter 2, “Introduction to Regression Procedures.”

The following statements perform a multivariate analysis of variance and produce Figure 61.52 through Figure 61.56:

NOTE: F Statistic for Roy’s Greatest Root is an upper bound.
NOTE: F Statistic for Wilks’ Lambda is exact.

Figure 61.56. Multivariate Analysis of Variance: Second Test (continued)

The four multivariate test statistics are all highly significant, giving strong evidence that the coefficients of drug1 and drug2 are not zero for both dependent variables.

**Autocorrelation in Time Series Data**

When regression is performed on time series data, the errors may not be independent. Often errors are autocorrelated; that is, each error is correlated with the error immediately before it. Autocorrelation is also a symptom of systematic lack of fit. The DW option provides the Durbin-Watson \( d \) statistic to test that the autocorrelation is zero:

\[
d = \frac{\sum_{i=2}^{n} (e_i - e_{i-1})^2}{\sum_{i=1}^{n} e_i^2}
\]

The value of \( d \) is close to 2 if the errors are uncorrelated. The distribution of \( d \) is reported by Durbin and Watson (1951). Tables of the distribution are found in most econometrics textbooks, such as Johnston (1972) and Pindyck and Rubinfeld (1981).

The sample autocorrelation estimate is displayed after the Durbin-Watson statistic. The sample is computed as

\[
r = \frac{\sum_{i=2}^{n} e_i e_{i-1}}{\sum_{i=1}^{n} e_i^2}
\]

This autocorrelation of the residuals may not be a very good estimate of the autocorrelation of the true errors, especially if there are few observations and the independent variables have certain patterns. If there are missing observations in the regression, these measures are computed as though the missing observations did not exist.

Positive autocorrelation of the errors generally tends to make the estimate of the error variance too small, so confidence intervals are too narrow and true null hypotheses are rejected with a higher probability than the stated significance level. Negative
autocorrelation of the errors generally tends to make the estimate of the error variance too large, so confidence intervals are too wide and the power of significance tests is reduced. With either positive or negative autocorrelation, least-squares parameter estimates are usually not as efficient as generalized least-squares parameter estimates. For more details, refer to Judge et al. (1985, Chapter 8) and the SAS/ETS User’s Guide.

The following SAS statements request the DW option for the US population data (see Figure 61.57):

```sas
proc reg data=USPopulation;
  model Population=Year YearSq / dw;
run;
```

![The REG Procedure](image)

**Figure 61.57.** Regression Using DW Option

**Computations for Ridge Regression and IPC Analysis**

In ridge regression analysis, the crossproduct matrix for the independent variables is centered (the NOINT option is ignored if it is specified) and scaled to one on the diagonal elements. The ridge constant \( k \) (specified with the RIDGE= option) is then added to each diagonal element of the crossproduct matrix. The ridge regression estimates are the least-squares estimates obtained by using the new crossproduct matrix.

Let \( X \) be an \( n \times p \) matrix of the independent variables after centering the data, and let \( Y \) be an \( n \times 1 \) vector corresponding to the dependent variable. Let \( D \) be a \( p \times p \) diagonal matrix with diagonal elements as in \( X'X \). The ridge regression estimate corresponding to the ridge constant \( k \) can be computed as

\[
D^{-\frac{1}{2}}(Z'Z' + kI_p)^{-1}Z'Y
\]

where \( Z = XD^{-\frac{1}{2}} \) and \( I_p \) is a \( p \times p \) identity matrix.

For IPC analysis, the smallest \( m \) eigenvalues of \( Z'Z \) (where \( m \) is specified with the PCOMIT= option) are omitted to form the estimates.

For information about ridge regression and IPC standardized parameter estimates, parameter estimate standard errors, and variance inflation factors, refer to Rawlings (1988), Neter, Wasserman, and Kutner (1990), and Marquardt and Snee (1975). Unlike Rawlings (1988), the REG procedure uses the mean squared errors of the submodels instead of the full model MSE to compute the standard errors of the parameter estimates.
Construction of Q-Q and P-P Plots

If a normal probability-probability or quantile-quantile plot for the variable $x$ is requested, the $n$ nonmissing values of $x$ are first ordered from smallest to largest:

$$x(1) \leq x(2) \leq \cdots \leq x(n)$$

If a Q-Q plot is requested (with a PLOT statement of the form PLOT yvariable=NQQ), the $i^{th}$ ordered value $x(i)$ is represented by a point with $y$-coordinate $x(i)$ and $x$-coordinate $\Phi^{-1}\left(\frac{i-0.375}{n+0.25}\right)$, where $\Phi(\cdot)$ is the standard normal distribution.

If a P-P plot is requested (with a PLOT statement of the form PLOT yvariable=NPP), the $i^{th}$ ordered value $x(i)$ is represented by a point with $y$-coordinate $\frac{i}{n}$ and $x$-coordinate $\Phi\left(\frac{x(i) - \mu}{\sigma}\right)$, where $\mu$ is the mean of the nonmissing $x$-values and $\sigma$ is the standard deviation. If an $x$-value has multiplicity $k$ (that is, $x(i) = \cdots = x(i+k-1)$), then only the point $\left(\Phi\left(\frac{x(i) - \mu}{\sigma}\right), \frac{i+k-1}{n}\right)$ is displayed.

Computational Methods

The REG procedure first composes a crossproducts matrix. The matrix can be calculated from input data, reformed from an input correlation matrix, or read in from an SSCP data set. For each model, the procedure selects the appropriate crossproducts from the main matrix. The normal equations formed from the crossproducts are solved using a sweep algorithm (Goodnight 1979). The method is accurate for data that are reasonably scaled and not too collinear.

The mechanism that PROC REG uses to check for singularity involves the diagonal (pivot) elements of $X'X$ as it is being swept. If a pivot is less than SINGULAR*CSS, then a singularity is declared and the pivot is not swept (where CSS is the corrected sum of squares for the regressor and SINGULAR is machine dependent but is approximately 1E-7 on most machines or reset in the PROC statement).

The sweep algorithm is also used in many places in the model-selection methods. The RSQUARE method uses the leaps and bounds algorithm by Furnival and Wilson (1974).

Computer Resources in Regression Analysis

The REG procedure is efficient for ordinary regression; however, requests for optional features can greatly increase the amount of time required.

The major computational expense in the regression analysis is the collection of the crossproducts matrix. For $p$ variables and $n$ observations, the time required is proportional to $np^2$. For each model run, PROC REG needs time roughly proportional to $k^3$, where $k$ is the number of regressors in the model. Add an additional $nk^2$ for one of the R, CLM, or CLI options and another $nk^2$ for the INFLUENCE option.
Most of the memory that PROC REG needs to solve large problems is used for crossproducts matrices. PROC REG requires $4p^2$ bytes for the main crossproducts matrix plus $4k^2$ bytes for the largest model. If several output data sets are requested, memory is also needed for buffers.

See the “Input Data Sets” section on page 3860 for information on how to use TYPE=SSCP data sets to reduce computing time.

### Displayed Output

Many of the more specialized tables are described in detail in previous sections. Most of the formulas for the statistics are in Chapter 2, “Introduction to Regression Procedures,” while other formulas can be found in the section “Model Fit and Diagnostic Statistics” on page 3896 and the “Influence Diagnostics” section on page 3898.

The analysis-of-variance table includes:

- the Source of the variation, Model for the fitted regression, Error for the residual error, and C Total for the total variation after correcting for the mean. The Uncorrected Total Variation is produced when the NOINT option is used.
- the degrees of freedom (DF) associated with the source
- the Sum of Squares for the term
- the Mean Square, the sum of squares divided by the degrees of freedom
- the F Value for testing the hypothesis that all parameters are zero except for the intercept. This is formed by dividing the mean square for Model by the mean square for Error.
- the Prob>F, the probability of getting a greater $F$ statistic than that observed if the hypothesis is true. This is the significance probability.

Other statistics displayed include the following:

- Root MSE is an estimate of the standard deviation of the error term. It is calculated as the square root of the mean square error.
- Dep Mean is the sample mean of the dependent variable.
- C.V. is the coefficient of variation, computed as 100 times Root MSE divided by Dep Mean. This expresses the variation in unitless values.
- R-Square is a measure between 0 and 1 that indicates the portion of the (corrected) total variation that is attributed to the fit rather than left to residual error. It is calculated as SS(Model) divided by SS(Total). It is also called the coefficient of determination. It is the square of the multiple correlation; in other words, the square of the correlation between the dependent variable and the predicted values.
• Adj R-Sq, the adjusted \( R^2 \), is a version of \( R^2 \) that has been adjusted for degrees of freedom. It is calculated as

\[
\bar{R}^2 = 1 - \frac{(n - i)(1 - R^2)}{n - p}
\]

where \( i \) is equal to 1 if there is an intercept and 0 otherwise; \( n \) is the number of observations used to fit the model; and \( p \) is the number of parameters in the model.

The parameter estimates and associated statistics are then displayed, and they include the following:

• the Variable used as the regressor, including the name Intercept to represent the estimate of the intercept parameter
• the degrees of freedom (DF) for the variable. There is one degree of freedom unless the model is not full rank.
• the Parameter Estimate
• the Standard Error, the estimate of the standard deviation of the parameter estimate
• \( T \) for \( H_0: \text{Parameter}=0 \), the \( t \) test that the parameter is zero. This is computed as the Parameter Estimate divided by the Standard Error.
• the Prob > |\( T \)|, the probability that a \( t \) statistic would obtain a greater absolute value than that observed given that the true parameter is zero. This is the two-tailed significance probability.

If model-selection methods other than NONE, RSQUARE, ADJRSQ, or CP are used, the analysis-of-variance table and the parameter estimates with associated statistics are produced at each step. Also displayed are

• C(p), which is Mallows’ \( C_p \) statistic
• bounds on the condition number of the correlation matrix for the variables in the model (Berk 1977)

After statistics for the final model are produced, the following is displayed when the method chosen is FORWARD, BACKWARD, or STEPWISE:

• a Summary table listing Step number, Variable Entered or Removed, Partial and Model R-Square, and C(p) and F statistics

The RSQUARE method displays its results beginning with the model containing the fewest independent variables and producing the largest \( R^2 \). Results for other models with the same number of variables are then shown in order of decreasing \( R^2 \), and so
on, for models with larger numbers of variables. The ADJRSQ and CP methods group models of all sizes together and display results beginning with the model having the optimal value of adjusted $R^2$ and $C_p$, respectively.

For each model considered, the RSQUARE, ADJRSQ, and CP methods display the following:

- Number in Model or IN, the number of independent variables used in each model
- R-Square or RSQ, the squared multiple correlation coefficient

If the B option is specified, the RSQUARE, ADJRSQ, and CP methods produce the following:

- Parameter Estimates, the estimated regression coefficients

If the B option is not specified, the RSQUARE, ADJRSQ, and CP methods display the following:

- Variables in Model, the names of the independent variables included in the model

**ODS Table Names**

PROC REG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, "Using the Output Delivery System."

**ODS Graphics (Experimental)**

This section describes the use of ODS for creating statistical graphs with the REG procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.

To request these graphs you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

When the experimental ODS graphics are in effect, the REG procedure produces a variety of plots. For models with multiple dependent variables, separate plots are produced for each dependent variable. For jobs with more than one MODEL statement, plots are produced for each model statement.

The plots available are as follows:

- With a single regressor, a scatterplot of the input data overlayed with the fitted regression line, confidence band, and prediction limits.
- A summary panel of fit diagnostics:
  - Residuals versus the predicted values
  - Studentized residuals versus the predicted values
  - Studentized residuals versus the leverage
  - Normal quantile plot of the residuals
  - Dependent variable values versus the predicted values
  - Cook’s D versus observation number
  - Histogram of the residuals
A “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals. This plot “shows how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland, 1993).

If the PLOTS(UNPACKPANELS) option is specified in the PROC REG statement, then the eight plots in the fit diagnostics panel are displayed individually.

- Panels of the residuals versus the regressors in the model. Note that each panel contains at most six plots, and multiple panels are used in the case that there are more than six regressors (including the intercept) in the model.
- If the PARTIAL option is specified in a MODEL statement, panels of the partial regression plots for each regressor (see the “The PARTIAL Option” section on page 3901). Note that each panel contains at most six partial plots, and multiple panels are used in the case that there are more than six regressors in the model.
- If the RIDGE= option is specified in the model statement, panels of ridge traces versus the specified ridge parameters for each regressor in the model. At most eight ridge traces are included on a panel and multiple panels are used for models with more than eight regressors.

**PLOTS (general-plot-options)**

specifies characteristics of the graphics produced when you use the experimental ODS GRAPHICS statement. You can specify the following *general-plot-options* in parentheses after the PLOTS option:

- **UNPACK | UNPACKPANELS** specifies that plots in the fit diagnostics panel should be displayed separately.

- **MAXPOINTS=number | NONE** specifies that plots with elements that require processing more than *number* points are suppressed. The default is MAXPOINTS=5000. This cutoff is ignored if you specify MAXPOINTS=NONE.

**ODS Graph Names**

PROC REG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 61.9.

To request these graphs you must specify the ODS GRAPHICS statement. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

### Examples

#### Example 61.1. Aerobic Fitness Prediction

Aerobic fitness (measured by the ability to consume oxygen) is fit to some simple exercise tests. The goal is to develop an equation to predict fitness based on the exercise tests rather than on expensive and cumbersome oxygen consumption measurements. Three model-selection methods are used: forward selection, backward selection, and MAXR selection. The following statements produce Output 61.1.1 through Output 61.1.5. (Collinearity diagnostics for the full model are shown in Figure 61.42 on page 3896.)
These measurements were made on men involved in a physical fitness course at N.C. State Univ. The variables are Age (years), Weight (kg), Oxygen intake rate (ml per kg body weight per minute), time to run 1.5 miles (minutes), heart rate while resting, heart rate while running (same time Oxygen rate measured), and maximum heart rate recorded while running.

***Certain values of MaxPulse were changed for this analysis.

The FORWARD model-selection method begins with no variables in the model and adds RunTime, then Age,...

Bounds on condition number: 8.7438, 137.13

The above model is the best 6-variable model found.

No further improvement in R-Square is possible.
Note that for all three of these methods, RestPulse contributes least to the model. In the case of forward selection, it is not added to the model. In the case of backward selection, it is the first variable to be removed from the model. In the case of MAXR selection, RestPulse is included only for the full model.

For the STEPWISE, BACKWARDS and FORWARD selection methods, you can control the amount of detail displayed by using the DETAILS option. For example, the following statements display only the selection summary table for the FORWARD selection method.

```sas
proc reg data=fitness;
    model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse / selection=forward details=summary;
run;
```

**Output 61.1.4.** Forward Selection Summary

Next, the RSQUARE model-selection method is used to request $R^2$ and $C_p$ statistics for all possible combinations of the six independent variables. The following statements produce **Output 61.1.5**

```sas
model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse / selection=rsquare cp;
title 'Physical fitness data: all models';
run;
```
Output 61.1.5. All Models by the RSQUARE Method: PROC REG

</table>
The models in Output 61.1.5 are arranged first by the number of variables in the model and second by the magnitude of $R^2$ for the model. Before making a final decision about which model to use, you would want to perform collinearity diagnostics. Note that, since many different models have been fit and the choice of a final model is based on $R^2$, the statistics are biased and the $p$-values for the parameter estimates are not valid.
**Example 61.2. Predicting Weight by Height and Age**

In this example, the weights of school children are modeled as a function of their heights and ages. Modeling is performed separately for boys and girls. The example shows the use of a BY statement with PROC REG, multiple MODEL statements, and the OUTEST= and OUTSSCP= options, which create data sets. Since the BY statement is used, interactive processing is not possible in this example; no statements can appear after the first RUN statement. The following statements produce Output 61.2.1 through Output 61.2.4:

```r
*-------------Data on Age, Weight, and Height of Children-------------*

The OUTEST= data set is displayed in Output 61.2.4; again, the BY groups are separated. The _MODEL_ column contains the labels for models from the model statements. If no labels are specified, the defaults MODEL1 and MODEL2 would appear as values for _MODEL_. Note that _TYPE_ = ‘PARMS’ for all observations, indicating that all observations contain parameter estimates. The _DEPVAR_ column displays the dependent variable, and the _RMSE_ column gives the Root Mean Square Error for the associated model. The Intercept column gives the estimate for the intercept for the associated model, and variables with the same name
as variables in the original data set (height, age) give parameter estimates for those variables. The dependent variable, weight, is shown with a value of −1. The _IN_ column contains the number of regressors in the model not including the intercept; _P_ contains the number of parameters in the model; _EDF_ contains the error degrees of freedom; and _RSQ_ contains the $R^2$ statistic. Finally, note that the _IN_, _P_, _EDF_ and _RSQ_ columns appear in the OUTEST= data set since the RSQUARE option is specified in the PROC REG statement.

**Example 61.3. Regression with Quantitative and Qualitative Variables**

At times it is desirable to have independent variables in the model that are qualitative rather than quantitative. This is easily handled in a regression framework. Regression uses qualitative variables to distinguish between populations. There are two main advantages of fitting both populations in one model. You gain the ability to test for different slopes or intercepts in the populations, and more degrees of freedom are available for the analysis.

Regression with qualitative variables is different from analysis of variance and analysis of covariance. Analysis of variance uses qualitative independent variables only. Analysis of covariance uses quantitative variables in addition to the qualitative variables in order to account for correlation in the data and reduce MSE; however, the quantitative variables are not of primary interest and merely improve the precision of the analysis.

Consider the case where $Y_i$ is the dependent variable, $X_1i$ is a quantitative variable, $X_2i$ is a qualitative variable taking on values 0 or 1, and $X_1iX_2i$ is the interaction. The variable $X_2i$ is called a dummy, binary, or indicator variable. With values 0 or 1, it distinguishes between two populations. The model is of the form

$$Y_i = \beta_0 + \beta_1X_1i + \beta_2X_2i + \beta_3X_1iX_2i + \epsilon_i$$

for the observations $i = 1, 2, \ldots, n$. The parameters to be estimated are $\beta_0$, $\beta_1$, $\beta_2$, and $\beta_3$. The number of dummy variables used is one less than the number of qualitative levels. This yields a nonsingular $X'X$ matrix. See Chapter 10 of Neter, Wasserman, and Kutner (1990) for more details.

An example from Neter, Wasserman, and Kutner (1990) follows. An economist is investigating the relationship between the size of an insurance firm and the speed at which they implement new insurance innovations. He believes that the type of firm may affect this relationship and suspects that there may be some interaction between the size and type of firm. The dummy variable in the model allows the two firms to have different intercepts. The interaction term allows the firms to have different slopes as well.

In this study, $Y_i$ is the number of months from the time the first firm implemented the innovation to the time it was implemented by the $ith$ firm. The variable $X_1i$ is the size of the firm, measured in total assets of the firm. The variable $X_2i$ denotes the firm type and is 0 if the firm is a mutual fund company and 1 if the firm is a stock
The dummy variable allows each firm type to have a different intercept and slope.

The previous model can be broken down into a model for each firm type by plugging in the values for $X_2_i$. If $X_2_i = 0$, the model is

$$Y_i = \beta_0 + \beta_1 X_1_i + \epsilon_i$$

This is the model for a mutual company. If $X_2_i = 1$, the model for a stock firm is

$$Y_i = (\beta_0 + \beta_2) + (\beta_1 + \beta_3)X_1_i + \epsilon_i$$

This model has intercept $\beta_0 + \beta_2$ and slope $\beta_1 + \beta_3$.

The data follow. Note that the interaction term is created in the DATA step since polynomial effects such as size*type are not allowed in the MODEL statement in the REG procedure.

Parameter Estimates

| Variable | DF | Parameter Estimate | Standard Error | t Value | Pr > |t| |
|----------|----|--------------------|----------------|---------|-------|
| Intercept| 1  | 33.83837           | 2.44065        | 13.86   | <.0001|
| size     | 1  | -0.10153           | 0.01305        | -7.78   | <.0001|
| type     | 1  | 8.13125            | 3.65405        | 2.23    | 0.0408|
| sizetype | 1  | -0.00041714        | 0.01833        | -0.02   | 0.9821|

The overall $F$ statistic is significant ($F=45.490, p<0.0001$). The interaction term is not significant ($t=-0.023, p=0.9821$). Hence, this term should be removed and the model re-fitted, as shown in the following statements.

```r
delete sizetype;
print;
run;
```

The DELETE statement removes the interaction term (sizetype) from the model. The new ANOVA table is shown in Output 61.3.2.
The overall $F$ statistic is still significant ($F=72.497$, $p<0.0001$). The intercept and the coefficients associated with size and type are significantly different from zero ($t=18.675$, $p<0.0001$; $t=-11.443$, $p<0.0001$; $t=5.521$, $p<0.0001$, respectively). Notice that the $R^2$ did not change with the omission of the interaction term.

The fitted model is

$$\text{time} = 33.87 - 0.102 \times \text{size} + 8.055 \times \text{type}$$

The fitted model for a mutual fund company ($X2_i = 0$) is

$$\text{time} = 33.87 - 0.102 \times \text{size}$$

and the fitted model for a stock company ($X2_i = 1$) is

$$\text{time} = (33.87 + 8.055) - 0.102 \times \text{size}$$

So the two models have different intercepts but the same slope.

Now plot the residual versus predicted values using the firm type as the plot symbol (PLOT=TYPE); this can be useful in determining if the firm types have different residual patterns. PROC REG does not support the plot y*x=type syntax for high-resolution graphics, so use PROC GPLOT to create Output 61.3.3. First, the
OUTPUT statement saves the residuals and predicted values from the new model in the OUT= data set.

```plaintext
output out=out r=r p=p;
run;
symbol1 v='0' c=blue f=swissb;
symbol2 v='1' c=yellow f=swissb;
axis1 label=(angle=90);
proc gplot data=out;
   plot r*p=type / nolegend vaxis=axis1 cframe=ligr;
   plot p*size=type / nolegend vaxis=axis1 cframe=ligr;
run;
```

Output 61.3.3. Plot of Residual vs. Predicted Values

The residuals show no major trend. Neither firm type by itself shows a trend either. This indicates that the model is satisfactory.

A plot of the predicted values versus size appears in Output 61.3.4, where the firm type is again used as the plotting symbol.
Example 61.4. Displaying Plots for Simple Linear Regression

This example introduces the basic PROC REG graphics syntax used to produce a standard plot of data from the aerobic fitness data set (Example 61.1 on page 3924). A simple linear regression of Oxygen on RunTime is performed, and a plot of Oxygen*RunTime is requested. The fitted model, the regression line, and the four default statistics are also displayed in Output 61.4.1.

```
data fitness;
  set fitness;
  label Age   = 'age(years)'
           Weight = 'weight(kg)'
           Oxygen = 'oxygen uptake(ml/kg/min)'
           RunTime = '1.5 mile time(min)'
           RestPulse='rest pulse'
           RunPulse = 'running pulse'
           MaxPulse = 'maximum running pulse';
proc reg data=fitness;
  model Oxygen=RunTime;
  plot Oxygen*RunTime / cframe=ligr;
run;
```
Example 61.5. Creating a $C_p$ Plot

The $C_p$ statistics for model selection are plotted against the number of parameters in the model, and the CHOCKING= and CMALLOWS= options draw useful reference lines. Note the four default statistics in the plot margin, the default model equation, and the default legend in Output 61.5.1.

```plaintext
title 'Cp Plot with Reference Lines';
symbol1 c=green;
proc reg data=fitness;
    model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
        / selection=rsquare noprint;
    plot cp.*np.
        / chocking=red cmallows=blue
        vaxis=0 to 15 by 5 cframe=ligr;
run;
```
Using the criteria suggested by Hocking (1976) (see the section “Dictionary of PLOT Statement Options” beginning on page 3844), Output 61.5.1 indicates that a 6-variable model is a reasonable choice for doing parameter estimation, while a 5-variable model may be suitable for doing prediction.

**Example 61.6. Controlling Plot Appearance with Graphic Options**

This example uses model fit summary statistics from the OUTEST= data set to create a plot for a model selection analysis. Global graphics statements and PLOT statement options are used to control the appearance of the plot.

``` SAS
options ctitle=black htitle=3.5pct ftitle=swiss
c text=magenta htext =3.0pct ftext =swiss
c back =ligr border;
symboll v=circle c=red h=1 w=2;
title1 'Selection=Rsquare';
title2 'plot Rsquare versus the number of parameters P in '
   'each model';

goptions ctitle=black htitle=3.5pct ftitle=swiss
c text=magenta htext =3.0pct ftext =swiss
c back =ligr border;
symboll v=circle c=red h=1 w=2;
title1 'Selection=Rsquare';
title2 'plot Rsquare versus the number of parameters P in '
   'each model';

proc reg data=fitness;
  model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse
       / selection=rsquare noprint;
  plot rsq.*np.
       / aic bic edf gmsep jp np pc sbc sp
  haxis=2 to 7 by 1
```

**Output 61.5.1. $C_p$ Plot**

![Cp Plot with Reference Lines](image)

Oxygen = 102.93 - 0.227 Age - 0.0742 Weight - 2.6287 RunTime - 0.3696 RunPulse
- 0.0215 RestPulse + 0.3032 MaxPulse
In the GOPTIONS statement,

- \textsc{b}ORDER frames the entire display
- \textsc{c}BACK= specifies the background color
- \textsc{c}TEXT= selects the default color for the border and all text, including titles, footnotes, and notes
- \textsc{c}TITLE= specifies the title, footnote, note, and border color
- \textsc{h}TEXT= specifies the height for all text in the display
- \textsc{h}TITLE= specifies the height for the first title line
- \textsc{f}TEXT= selects the default font for all text, including titles, footnotes, notes, the model label and equation, the statistics, the axis labels, the tick values, and the legend
- \textsc{f}TITLE= specifies the first title font

For more information on the GOPTIONS statement and other global graphics statements, refer to \textit{SAS/GRAPH Software: Reference}.

\textbf{Output 61.6.1.} Controlling Plot Appearance and Plotting OUTEST= Statistics

![Plot depicting the relationship between Rsquare and the number of parameters P in each model]
In Output 61.6.1, note the following:

- The PLOT statement option CTEXT= affects all text not controlled by the CTITLE= option in the GOPTIONS statement. Hence, the GOPTIONS statement option CTEXT=MAGENTA has no effect. Therefore, the color of the title is black and all other text is blue.
- The area enclosed by the axes and the frame has a white background, while the background outside the plot area is gray.
- The MODELHT= option allows the entire model equation to fit on one line.
- The STATHT= option allows the statistics in the margin to fit in one column.
- The displayed statistics and the fitted model equation refer to the selected model. See the “Traditional High-Resolution Graphics Plots” section beginning on page 3840 for more information.

Example 61.7. Plotting Model Diagnostic Statistics

This example illustrates how you can display diagnostics for checking the adequacy of a regression model. The following statements plot the studentized deleted residuals against the observation number for the full model. Vertical reference lines at \( \pm t_{inv}(0.95, n - p - 1) = \pm 1.714 \) are added to identify possible outlying Oxygen values. A vertical reference line is displayed at zero by default when the RSTUDENT option is specified. The graph is shown in Output 61.7.1. Observations 15 and 17 are indicated as possible outliers.

```sas
title 'Check for Outlying Observations';
symbol v=dot h=1 c=green;
proc reg data=fitness;
   model Oxygen=Age Weight RunTime RunPulse RestPulse MaxPulse;
   plot rstudent.*obs./ vref=-1.714 1.714 cvref=blue lvref=1
       href=0 to 30 by 5 chref=red cframe=ligr;
run;
```
Example 61.8. Creating PP and QQ Plots

The following program creates probability-probability plots and quantile-quantile plots of the residuals (Output 61.8.1 and Output 61.8.2, respectively). An annotation data set is created to produce the (0,0)–(1,1) reference line for the PP-plot. Note that the NOSTAT option for the PP-plot suppresses the statistics that would be displayed in the margin.

**Example 61.9. Displaying Confidence and Prediction Intervals**

This example illustrates how you can use shorthand commands to plot the dependent variable, the predicted value, and the 95% confidence or prediction intervals against a regressor. The following statements use the PRED option to create a plot with prediction intervals; the CONF option works similarly. Results are displayed in **Output 61.9.1**. Note that the statistics displayed by default in the margin are suppressed while three other statistics are exhibited.

```plaintext
legend1 position=(bottom left inside)
   across=1 cborder=red offset=(0,0)
   shape=symbol(3,1) label=none
   value=(height=.8);
title 'Prediction Intervals';
symbol1 c=yellow v=- h=1;
symbol2 c=red;
symbol3 c=blue;
symbol4 c=blue;

proc reg data=fitness;
   model Oxygen=RunTime / noprint;
   plot Oxygen*RunTime / pred nostat mse aic bic
      caxis=red ctext=blue cframe=ligr
      legend=legend1 modellab=' '; run;
```
Output 61.9.1. Prediction Intervals

Plots can be produced with both confidence and prediction intervals using the following statement.

```
plot Oxygen*RunTime / conf pred;
```

     'independent variables') cframe=white;

proc reg data=acetyl outvif
  outest=b ridge=0 to 0.02 by .002;
  model x4=x1 x2 x3 x1x2 x1x1/noprint;
  plot / ridgeplot nomodel legend=legend2 nostat
    vref=0 lvref=1 cvref=blue cframe=ligr;
run;
```

The results produced by the RIDGEPLOT option are shown in Output 61.10.1. The OUTVIF option outputs the variance inflation factors to the OUTEST= data set, which is used in Example 61.11.

**Output 61.10.1.** Using the RIDGEPLOT Option for Ridge Regression

![Ridge Trace of Acetylene Data](image)

If you specify the experimental ODS GRAPHICS statement (see the “ODS Graphics” section on page 3922), a plot of ridge traces is produced, without the need to specify the RIDGEPLOT option in the PLOT statement. For general information about
ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” The following statements provide an example:

```plaintext
ods html;
ods graphics on;
proc reg data=acetyl outest=b ridge=0 to 0.02 by .002;
    model x4=x1 x2 x3 x1x2 x1x1/noprint;
run;
ods graphics off;
ods html close;
```

**Output 61.10.2.** Ridge Traces Produced with ODS Graphics (Experimental)

---

**Example 61.11. Plotting Variance Inflation Factors**

This example uses the REG procedure to create plots from a data set. The variance inflation factors (output by the OUTVIF option in the previous example) are plotted against the ridge regression control values $k$. The following statements create Output 61.11.1:
data b (keep=_RIDGE_ x1-x3 x1x2 x1x1);
  set b;
  if _TYPE_='RIDGEVIF';
  label x1='variance inflation factor';
run;

legend3 position=(top right inside) across=3
cborder=black cframe=white
  label=(color=blue position=(top center)
    'independent variables')
  value=('X1' 'X2' 'X3' 'X1X2' 'X1X1');
symbol1 c=blue /*v=circle */;
symbol2 c=yellow /*v=x */;
symbol3 c=cyan /*v=triangle*/;
symbol4 c=green /*v=square */;
symbol5 c=orange /*v=diamond */;
title 'Variance Inflation Factors of Acetylene Data';

proc reg data=b;
  var _RIDGE_ x3 x1x2 x1x1;
  model x1=x2 / noprint;
  plot (x1 x2 x3 x1x2 x1x1)*_RIDGE_
    / nomodel nostat legend=legend3 overlay
    vaxis = 0 to 75 by 25 cframe=ligr
    haxis = 0 to .02 by .002;
  footnote "Note: the VIF at k=0 is 7682 for X1, 
    "6643 for X1X1, 345 for X1X2, and 320 for X2";
run;

The GPLOT procedure can create the same plot with the following statements. The
resulting display is not shown in this report.

axis1 label=(a=90 r=0 'variance inflation factor')
  order=(0 to 75 by 25) minor=none;
proc gplot data=b;
  plot (x1 x2 x3 x1x2 x1x1)*_RIDGE_
    / legend=legend3 overlay frame
    vaxis = axis1
    haxis = 0 to .02 by .002 hminor=0;
  footnote "Note: the VIF at k=0 is 7682 for X1, 
    "6643 for X1X1, 345 for X1X2, and 320 for X2";
run;
Example 61.12. ODS Graphics

This example highlights the use of ODS for creating statistical graphs with the REG procedure. The USPopulation example is revisited, showing how these graphics can be used to enrich the analysis. Note that the ODS graphics available with PROC REG can be obtained in addition to the graphics you can request with the PLOT statement.

To request the ODS plots you need to specify the experimental ODS GRAPHICS statement. For general information about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the REG procedure, see the “ODS Graphics” section on page 3922.

The following statements produce the default plots:

```plaintext
ods html;
ods graphics on;

proc reg data=USPopulation;
   Linear: model Population=Year;
   Quadratic: model Population=Year YearSq;
run;quit;

ods graphics off;
ods html close;
```
Output 61.12.1. Fit Diagnostics For the Model Linear in Year (Experimental)

When the experimental ODS graphics are in effect, the fit diagnostic panel Output 61.12.1 is produced by default. These diagnostic plots suggest that while the linear model captures the increasing trend in the data, the model could be significantly improved by adding a term which is quadratic in the variable year:

- The plots of residual and studentized residual versus predicted value show a clear quadratic pattern.
- The plot of studentized residual versus leverage seems to indicate that there are two outlying data points. However, the plot of Cook’s D distance versus observation number reveals that these two points are just the data points for the endpoint years 1790 and 2000. These points show up as apparent outliers be-
cause the departure of the linear model from the underlying quadratic behavior in the data shows up most strongly at these endpoints.

- The normal quantile plot of the residuals and the residual histogram are not consistent with the assumption of gaussian errors. This occurs as the residuals themselves still contain the quadratic behavior that is not captured by the linear model.

- The plot of the dependent variable versus the predicted value exhibits a quadratic form around the 45 degree line which represents a perfect fit.

- The “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals shows that the spread in the residuals is no greater than the spread in the centered fit. For inappropriate models, the spread of the residuals in such a plot is often greater than the spread of the centered fit. In this case, the RF plot shows that the linear model does indeed capture the increasing trend in the data, and hence accounts for much of the variation in the response.

Output 61.12.2. Residual By Year For the Model Linear in Year (Experimental)

The plot of residual versus the regressor shown in Output 61.12.2 also indicates the need for a quadratic term in the model. There is a strong quadratic trend still remain-
ing in the residuals. Note for models with multiple regressors the plots of residual versus each of the regressors are displayed in panels with up to six plots per panel.

**Output 61.12.3.** Fit Plot with Confidence Band and Prediction Limits  
(Experimental)

Output 61.12.3 shows as scatterplot of the data overlayed with the regression line, and 95% confidence band and prediction limits. Note that this plot also indicates that the model fails to capture the quadratic nature of the data. This plot is produced for models containing a single regressor. You can use the ALPHA= option in the model statement to change the significance level of the confidence band and prediction limits.
Output 61.12.4. Fit Diagnostics For the Model Linear in Year (Experimental)

By contrast, Output 61.12.4 shows the fit diagnostics panel for the model that includes a quadratic term for year. These diagnostics indicate that this model is significantly more successful than the corresponding linear model:

- The plots of residuals and studentized residuals versus predicted values exhibit no obvious patterns.
- The points on the plot of the dependent variable versus the predicted values lie along a 45 degree line, indicating that the model successfully predicts the behavior of the dependent variable.
- The plot of studentized residual versus leverage shows that the years 1790 and 2000 are leverage points with 2000 showing up as an outlier. This is confirmed by the plot of Cook’s D distance versus observation number. This suggests that
while the quadratic model fits the current data well, the model may not be quite so successful over a wider range of data. You might want to investigate whether the population trend over the last couple of decades is growing slightly faster than quadratically.

If you want to obtain the plots in the Diagnostics Panel as individual plots, you can do so by specifying the PLOTS(UNPACKPANELS) option in the PROC REG statement. The following statements provide an example:

```plaintext
ods html;
ods graphics on;
proc reg data=USPopulation plots(unpackpanels);
   Quadratic:model Population=Year YearSq;
run;quit;
ods graphics off;
ods html close;
```

**Output 61.12.5.** Residual Histogram (Experimental)

The residual histogram is shown in **Output 61.12.5.**

</table>
The main purpose of robust regression is to detect outliers and provide resistant (stable) results in the presence of outliers. In order to achieve this stability, robust regression limits the influence of outliers. Historically, three classes of problems have been addressed with robust regression techniques:

- problems with outliers in the $y$-direction (response direction)
- problems with multivariate outliers in the $x$-space (i.e., outliers in the covariate space, which are also referred to as leverage points)
- problems with outliers in both the $y$-direction and the $x$-space

Many methods have been developed in response to these problems. However, in statistical applications of outlier detection and robust regression, the methods most commonly used today are Huber M estimation, high breakdown value estimation, and combinations of these two methods. The new ROBUSTREG procedure in this version provides four such methods: M estimation, LTS estimation, S estimation, and MM estimation.

1. M estimation was introduced by Huber (1973), and it is the simplest approach both computationally and theoretically. Although it is not robust with respect to leverage points, it is still used extensively in analyzing data for which it can be assumed that the contamination is mainly in the response direction.

2. Least Trimmed Squares (LTS) estimation is a high breakdown value method introduced by Rousseeuw (1984). The breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. The performance of this method was improved by the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000).

3. S estimation is a high breakdown value method introduced by Rousseeuw and Yohai (1984). With the same breakdown value, it has a higher statistical efficiency than LTS estimation.

4. MM estimation, introduced by Yohai (1987), combines high breakdown value estimation and M estimation. It has both the high breakdown property and a higher statistical efficiency than S estimation.

Experimental graphics are now available with the ROBUSTREG procedure. For more information, see the section “ODS Graphics” on page 4013.
### Getting Started

The following examples demonstrate how you can use the ROBUSTREG procedure to fit a linear regression model and conduct outlier and leverage point diagnostics.

#### M Estimation

This example shows how you can use the ROBUSTREG procedure to do M estimation, which is a commonly used method for outlier detection and robust regression when contamination is mainly in the response direction.

```r
data stack;
  input x1 x2 x3 y;
  datalines;
  80 27 89 42
  80 27 88 37
  75 25 90 37
  62 24 87 28
  62 22 87 18
  62 23 87 18
  62 24 93 19
  62 24 93 20
  58 23 87 15
  58 18 80 14
  58 18 89 14
  58 17 88 13
  58 18 82 11
  58 19 93 12
  50 18 89 8
  50 18 86 7
  50 19 72 8
  50 19 79 8
  50 20 80 9
  56 20 82 15
  70 20 91 15
;
```

The data set `stack` is the well-known stackloss data set presented by Brownlee (1965). The data describe the operation of a plant for the oxidation of ammonia to nitric acid and consist of 21 four-dimensional observations. The explanatory variables for the response `stackloss` (`y`) are the rate of operation (`x1`), the cooling water inlet temperature (`x2`), and the acid concentration (`x3`).

The following ROBUSTREG statements analyze the data:

```r
proc robustreg data=stack;
  model y = x1 x2 x3 / diagnostics leverage;
  id x1;
  test x3;
run;
```
By default, the procedure does M estimation with the bisquare weight function, and it uses the median method for estimating the scale parameter. The MODEL statement specifies the covariate effects. The DIAGNOSTICS option requests a table for outlier diagnostics, and the LEVERAGE option adds leverage point diagnostic results to this table for continuous covariate effects. The ID statement specifies that variable x1 is used to identify each observation in this table. If the ID statement is omitted, the observation number is used to identify the observations. The TEST statement requests a test of significance for the covariate effects specified. The results of this analysis are displayed in the following figures.

**Figure 62.1.** Model Fitting Information and Summary Statistics

Figure 62.1 displays the model fitting information and summary statistics for the response variable and the continuous covariates. The columns labeled Q1, Median, and Q3 provide the lower quantile, median, and upper quantile. The column labeled MAD provides a robust estimate of the univariate scale, which is computed as the corrected median absolute deviation (MAD). The columns labeled Mean and Standard Deviation provide the usual mean and standard deviation. Large difference between the standard deviation and the MAD for a variable indicates some big jumps for this variable. In the stackloss data, the stackloss (response variable y) has the biggest difference between the standard deviation and the dispersion.

**Figure 62.2.** Model Parameter Estimates

The ROBUSTREG Procedure

</tbody>
</table>
Figure 62.2 displays the table of robust parameter estimates, standard errors, and confidence limits. The row labeled Scale provides a point estimate of the scale parameter in the linear regression model, which is obtained by the median method. See the section “M Estimation” on page 3993 for more information about scale estimation methods. For the stackloss data, M estimation yields the fitted linear model:

\[
\hat{y} = -42.2845 + 0.9276x1 + 0.6507x2 - 0.1123x3
\]

Figure 62.3. Diagnostics

Figure 62.3 displays outlier and leverage point diagnostics. Standardized robust residuals are computed based on the estimated parameters. Both the Mahalanobis distance and the robust MCD distance are displayed. Outliers and leverage points, identified with asterisks, are defined by the standardized robust residuals and robust MCD distances which exceed the corresponding cutoff values displayed in the diagnostics profile. Observations 4 and 21 are outliers because their standardized robust residuals exceed the cutoff value in absolute value. The procedure detects 4 observations with high leverage, which is contributed mainly by x1, especially for the first three observations. This can be verified by the definition of the robust MCD distance in the section “Robust Multivariate Location and Scale Estimates” on page 4009. Leverage points (points with high leverage) with smaller standardized robust residuals than the cutoff value in absolute value are called good leverage points; otherwise, called bad leverage points. Observations 21 is a bad leverage point.

Two particularly useful plots for revealing outliers and leverage points are a scatter plot of the standardized robust residuals against the robust distances (RDPLOT) and a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT).

For the stackloss data, the following statements produce the RDPLOT in Figure 62.4 and the DDPLOT in Figure 62.5. The histogram and the normal quantile-quantile plots for the standardized robust residuals are also created with the
RESHISTOGRAM and RESQQPLOT options in the PROC statement. See Figure 62.6 and Figure 62.7.

**Figure 62.4.** RDPLOT for Stackloss Data (Experimental)

**Figure 62.5.** DDPLOT for Stackloss Data (Experimental)
Figure 62.6. Histogram (Experimental)

Figure 62.7. Q-Q PLOT (Experimental)
ods html;
ods graphics on;

proc robustreg data=stack
  plots=(rdplot ddplot reshistogram resqqplot);
  model y = x1 x2 x3;
run;

ods graphics off;
ods html close;

These plots are helpful in identifying outliers, good, and bad high leverage points.

These graphical displays are requested by specifying the experimental ODS GRAPHICS statement and the experimental PLOT | PLOTS= option in the PROC statement. For general information about ODS graphics, see Chapter 15, “Statistical Graphics Using ODS.” For specific information about the graphics available in the ROBUSTREG procedure, see the section “ODS Graphics” on page 4013.

The ROBUSTREG Procedure
  Goodness-of-Fit

<table>

<td>0.3683</td>
<td></td>
</tr>
</tbody>
</table>

Figure 62.9. Test of Significance

Figure 62.9 displays the test results requested by the TEST statement. The ROBUSTREG procedure conducts two robust linear tests, the $\rho$-test and the $R_{n}^{2}$-test. See the section “Linear Tests” on page 3998 for information on how the procedure computes test statistics and the correction factor $\lambda$. You can conclude that the effect $x3$ is not significant.
For the bisquare weight function, the default constant \( c = 4.685 \) such that the asymptotic efficiency of the M estimates is 95\% with the Gaussian distribution. See the section “M Estimation” on page 3993 for details. The smaller the constant \( c \), the lower the asymptotic efficiency but the sharper the M estimate as an outlier detector. For the stackloss data set, you could consider using a sharper outlier detector.

In the following invocation of the ROBUSTREG procedure, a smaller constant, e.g. \( c = 3.5 \), is used.

```plaintext
proc robustreg method=m(wf=bisquare(c=3.5)) data=stack;
   model y = x1 x2 x3 / diagnostics leverage;
   id   x1;
   test x3;
run;
```

Figure 62.11 displays outlier and leverage point diagnostics with the constant $c = 3.5$. Besides observations 4 and 21, observations 1 and 3 are also detected as outliers.

**LTS Estimation**

If the data are contaminated in the $x$-space, M estimation does not do well. The following example shows how you can use LTS estimation to deal with this situation.

```sas
data hbk;
  input index$ x1 x2 x3 y @@;
datalines;
1 10.1 19.6 28.3 9.7 39 2.1 0.0 1.2 -0.7
2 9.5 20.5 28.9 10.1 40 0.5 2.0 1.2 -0.5

;
```

The data set hbk is an artificial data set generated by Hawkins, Bradu, and Kass (1984). Both ordinary least squares (OLS) estimation and M estimation (not shown...
here) suggest that observations 11 to 14 are serious outliers. However, these four observations were generated from the underlying model, whereas observations 1 to 10 were contaminated. The reason that OLS estimation and M estimation do not pick up the contaminated observations is that they cannot distinguish good leverage points (observations 11 to 14) from bad leverage points (observations 1 to 10). In such cases, the LTS method identifies the true outliers.

The following statements invoke the ROBUSTREG procedure with the LTS estimation method.

```plaintext
proc robustreg data=hbk fwls method=lts;
  model y = x1 x2 x3 / diagnostics leverage;
  id index;
run;
```

**Figure 62.12.** Model Fitting Information and Summary Statistics

Figure 62.12 displays the model fitting information and summary statistics for the response variable and independent covariates.

**Figure 62.13.** LTS Profile

Figure 62.13 displays information about the LTS fit, which includes the breakdown value of the LTS estimate. Roughly speaking, the breakdown value is a measure of the proportion of contamination that an estimation method can withstand and still maintain its robustness. In this example the LTS estimate minimizes the sum of 57
smallest squares of residuals. It can still pick up the right model if the remaining 18 observations are contaminated. This corresponds to the breakdown value around 0.25, which is set as the default.

Figure 62.16. Final Weighted LS Estimates

Figure 62.16 displays the final weighted least squares estimates. These estimates are least squares estimates computed after deleting the detected outliers.

Syntax

```
PROC ROBUSTREG < options >;
   BY variables;
   CLASS variables;
   ID variables;
   MODEL response = <effects> < / options >;
   OUTPUT < OUT= SAS-data-set > < / options >;
   PERFORMANCE < / options >;
   TEST 'label' effects;
   WEIGHT variable;
```

The PROC ROBUSTREG statement invokes the procedure. The METHOD= option in the PROC ROBUSTREG statement selects one of the four estimation methods, M, LTS, S, and MM. By default, Huber M estimation is used. The MODEL statement is required and specifies the variables used in the regression. Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure. The CLASS statement specifies which explanatory variables are treated as categorical. These variables are allowed in the MODEL statement only for M estimation, and not for other estimation methods. The ID statement names variables to identify observations in the outlier diagnostics tables. The WEIGHT statement identifies a variable in the input data set whose values are used to weight the observations. The OUTPUT statement creates an output data set containing final weights, predicted values, and residuals. The TEST statement requests robust linear tests for the model parameters. The PERFORMANCE statement tunes the performance of the procedure by using single or multiple processors available on the hardware. In one invocation of PROC ROBUSTREG, multiple OUTPUT and TEST statements are allowed.
PROC ROBUSTREG Statement

PROC ROBUSTREG <options> ;

The PROC ROBUSTREG statement invokes the procedure. You can specify the following options in the PROC ROBUSTREG statement.

COVOUT
 saves the estimated covariance matrix in the OUTEST= data set for M estimation and MM estimation.

DATA=SAS-data-set
 specifies the input SAS data set used by PROC ROBUSTREG. By default, the most recently created SAS data set is used.

FWLS
 requests that final weighted least squares estimators be computed.

INEST=SAS-data-set
 specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section “INEST= Data Set” on page 4011 for a detailed description of the contents of the INEST= data set.

ITPRINT
 displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the MODEL statement.

NAMELEN=n
 specifies the length of effect names in tables and output data sets to be n characters, where n is a value between 20 and 200. The default length is 20 characters.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
 specifies the sorting order for the levels of the classification variables (specified in the CLASS statement). This ordering determines which parameters in the model correspond to each level in the data. The following table explains how PROC ROBUSTREG interprets values of the ORDER= option.

<table>
<thead>
<tr>
<th>Value of ORDER=</th>
<th>Levels Sorted By</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>order of appearance in the input data set</td>
</tr>
<tr>
<td>FORMATTED</td>
<td>formatted value</td>
</tr>
<tr>
<td>FREQ</td>
<td>descending frequency count; levels with the most observations come first in the order</td>
</tr>
<tr>
<td>INTERNAL</td>
<td>unformatted value</td>
</tr>
</tbody>
</table>

By default, ORDER=FORMATTED. For FORMATTED and INTERNAL, the sort order is machine dependent. For more information on sorting order, refer to the chapter titled “The SORT Procedure” in the SAS Procedures Guide.
OUTEST=SAS-data-set specifies an output SAS data set containing the parameter estimates, and, if the COVOUT option is specified, the estimated covariance matrix. See the section “OUTEST= Data Set” on page 4011 for a detailed description of the contents of the OUTEST= data set.

SEED=number specifies the seed for the random number generator used to randomly select the subgroups and subsets for LTS and S estimation. By default or you specify zero, the ROBUSTREG procedure generates a seed between one and one billion.

METHOD= method type < (options) > specifies the estimation method and options specify some additional options for the estimation method. PROC ROBUSTREG provides four estimation methods: M estimation, LTS estimation, S estimation, and MM estimation. The default method is M estimation.

Since the LTS and S methods use subsampling algorithms, it is not suitable to apply these methods to an analysis with continuous independent variables which have only a few nonzero values or a few nonzero values within one BY group.

Options with METHOD=M

With METHOD=M, you can specify the following additional options:

ASYMPCOV=H1 | H2 | H3 specifies the type of asymptotic covariance computed for the M estimate. The three types are described in the section “Asymptotic Covariance and Confidence Intervals” on page 3997. By default, ASYMPCOV= H1.

CONVERGENCE=criterion <(EPS=value)> specifies a convergence criterion for the M estimate.

Table 62.2. Options to Specify Convergence Criteria

<table>
<thead>
<tr>
<th>Type</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>residual</td>
<td>CONVERGENCE= RESID</td>
</tr>
<tr>
<td>weight</td>
<td>CONVERGENCE= WEIGHT</td>
</tr>
<tr>
<td>coefficient</td>
<td>CONVERGENCE= COEF</td>
</tr>
</tbody>
</table>

By default, CONVERGENCE = COEF. You can specify the precision of the convergence can be specified with the EPS= option. By default, EPS=1.E−8.

MAXITER=n sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1000.

SCALE=scale type | value specifies the scale parameter or a method for estimating the scale parameter.
Table 62.3. Options to Specify Scale

<table>
<thead>
<tr>
<th>Scale</th>
<th>Option</th>
<th>Default d</th>
</tr>
</thead>
<tbody>
<tr>
<td>Median estimate</td>
<td>SCALE=MED</td>
<td></td>
</tr>
<tr>
<td>Tukey estimate</td>
<td>SCALE=TUKEY&lt;(D=d)&gt;</td>

<tr>
<td>Huber estimate</td>
<td>SCALE=HUBER&lt;(D=d)&gt;</td>
<td>2.5</td>
</tr>
<tr>
<td>Fixed constant</td>
<td>SCALE=value</td>
<td></td>
</tr>
</tbody>
</table>

By default, SCALE = MED.

WF | WEIGHTFUNCTION= function type

specifies the weight function used for the M estimate. The ROBUSTREG procedure provides ten weight functions, which are listed in the following table. You can specify the parameters in these functions with the A=, B=, and C= options. These functions are described in the section “M Estimation” on page 3993. The default weight function is bisquare.

Table 62.4. Options to Specify Weight Functions

<table>
<thead>
<tr>
<th>Weight Function</th>
<th>Option</th>
<th>Default a, b, c</th>
</tr>
</thead>
<tbody>
<tr>
<td>andrews</td>

</tr>
<tr>
<td>welsch</td>
<td>WF = WELSCH&lt;(C=c)&gt;</td>
<td>2.985</td>
</tr>
</tbody>
</table>

Options with METHOD=LTS

With METHOD=LTS, you can specify the following additional options:

CSTEP=n
specifies the number of C-steps for the LTS estimate. See the section “LTS Estimate” on page 4000 for how the default value is determined.

IADJUST=ALL | NONE
requests (IADJUST=ALL) or suppresses (IADJUST=NONE) the intercept adjustment for all estimates in the LTS-algorithm. By default, the intercept adjustment is used for data sets with less than 10000 observations. See the section “Algorithm” on page 4001 for details.

H=n
specifies the quantile for the LTS estimate. See the section “LTS Estimate” on page 4000 for how the default value is determined.
**NBEST=n**
specifies the number of best solutions kept for each subgroup during the computation of the LTS estimate. The default number is 10, which is the maximum number allowed.

**NREP=n**
specifies the number of repeats of least squares fit in subgroups during the computation of the LTS estimate. See the section “LTS Estimate” for how the default number is determined.

**SUBANALYSIS**
requests a display of the subgrouping information and parameter estimates within subgroups. This option may generate the following ODS tables:

<table>
<thead>
<tr>
<th>ODS Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BestEstimates</td>
<td>Best final estimates for LTS</td>
</tr>
<tr>
<td>BestSubEstimates</td>
<td>Best estimates for each subgroup</td>
</tr>
<tr>
<td>CStep</td>
<td>C-Step information for LTS</td>
</tr>
<tr>
<td>Groups</td>
<td>Grouping information for LTS</td>
</tr>
</tbody>
</table>

Some of these tables are data dependent.

**SUBGROUPSIZE=n**
specifies the data set size of the subgroups in the computation of the LTS estimate. The default number is 300.

**Options with METHOD=S**

With METHOD=S, you can specify the following additional options:

**ASYMPCOV=H1 | H2 | H3 | H4**
specifies the type of asymptotic covariance computed for the S estimate. The four types are described in the section “Asymptotic Covariance and Confidence Intervals” on page 4005. By default, ASYMPCOV= H4.

**CHIF= TUKEY | YOHAI**
specifies the \( \chi \) function for the S estimate. PROC ROBUSTREG provides two \( \chi \) functions, Tukey’s BISQUARE function and Yohai’s OPTIMAL function, which you can request with CHIF=TUKEY and CHIF=YOHAI, respectively. The default is Tukey’s bisquare function.

**EFF=value**
specifies the efficiency for the S estimate. The parameter \( k_0 \) in the \( \chi \) function is determined by this efficiency. The default efficiency is determined such that the consistent S estimate has the breakdown value of 25%.
**PROC ROBUSTREG Statement**

**MAXITER=n**
sets the maximum number of iterations for computing the scale parameter of the S estimate. By default, MAXITER=1000.

**NREP=n**
specifies the number of repeats of subsampling in the computation of the S estimate. See the section “Algorithm” on page 4004 for how the default number of repeats is determined.

**NOREFINE**
suppresses the refinement for the S estimate. See the section “Algorithm” on page 4004 for details.

**SUBSETSIZE=n**
specifies the size of the subset for the S estimate. See the section “Algorithm” on page 4004 for how its default value is determined.

**TOLERANCE=value**
specifies the tolerance for the S estimate of the scale. The default value is .001.

**Options with METHOD=MM**

With METHOD=MM, you can specify the following additional options:

**ASYMPCOV=H1 | H2 | H3 | H4**
specifies the type of asymptotic covariance computed for the MM estimate. The four types are described in the “Details” section. By default, ASYMPCOV= H4.

**BIAS<(ALPHA= number)>**
requests the bias test for the final MM estimate. See the section “Bias Test” on page 4008 for details about this test.

**CHIF= TUKEY | YOHAI**
selects the $\chi$ function for the MM estimate. PROC ROBUSTREG provides two $\chi$ functions: Tukey’s BISQUARE function and Yohai’s OPTIMAL function, which you can request with CHIF=TUKEY and CHIF=YOHAI, respectively. The default is Tukey’s bisquare function. This $\chi$ function is also used by the initial S estimate if you specify the INITEST=S option.

**CONVERGENCE=criterion <(EPS=number)>**
specifies a convergence criterion for the MM estimate.

<table>
<thead>
<tr>
<th>Type</th>
<th>Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>residual</td>
<td>CONVERGENCE= RESID</td>
</tr>
<tr>
<td>weight</td>
<td>CONVERGENCE= WEIGHT</td>
</tr>
<tr>
<td>coefficient</td>
<td>CONVERGENCE= COEF</td>
</tr>
</tbody>
</table>

By default, CONVERGENCE = COEF. You can specify the precision of the convergence with the EPS= option. By default, EPS=1.E–8.
**EFF=value**

specifies the efficiency for the MM estimate. The parameter $k_1$ in the $\chi$ function is determined by this efficiency. The default efficiency is set to 85\%, which corresponds to $k_1 = 3.440$ for CHIF=TUKEY or $k_1 = 0.868$ for CHIF=YOHAI.

**INITH=n**

specifies the integer $h$ for the initial LTS estimator used by the MM estimator. See the section “Algorithm” on page 4007 for how to specify $h$ and how the default is determined.

**INITEST= LTS | S**

specifies the initial estimator for the MM estimator. By default, the LTS estimator is used as the initial estimator for the MM estimator.

**K0=number**

specifies the parameter $k_0$ in the $\chi$ function for the MM estimate. For CHIF=TUKEY, the default is $k_0 = 2.9366$. For CHIF=YOHAI, the default is $k_0 = 0.7405$. These default values correspond to the 25\% breakdown value of the MM estimator.

**MAXITER=n**

sets the maximum number of iterations during the parameter estimation. By default, MAXITER=1000.

---

**BY Statement**

```
BY variables ;
```

You can specify a BY statement with PROC ROBUSTREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the ROBUSTREG procedure. The NOTSORTED option does not mean that the data are unsorted, but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in *SAS Language Reference: Concepts*. For more information on the DATASETS procedure, refer to the *SAS Procedures Guide*. 
CLASS Statement

CLASS variables ;

Explanatory variables that are classification variables rather than quantitative numeric variables must be listed in the CLASS statement. For each explanatory variable listed in the CLASS statement, indicator variables are generated for the levels assumed by the CLASS variable. If the CLASS statement is used, it must appear before the MODEL statement.

ID Statement

ID variables ;

When the diagnostics table is requested with the DIAGNOSTICS option in the MODEL statement, the variables listed in the ID statement are displayed besides the observation number. These variables can be used to identify each observation. If the ID statement is omitted, the observation number is used to identify the observations.

MODEL Statement

<label: > MODEL response = <effects> < / options > ;

Main effects and interaction terms can be specified in the MODEL statement, as in the GLM procedure. Class variables are not allowed in the MODEL statement when you specify MM estimation or LTS estimation using the METHOD= option in the PROC statement.

The optional label is used to label output from the matching MODEL statement.

Options

You can specify the following options for the model fit.

ALPHA=value

specifies the significance level for the confidence intervals for regression parameters. The value must be between 0 and 1. By default, ALPHA = 0.05.

CORRB

produces the estimated correlation matrix of the parameter estimates.

COVB

produces the estimated covariance matrix of the parameter estimates.

CUTOFF=value

specifies the multiplier of the cutoff value for outlier detection. By default, CUTOFF = 3.

DIAGNOSTICS<(ALL)> 

requests the outlier diagnostics. By default, only observations identified as outliers or leverage points are displayed. To request that all observations be displayed, specify the ALL option.
 Chapter 62. The ROBUSTREG Procedure

ITPRINT

displays the iteration history for the iteratively reweighted least squares algorithm used by M and MM estimation. You can also use this option in the PROC statement.

LEVERAGE<(CUTOFF=value | CUTOFFALPHA=value | QUANTILE=n)> requests an analysis of leverage points for the continuous covariates. The results are added to the diagnostics table, which you can request with the DIAGNOSTICS option in the MODEL statement. You can specify the cutoff value for leverage point detection with the CUTOFF= option. The default cutoff value is $\sqrt{\chi^2_{p,1-\alpha}}$, where $\alpha$ can be specified with the CUTOFFALPHA= option. By default, $\alpha = .025$. You can use the QUANTILE= option to specify the quantile to be minimized for the MCD algorithm used for the leverage point analysis. By default, QUANTILE=$[(3n + p + 1)/4]$, where $n$ is the number of observations and $p$ is the number of independent variables. The LEVERAGE option is ignored if the model includes class variables as covariates.

Since the MCD algorithm uses subsampling, it is not suitable to apply the leverage point analysis to continuous variables which have only a few nonzero values or a few nonzero values within one BY group.

NOGOODFIT

suppresses the computation of goodness-of-fit statistics.

NOINT

specifies no-intercept regression.

SINGULAR=value

specifies the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least-squares estimates. Roughly, the test requires that a pivot be at least this value times the original diagonal value. By default, SINGULAR = 1.E−12.

OUTPUT Statement

OUTPUT <OUT=SAS-data-set> keyword=name <…keyword=name> 

The OUTPUT statement creates an output SAS data set containing statistics calculated after fitting the model. At least one specification of the form keyword=name is required.

All variables in the original data set are included in the new data set, along with the variables created with keyword options in the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a permanent SAS data set, you must specify a two-level name (refer to SAS Language Reference: Concepts for more information on permanent SAS data sets).

The following specifications can appear in the OUTPUT statement:

OUT=SAS-data-set specifies the new data set. By default, the procedure uses the DATAn convention to name the new data set.
keyword=name specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

**LEVERAGE** specifies a variable to indicate leverage points. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the PROC statement. See the section “Leverage Point and Outlier Detection” on page 4010 for how to define LEVERAGE.

**OUTLIER** specifies a variable to indicate outliers. See the section “Leverage Point and Outlier Detection” on page 4010 for how to define OUTLIER.

**PREDICTED | P** specifies a variable to contain the estimated response.

**RESIDUAL | R** specifies a variable to contain the residuals

\[ y_i - x_i^T b \]

**SRESIDUAL | SR** specifies a variable to contain the standardized residuals

\[ \frac{y_i - x_i^T b}{\hat{\sigma}} \]

**STDP** specifies a variable to contain the estimates of the standard errors of the estimated response.

**WEIGHT** specifies a variable to contain the computed final weights.

---

**PERFORMANCE Statement**

You use the PERFORMANCE statement to specify options that tune the performance of PROC ROBUSTREG. By default these options are chosen to maximize performance. See Chen (2002) for some empirical results.

```
PERFORMANCE <options> ;
```

The following option is available:

**CPUCOUNT=n**

specifies the number of threads to use in the computation of LTS or S estimation (initial LTS or S estimation for MM estimation). By default this will be equal to the number of processors on the hardware.
TEST Statement

<label: >TEST effects ;

With M estimation and MM estimation, the TEST statement provides a means for obtaining a test for the canonical linear hypothesis concerning the model parameters:

$$\theta_j = 0, \ j = q + 1, \ldots, p$$

where $p$ is the total number of parameters in the model, and $q$ is the number of parameters for testing of significance.

PROC ROBUSTREG provides two kinds of robust tests: the $r^2$-test and the $R^2_n$-test. They are described in the “Details” section. No test is available for LTS and S estimation.

The optional label is used to label output from the corresponding TEST statement.

WEIGHT Statement

WEIGHT variable ;

The WEIGHT statement specifies a weight variable in the input data set.

If you want to use fixed weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model.

Details

This section describes the statistical and computational aspects of the ROBUSTREG procedure. The following notation is used throughout this section.

Let $X = (x_{ij})$ denote an $n \times p$ matrix, $y = (y_1, \ldots, y_n)^T$ a given $n$-vector of responses, and $\theta = (\theta_1, \ldots, \theta_p)^T$ an unknown $p$-vector of parameters or coefficients whose components are to be estimated. The matrix $X$ is called the design matrix. Consider the usual linear model

$$y = X\theta + e$$

where $e = (e_1, \ldots, e_n)^T$ is an $n$-vector of unknown errors. It is assumed that (for a given $X$) the components $e_i$ of $e$ are independent and identically distributed according to a distribution $L(\cdot/\sigma)$, where $\sigma$ is a scale parameter (usually unknown). The vector of residuals for a given value of $\hat{\theta}$ is denoted by $r = (r_1, \ldots, r_n)^T$ and the $i$th row of the matrix $X$ is denoted by $x_i^T$. 
M Estimation

M estimation in the context of regression was first introduced by Huber (1973) as a result of making the least squares approach robust. Although M estimators are not robust with respect to leverage points, they are popular in applications where leverage points are not an issue.

Instead of minimizing a sum of squares of the residuals, a Huber-type M estimator \( \hat{\theta}_M \) of \( \theta \) minimizes a sum of less rapidly increasing functions of the residuals:

\[
Q(\theta) = \sum_{i=1}^{n} \rho\left(\frac{r_i}{\sigma}\right)
\]

where \( r = y - X\theta \). For the ordinary least squares estimation, \( \rho \) is the quadratic function.

If \( \sigma \) is known, by taking derivatives with respect to \( \theta \), \( \hat{\theta}_M \) is also a solution of the system of \( p \) equations:

\[
\sum_{i=1}^{n} \psi\left(\frac{r_i}{\sigma}\right)x_{ij} = 0, \ j = 1, \ldots, p
\]

where \( \psi = \rho' \). If \( \rho \) is convex, \( \hat{\theta}_M \) is the unique solution.

The ROBUSTREG procedure solves this system by using iteratively reweighted least squares (IRLS). The weight function \( w(x) \) is defined as

\[
w(x) = \frac{\psi(x)}{x}
\]

The ROBUSTREG procedure provides ten kinds of weight functions (corresponding to ten \( \rho \)-functions) through the WEIGHTFUNCTION= option in the MODEL statement. See the section “Weight Functions” on page 3995 for a complete discussion. You can specify the scale parameter \( \sigma \) with the SCALE= option in the PROC statement.

If \( \sigma \) is unknown, both \( \theta \) and \( \sigma \) are estimated by minimizing the function

\[
Q(\theta, \sigma) = \sum_{i=1}^{n} [\rho\left(\frac{r_i}{\sigma}\right) + a]\sigma, \ a > 0
\]

The algorithm proceeds by alternately improving \( \hat{\theta} \) in a location step and \( \hat{\sigma} \) in a scale step.

For the scale step, three methods are available to estimate \( \sigma \), which you can select with the SCALE= option.
1. (SCALE=HUBER<(D=d)>) Compute $\hat{\sigma}$ by the iteration

$$(\hat{\sigma}^{(m+1)})^2 = \frac{1}{nh} \sum_{i=1}^{n} \chi_d\left(\frac{r_i}{\hat{\sigma}^{(m)}}\right)(\hat{\sigma}^{(m)})^2$$

where

$$\chi_d(x) = \begin{cases} 
  x^2/2 & \text{if } |x| < d \\
  d^2/2 & \text{otherwise}
\end{cases}$$

is the Huber function and

$$h = \frac{n-p}{n}d^2 + (1-d^2)\Phi(d) - 0.5 - d\sqrt{2\pi e^{-1/2}}$$

is the Huber constant (refer to Huber 1981, p. 179). You can specify $d$ with the D= option. By default, $d = 2.5$.

2. (SCALE=TUKEY<(D=d)>) Compute $\hat{\sigma}$ by solving the supplementary equation

$$\frac{1}{n-p} \sum_{i=1}^{n} \chi_d\left(\frac{r_i}{\sigma}\right) = \beta$$

where

$$\chi_d(x) = \begin{cases} 
  \frac{3x^2}{d^2} - \frac{3x^4}{d^4} + \frac{2x^6}{d^6} & \text{if } |x| < d \\
  \text{otherwise}
\end{cases}$$

Here $\psi = \frac{1}{6}\chi_1'$ is Tukey’s biweight function, and $\beta = \int \chi_d(s) d\Phi(s)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (refer to Hampel et. al. 1986, p. 149). You can specify $d$ with the D= option. By default, $d = 2.5$.

3. (SCALE=MED) Compute $\hat{\sigma}$ by the iteration

$$\hat{\sigma}^{(m+1)} = \text{median}\{|y_i - x_i^T \hat{\theta}^{(m)}|/\beta_0, i = 1, \ldots, n\}$$

where $\beta_0 = \Phi^{-1}(0.75)$ is the constant such that the solution $\hat{\sigma}$ is asymptotically consistent when $L(\cdot/\sigma) = \Phi(\cdot)$ (refer to Hampel et. al. 1986, p. 312).

Note that SCALE = MED is the default.

**Algorithm**

The basic algorithm for computing M estimates for regression is iteratively reweighted least squares (IRLS). As the name suggests, a weighted least squares fit is carried out inside an iteration loop. For each iteration, a set of weights for the observations is used in the least squares fit. The weights are constructed by applying a weight function to the current residuals. Initial weights are based on residuals from an initial fit. The ROBUSTREG procedure uses the unweighted least squares fit as a default initial fit. The iteration terminates when a convergence criterion is satisfied. The maximum number of iterations is set to 1000. You can specify the weight function and the convergence criteria.
You can specify the weight function for M estimation with the WEIGHTFUNCTION= option. The ROBUSTREG procedure provides ten weight functions. By default, the procedure uses the bisquare weight function. In most cases, M estimates are more sensitive to the parameters of these weight functions than to the type of the weight function. The median weight function is not stable and is seldom recommended in data analysis; it is included in the procedure for completeness. You can specify the parameters for these weight functions. Except for the hampel and median weight functions, default values for these parameters are defined such that the corresponding M estimates have 95% asymptotic efficiency in the location model with the Gaussian distribution (see Holland and Welsch (1977)).

The following list shows the weight functions available.

- **andrews**
  \[
  W(x, c) = \begin{cases} 
  \frac{\sin(x/c)}{x} & \text{if } |x| \leq \pi c \\
  0 & \text{otherwise}
  \end{cases}
  \]

- **bisquare**
  \[
  W(x, c) = \begin{cases} 
  (1 - (x/c)^2)^2 & \text{if } |x| < c \\
  0 & \text{otherwise}
  \end{cases}
  \]

- **cauchy**
  \[
  W(x, c) = \frac{1}{1 + (x/c)^2}
  \]

- **fair**
  \[
  W(x, c) = \frac{1}{(1 + (x/c)^2)}
  \]
hampel \( W(x, a, b, c) = \begin{cases} 
\frac{1}{|x|} & |x| < a \\
\frac{a}{|x|} & a < |x| \leq b \\
\frac{a}{|x|} e^{-|x|} & b < |x| \leq c \\
0 & \text{otherwise}
\end{cases} \)

huber \( W(x, c) = \begin{cases} 
1 & |x| < c \\
\frac{c}{|x|} & \text{otherwise}
\end{cases} \)

logistic \( W(x, c) = \frac{\tanh\left(\frac{x}{c}\right)}{c} \)

median \( W(x, c) = \begin{cases} 
\frac{1}{|x|} & x = 0 \\
1 & |x| \text{ otherwise}
\end{cases} \)

talworth \( W(x, c) = \begin{cases} 
1 & |x| < c \\
0 & \text{otherwise}
\end{cases} \)
M Estimation

```
welsch \[ W(x, c) = \exp(-\frac{1}{2}(\frac{x}{c})^2) \]
```

See Table 62.4 on page 3985 for the default values of the constants in these weight functions.

**Convergence Criteria**

The following convergence criteria are available in PROC ROBUSTREG:

1. Relative change in the scaled residuals (CONVERGENCE= RESID)
2. Relative change in the coefficients (CONVERGENCE= COEF)
3. Relative change in weights (CONVERGENCE= W)

You can specify the criteria with the CONVERGENCE= option in the PROC statement. The default is CONVERGENCE= COEF.

You can specify the precision of the convergence criterion with the EPS= sub-option.

In addition to these convergence criteria, a convergence criterion based on scale-independent measure of the gradient is always checked. See Coleman, et. al. (1980). A warning is issued if this criterion is not satisfied.

**Asymptotic Covariance and Confidence Intervals**

The following three estimators of the asymptotic covariance of the robust estimator are available in PROC ROBUSTREG:

\[ H1: K^2 \frac{1/(n-p)}{\left( \frac{1}{n} \sum (\psi'(r_i))^2 \right) \sum (\psi'(r_i))^2 (X^T X)^{-1}} \]

\[ H2: K \frac{1/(n-p)}{\left( \frac{1}{n} \sum (\psi'(r_i))^2 \right) W^{-1}} \]

\[ H3: K^{-1} \frac{1}{n-p} \sum (\psi'(r_i))^2 W^{-1} (X^T X) W^{-1} \]

where \( K = 1 + \frac{p \text{ var}(\psi')}{n(\text{E}\psi')^2} \) is a correction factor and \( W_{jk} = \sum \psi'(r_i)x_{ij}x_{ik} \). Refer to Huber (1981, p. 173) for more details.
You can specify the asymptotic covariance estimate with the option ASYMPCOV= option. The ROBUSTREG procedure uses H1 as the default because of its simplicity and stability. Confidence intervals are computed from the diagonal elements of the estimated asymptotic covariance matrix.

\section*{\textit{R}^2 \text{ and Deviance}}

The robust version of $R^2$ is defined as

$$R^2 = \frac{\sum \rho\left(\frac{y_i - \hat{\mu}}{s}\right) - \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{s}\right)}{\sum \rho\left(\frac{y_i - \hat{\mu}}{s}\right)}$$

and the robust deviance is defined as the optimal value of the objective function on the $\sigma^2$-scale:

$$D = 2(\hat{s})^2 \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{\hat{s}}\right)$$

where $\rho' = \psi$, $\hat{\theta}$ is the M estimator of $\theta$, $\hat{\mu}$ is the M estimator of location, and $\hat{s}$ is the M estimator of the scale parameter in the full model.

\section*{Linear Tests}

Two tests are available in PROC ROBUSTREG for the canonical linear hypothesis

$$\mathcal{H}_0 : \theta_j = 0, \ j = q + 1, \ldots, p$$

The first test is a robust version of the F test, which is referred to as the $\rho$-test. Denote the M estimators in the full and reduced model as $\hat{\theta}_0 \in \Omega_0$ and $\hat{\theta}_1 \in \Omega_1$, respectively. Let

$$Q_0 = Q(\hat{\theta}_0) = \min\{Q(\theta)|\theta \in \Omega_0\}$$

$$Q_1 = Q(\hat{\theta}_1) = \min\{Q(\theta)|\theta \in \Omega_1\}$$

with

$$Q = \sum_{i=1}^{n} \rho\left(\frac{r_i}{\sigma}\right)$$

The robust F test is based on the test statistic

$$S_n^2 = \frac{2}{p - q} [Q_1 - Q_0]$$
Asymptotically $S_n^2 \sim \lambda \chi^2_{p-q}$ under $\mathcal{H}_0$, where the standardization factor is $\lambda = \int \psi^2(s) d\Phi(s) / \int \psi'(s) d\Phi(s)$ and $\Phi$ is the cumulative distribution function of the standard normal distribution. Large values of $S_n^2$ are significant. This test is a special case of the general $\tau$-test of Hampel et al. (1986, Section 7.2).

The second test is a robust version of the Wald test, which is referred to as $R_n^2$-test. The test uses a test statistic

$$R_n^2 = n(\hat{\theta}_{q+1}, \ldots, \hat{\theta}_p) H_{22}^{-1}(\hat{\theta}_{q+1}, \ldots, \hat{\theta}_p)^T$$

where $\frac{1}{n} H_{22}$ is the $(p - q) \times (p - q)$ lower right block of the asymptotic covariance matrix of the M estimate $\hat{\theta}_M$ of $\theta$ in a $p$-parameter linear model.

Under $\mathcal{H}_0$, the statistic $R_n^2$ has an asymptotic $\chi^2$ distribution with $p - q$ degrees of freedom. Large absolute values of $R_n^2$ are significant. Refer to Hampel et al. (1986, Chapter 7).

**Model Selection**

When M estimation is used, two criteria are available in PROC ROBUSTREG for model selection. The first criterion is a counterpart of the Akaike (1974) AIC criterion for robust regression, and it is defined as

$$AICR = 2 \sum_{i=1}^{n} \rho(r_{i;p}) + \alpha p$$

where $r_{i;p} = (y_i - x_i^T \hat{\theta}) / \hat{\sigma}$, $\hat{\sigma}$ is a robust estimate of $\sigma$ and $\hat{\theta}$ is the M estimator with $p$-dimensional design matrix.

As with AIC, $\alpha$ is the weight of the penalty for dimensions. The ROBUSTREG procedure uses $\alpha = 2E\psi^2 / E\psi'$ (Ronchetti (1985)) and estimates it using the final robust residuals.

The second criterion is a robust version of the Schwarz information criteria (BIC), and it is defined as

$$BICR = 2 \sum_{i=1}^{n} \rho(r_{i;p}) + p \log(n)$$

**High Breakdown Value Estimation**

The *breakdown value* of an estimator is defined as the smallest fraction of contamination that can cause the estimator to take on values arbitrarily far from its value on the uncontaminated data. The breakdown value of an estimator can be used as a measure of the robustness of the estimator. Rousseeuw and Leroy (1987) and others introduced the following high breakdown value estimators for linear regression.
LTS Estimate

The least trimmed squares (LTS) estimate proposed by Rousseeuw (1984) is defined as the $p$-vector

$$\hat{\theta}_{LTS} = \arg \min_{\theta} Q_{LTS}(\theta)$$

where

$$Q_{LTS}(\theta) = \sum_{i=1}^{h} r_{(i)}^2$$

$r_{(1)}^2 \leq r_{(2)}^2 \leq \ldots \leq r_{(n)}^2$ are the ordered squared residuals $r_i^2 = (y_i - x_i^T \theta)^2$, $i = 1, \ldots, n$, and $h$ is defined in the range $n^2 + 1 \leq h \leq \frac{3n+p+1}{4}$.

You can specify the parameter $h$ with the H= option in the PROC statement. By default, $h = \lceil \frac{3n+p+1}{4} \rceil$. The breakdown value is $\frac{n-h}{n}$ for the LTS estimate.

The least median of squares (LMS) estimate is defined as the $p$-vector

$$\hat{\theta}_{LMS} = \arg \min_{\theta} Q_{LMS}(\theta)$$

where

$$Q_{LMS}(\theta) = r_{(h)}^2$$

$r_{(1)}^2 \leq r_{(2)}^2 \leq \ldots \leq r_{(n)}^2$ are the ordered squared residuals $r_i^2 = (y_i - x_i^T \theta)^2$, $i = 1, \ldots, n$, and $h$ is defined in the range $n^2 + 1 \leq h \leq \frac{3n+p+1}{4}$.

The breakdown value for the LMS estimate is also $\frac{n-h}{n}$. However the LTS estimate has several advantages over the LMS estimate. Its objective function is smoother, making the LTS estimate less “jumpy” (i.e. sensitive to local effects) than the LMS estimate. Its statistical efficiency is better, because the LTS estimate is asymptotically normal whereas the LMS estimate has a lower convergence rate (Rousseeuw and Leroy (1987)). Another important advantage is that, using the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000), the LTS estimate takes less computing time and is more accurate.

The ROBUSTREG procedure computes LTS estimates using the FAST-LTS algorithm. The estimates are often used to detect outliers in the data, which are then downweighted in the resulting weighted LS regression.
Algorithm

Least trimmed squares (LTS) regression is based on the subset of \( h \) observations (out of a total of \( n \) observations) whose least squares fit possesses the smallest sum of squared residuals. The coverage \( h \) may be set between \( \frac{2}{n} \) and \( n \). The LTS method was proposed by Rousseeuw (1984, p. 876) as a highly robust regression estimator with breakdown value \( \frac{n-h}{n} \). The ROBUSTREG procedure uses the FAST-LTS algorithm given by Rousseeuw and Van Driessen (1998). The intercept adjustment technique is also used in this implementation. However, because this adjustment is expensive to compute, it is optional. You can use the IADJUST option in the PROC statement to request or suppress the intercept adjustment. By default, PROC ROBUSTREG does intercept adjustment for data sets with less than 10000 observations. The algorithm is described briefly as follows. Refer to Rousseeuw and Van Driessen (2000) for details.

1. The default \( h \) is \( \left\lfloor \frac{3n+p+1}{4} \right\rfloor \), where \( p \) is the number of independent variables. You can specify any integer \( h \) with \( \left\lfloor \frac{n}{2} \right\rfloor + 1 \leq h \leq \left\lfloor \frac{3n+p+1}{4} \right\rfloor \) with the \texttt{H=} option in the MODEL statement. The breakdown value for LTS, \( \frac{n-h}{n} \), is reported. The default \( h \) is a good compromise between breakdown value and statistical efficiency.

2. If \( p = 1 \) (single regressor) the procedure uses the exact algorithm of Rousseeuw and Leroy (1987, p. 172-172).

3. If \( p \geq 2 \), the procedure uses the following algorithm. If \( n < 2ssubs \), where \( ssubs \) is the size of the subgroups (you can specify \( ssubs \) using the \texttt{SUBGROUPSIZE=} option in the PROC statement, by default, \( ssubs = 300 \)), draw a random \( p \)-subset and compute the regression coefficients using these \( p \) points (if the regression is degenerate, draw another \( p \)-subset). Compute the absolute residuals for all observations in the data set and select the first \( h \) points with smallest absolute residuals. From this selected \( h \)-subset, carry out \( nsteps \) C-steps (Concentration step, see Rousseeuw and Van Driessen (2000) for details. You can specify \( nsteps \) with the \texttt{CSTEP=} option in the PROC statement, by default, \( nsteps = 2 \)). Redraw \( p \)-subsets and repeat the preceding computing procedure \( nrep \) times and find the \( nsol \) (at most) solutions with the lowest sums of \( h \) squared residuals. \( nrep \) can be specified with the \texttt{NREP=} option in the PROC statement. By default, \( \texttt{NREP=}\min\{500,\binom{n}{p}\} \}. For small \( n \) and \( p \), all \( \binom{n}{p} \) subsets are used and the \texttt{NREP=} option is ignored (Rousseeuw and Hubert (1996)). \( nsol \) can be specified with the \texttt{NBEST=} option in the PROC statement. By default, \( \texttt{NBEST=10} \). For each of these \( nsol \) best solutions, take C-steps until convergence and find the best final solution.

4. If \( n \geq 5ssubs \), construct 5 disjoint random subgroups with size \( ssubs \). If \( 2ssubs < n < 5ssubs \), the data are split into at most four subgroups with \( ssubs \) or more observations in each subgroup, so that each observation belongs to a subgroup and such that the subgroups have roughly the same size. Let \( nsubs \) denote the number of subgroups. Inside each subgroup, repeat the procedure in Step 3 \( \left\lfloor \frac{nrep}{nsubs} \right\rfloor \) times and keep the \( nsol \) best solutions. Pool the subgroups, yielding the merged set of size \( n_{merged} \). In the merged set, for each of the \( nsubs \times nsol \) best solutions, carry out \( nsteps \) C-steps using \( n_{merged} \) and \( h_{merged} = \left\lfloor \frac{n_{merged}}{n} \right\rfloor \) and keep the \( nsol \) best solutions. In the full data set, for
each of these \( n_{bsol} \) best solutions, take \( C \)-steps using \( n \) and \( h \) until convergence and find the best final solution.

\( R^2 \)

The robust version of \( R^2 \) for the LTS estimate is defined as

\[
R_{LTS}^2 = 1 - \frac{s_{LTS}^2(X, y)}{s_{LTS}^2(1, y)}
\]

for models with the intercept term and as

\[
R_{LTS}^2 = 1 - \frac{s_{LTS}^2(X, y)}{s_{LTS}^2(0, y)}
\]

for models without the intercept term, where

\[
s_{LTS}(X, y) = d_{h,n} \sqrt{\frac{1}{h} \sum_{i=1}^{h} r_i^2(i)}
\]

\( s_{LTS} \) is a preliminary estimate of the parameter \( \sigma \) in the distribution function \( L(\cdot / \sigma) \).

Here \( d_{h,n} \) is chosen to make \( s_{LTS} \) consistent assuming a Gaussian model. Specifically,

\[
d_{h,n} = \frac{1}{\sqrt{1 - \frac{2n}{h c_{h,n}} \phi(1/c_{h,n})}}
\]

\[
c_{h,n} = \frac{1}{\Phi^{-1}\left(\frac{h + n}{2n}\right)}
\]

with \( \Phi \) and \( \phi \) being the distribution function and the density function of the standard normal distribution, respectively.

**Final Weighted Scale Estimator**

The ROBUSTREG procedure displays two scale estimators, \( s_{LTS} \) and \( W_{scale} \). The estimate \( W_{scale} \) is a more efficient scale estimate based on the preliminary estimate \( s_{LTS} \), and it is defined as

\[
W_{scale} = \sqrt{\frac{\sum_i w_i r_i^2}{\sum_i w_i - p}}
\]

where

\[
w_i = \begin{cases} 
0 & \text{if } |r_i|/s_{LTS} > k \\
1 & \text{otherwise}
\end{cases}
\]

You can specify \( k \) with the CUTOFF= option in the MODEL statement. By default, \( k = 3 \).
**S Estimate**

The S estimate proposed by Rousseeuw and Yohai (1984) is defined as the $p$-vector

$$\hat{\theta}_S = \arg \min_\theta S(\theta)$$

where the dispersion $S(\theta)$ is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi \left( \frac{y_i - x_i^T \theta}{S} \right) = \beta.$$  

Here $\beta$ is set to $\int \chi(s)d\Phi(s)$ such that $\hat{\theta}_S$ and $S(\hat{\theta}_S)$ are asymptotically consistent estimates of $\theta$ and $\sigma$ for the Gaussian regression model. The breakdown value of the S estimate is

$$\frac{\beta}{\sup_s \chi(s)}$$

The ROBUSTREG procedure provides two choices for $\chi$: the Tukey function and the Yohai function.

The Tukey function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 
3 \left( \frac{s}{k_0} \right)^2 - 3 \left( \frac{s}{k_0} \right)^4 + \left( \frac{s}{k_0} \right)^6, & \text{if } |s| \leq k_0 \\
1 & \text{otherwise}
\end{cases}$$

The constant $k_0$ controls the breakdown value and efficiency of the S estimate. By specifying the efficiency using the EFF= option, you can determine the corresponding $k_0$. The default $k_0$ is 2.9366 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 75.9%.

The Yohai function, which you can specify with the option CHIF=YOHAI, is

$$\chi_{k_0}(s) = \begin{cases} 
\frac{s^2}{2k_0^2} \left[ b_0 + b_1 \left( \frac{s}{k_0} \right)^2 + b_2 \left( \frac{s}{k_0} \right)^4 + b_3 \left( \frac{s}{k_0} \right)^6 + b_4 \left( \frac{s}{k_0} \right)^8 \right], & \text{if } 2k_0 < |s| \leq 3k_0 \\
3.25k_0 \left[ b_0 + b_1 \left( \frac{s}{k_0} \right)^2 + b_2 \left( \frac{s}{k_0} \right)^4 + b_3 \left( \frac{s}{k_0} \right)^6 + b_4 \left( \frac{s}{k_0} \right)^8 \right], & \text{if } |s| > 3k_0
\end{cases}$$

where $b_0 = 1.792, b_1 = -0.972, b_2 = 0.432, b_3 = -0.052$, and $b_4 = 0.002$. By specifying the efficiency using the EFF= option, you can determine the corresponding $k_0$. By default, $k_0$ is set to 0.7405 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 72.7%.
Algorithm

The ROBUSTREG procedure implements the algorithm by Marazzi (1993) for the S estimate, which is a refined version of the algorithm proposed by Ruppert (1992). The refined algorithm is briefly described as follows.

Initialize \( \text{iter} = 1 \).

1. Draw a random \( q \)-subset of the total \( n \) observations and compute the regression coefficients using these \( q \) observations (if the regression is degenerate, draw another \( q \)-subset), where \( q \geq p \) can be specified with the SUBSIZE= option. By default, \( q = p \).

2. Compute the residuals: \( r_i = y_i - \sum_{j=1}^{p} x_{ij} \theta_j \) for \( i = 1, \ldots, n \). If \( \text{iter} = 1 \), set \( s^* = 2 \text{median}\{|r_i|, i = 1, \ldots, n\} \); if \( s^* = 0 \), set \( s^* = \min\{|r_i|, i = 1, \ldots, n\} \); while \( \sum_{i=1}^{n} \chi(r_i/s^*) > (n - p)/\beta \), set \( s^* = 1.5s^* \); go to Step 3.

   If \( \text{iter} > 1 \) and \( \sum_{i=1}^{n} \chi(r_i/s^*) \leq (n - p)/\beta \), go to the Step 3; else go to Step 5.

3. Solve for \( s \) the equation
   \[
   \frac{1}{n - p} \sum_{i=1}^{n} \chi(r_i/s) = \beta
   \]
   using an iterative algorithm.

4. If \( \text{iter} > 1 \) and \( s > s^* \), go to Step 5. Otherwise, set \( s^* = s \) and \( \theta^* = \theta \). If \( s^* < TOLS \), return \( s^* \) and \( \theta^* \); else go to Step 5.

5. if \( \text{iter} < NREP \), set \( \text{iter} = \text{iter} + 1 \) and return to Step 1; else return \( s^* \) and \( \theta^* \).

The ROBUSTREG procedure does the following refinement step by default. You can request this refinement not be done using the NOREFINE option in the PROC statement.

6. Let \( \psi = \chi' \). Using the values \( s^* \) and \( \theta^* \) from the previous steps, compute M estimates \( \hat{\theta}_M \) and \( \hat{\sigma}_M \) of \( \theta \) and \( \sigma \) with the setup for M estimation in the section “M Estimation” on page 3993. If \( \sigma_M > s^* \), give a warning and return \( s^* \) and \( \theta^* \); otherwise, return \( \sigma_M \) and \( \theta_M \).

You can specify \( TOLS \) with the TOLERANCE= option; by default, \( TOLS = .001 \). Alternately you can specify \( NREP \) with the NREP= option. You can also use the options NREP= NREP0 or NREP= NREP1 to determine \( NREP \) according to the following table. NREP= NREP0 is set as the default.
Table 62.7. Default NREP

\[ R^2_S = 1 - \frac{(n - p)S_p^2}{(n - 1)S_\mu^2} \]

for the model with the intercept term and

\[ R^2_S = 1 - \frac{(n - p)S_p^2}{nS_0^2} \]

for the model without the intercept term, where \( S_p \) is the S estimate of the scale in the full model, \( S_\mu \) is the S estimate of the scale in the regression model with only the intercept term, and \( S_0 \) is the S estimate of the scale without any regressor. The deviance \( D \) is defined as the optimal value of the objective function on the \( \sigma^2 \)-scale:

\[ D = S_p^2 \]

Asymptotic Covariance and Confidence Intervals

Since the S estimate satisfies the first-order necessary conditions as the M estimate, it has the same asymptotic covariance as that of the M estimate. All three estimators of the asymptotic covariance for the M estimate in the section “Asymptotic Covariance and Confidence Intervals” on page 3997 can be used for the S estimate. Besides, the weighted covariance estimator H4 described in the section “Asymptotic Covariance and Confidence Intervals” on page 4008 is also available and is set as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.
MM Estimation

MM estimation is a combination of high breakdown value estimation and efficient estimation, which was introduced by Yohai (1987). It has three steps:

1. Compute an initial (consistent) high breakdown value estimate \( \hat{\theta}' \). The ROBUSTREG procedure provides two kinds of estimates as the initial estimate, the LTS estimate and the S estimate. By default, the LTS estimate because of its speed, efficiency, and high breakdown value. The breakdown value of the final MM estimate is decided by the breakdown value of the initial LTS estimate and the constant \( k_0 \) in the \( \chi \) function. To use the S estimate as the initial estimate, you specify the INITEST=S option in the PROC statement. In this case, the breakdown value of the final MM estimate is decided only by the constant \( k_0 \). Instead of computing the LTS estimate or the S estimate as initial estimates, you can also specify the initial estimate explicitly using the INEST= option in the PROC statement. See the section “INEST= Data Set” on page 4011 for details.

2. Find \( \hat{\sigma}' \) such that

\[
\frac{1}{n - p} \sum_{i=1}^{n} \chi\left( \frac{y_i - x_i^T \hat{\theta}'}{\hat{\sigma}'} \right) = \beta
\]

where \( \beta = \int \chi(s) d\Phi(s) \).

The ROBUSTREG procedure provides two choices for \( \chi \): the Tukey function and the Yohai function.

The Tukey function, which you can specify with the option CHIF=TUKEY, is

\[
\chi_{k_0}(s) = \begin{cases} 
3\left( \frac{s}{k_0} \right)^2 - 3\left( \frac{s}{k_0} \right)^4 + \left( \frac{s}{k_0} \right)^6, & \text{if } |s| \leq k_0 \\
1 & \text{otherwise}
\end{cases}
\]

where \( k_0 \) can be specified with the K0= option. The default \( k_0 = 2.9366 \) such that the asymptotically consistent scale estimate \( \hat{\sigma}' \) has the breakdown value of 25%.

The Yohai function, which you can specify with the option CHIF=YOHAI, is

\[
\chi_{k_0}(s) = \begin{cases} 
\frac{s^2}{\sqrt{7}} & \text{if } |s| \leq 2k_0 \\
k_0^2 [b_0 + b_1 \left( \frac{s}{k_0} \right)^2 + b_2 \left( \frac{s}{k_0} \right)^4 + b_3 \left( \frac{s}{k_0} \right)^6 + b_4 \left( \frac{s}{k_0} \right)^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\
3.25k_0^2 & \text{if } |s| > 3k_0
\end{cases}
\]

where \( b_0 = 1.792, b_1 = -0.972, b_2 = 0.432, b_3 = -0.052, \) and \( b_4 = 0.002 \).

You can specify \( k_0 \) with the K0= option. The default \( k_0 = 0.7405 \) such that the asymptotically consistent scale estimate \( \hat{\sigma}' \) has the breakdown value of 25%.
3. Find a local minimum $\hat{\theta}_{MM}$ of

$$Q_{MM} = \sum_{i=1}^{n} \rho(y_i - x_i^T \hat{\theta} / \hat{\sigma}')$$

such that $Q_{MM}(\hat{\theta}_{MM}) \leq Q_{MM}(\hat{\theta}')$. The algorithm for M estimation is used here.

The ROBUSTREG procedure provides two choices for $\chi$: the Tukey function and the Yohai function.

The Tukey function, which you can specify with the option CHIF=TUKEY, is

$$\rho(s) = \begin{cases} \frac{3s}{k_1^2} - \frac{3s}{k_1^4} + \left(\frac{s}{k_1}\right)^6, & \text{if } |s| \leq k_1 \\ \frac{3}{k_1^2}, & \text{otherwise} \end{cases}$$

where $k_1$ can be specified with the K1= option. The default $k_1$ is 3.440 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

The Yohai function, which you can specify with the option CHIF=Yohai, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_1 \\ k_1^2 [b_0 + b_1 (\frac{s}{k_1})^2 + b_2 (\frac{s}{k_1})^4 + b_3 (\frac{s}{k_1})^6 + b_4 (\frac{s}{k_1})^8] & \text{if } 2k_1 < |s| \leq 3k_1 \\ 3.25 k_1^2 & \text{if } |s| > 3k_1 \end{cases}$$

where $k_1$ can be specified with the K1= option. The default $k_1$ is 0.868 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

**Algorithm**

The initial LTS estimate is computed using the algorithm described in the section “LTS Estimate” on page 4000. You can control the quantile of the LTS estimate with the option INITH=h, where $h$ is an integer between $\left\lceil \frac{n}{2} \right\rceil + 1$ and $\left\lceil \frac{3n + p + 1}{4} \right\rceil$. By default, $h = \left\lceil \frac{3n + p + 1}{4} \right\rceil$, which corresponds to a breakdown value of around 25%.

The initial S estimate is computed using the algorithm described in the section “S Estimate” on page 4003. You can control the breakdown value and efficiency of this initial S estimate by the constant $k_0$ which can be specified with the K0 option.

The scale parameter $\sigma$ is solved by an iterative algorithm

$$(\sigma^{(m+1)})^2 = \frac{1}{(n-p)\beta} \sum_{i=1}^{n} \chi_{k_0}(r_i / \sigma^{(m)}) (\sigma^{(m)})^2$$

where $\beta = \int \chi_{k_0}(s) d\Phi(s)$.

Once the scale parameter is computed, the iteratively reweighted least squares (IRLS) algorithm with fixed scale parameter is used to compute the final MM estimator.
Convergence Criteria

In the iterative algorithm for the scale parameter, the relative change of the scale parameter controls the convergence.

In the iteratively reweighted least squares algorithm, the same convergence criteria for the M estimate used before are used here.

Bias Test

Although the final MM estimate inherits the high-breakdown-value property, its bias due to the distortion of the outliers can be high. Yohai, Stahel, and Zamar (1991) introduced a bias test. The ROBUSTREG procedure implements this test when you specify the BIASTEST option in the PROC statement. This test bases on the initial scale estimate \( \hat{\sigma}' \) and the final scale estimate \( \hat{\sigma}'_1 \), which is the solution of

\[
\frac{1}{n - p} \sum_{i=1}^{n} \chi \left( \frac{y_i - x_i^T \hat{\theta}_{MM}}{\hat{\sigma}'_1} \right) = \beta
\]

Let \( \psi_{k_0}(\cdot) = \chi'_{k_0}(\cdot) \) and \( \psi_{k_1}(\cdot) = \chi'_{k_1}(\cdot) \), where \( \cdot' \) denotes the derivative with respect to the argument. Compute

\[
\tilde{r}_i = \frac{(y_i - x_i^T \hat{\theta}')}{\hat{\sigma}'} \quad \text{for } i = 1, ..., n
\]

\[
v_0 = \frac{1}{(\hat{\sigma}'_1/n)} \sum \psi'_{k_0}(\tilde{r}_i) \tilde{r}_i
\]

\[
p_i^{(0)} = \frac{\psi_{k_0}(\tilde{r}_i)}{1/n} \sum \psi'_{k_0}(\tilde{r}_i) \quad \text{for } i = 1, ..., n
\]

\[
p_i^{(1)} = \frac{\psi_{k_1}(\tilde{r}_i)}{1/n} \sum \psi'_{k_1}(\tilde{r}_i) \quad \text{for } i = 1, ..., n
\]

\[
d^2 = \frac{1}{n} \sum (p_i^{(1)} - p_i^{(0)})^2
\]

\[
T = \frac{2n(\hat{\sigma}'_1 - \hat{\sigma}')}{{v_0 d^2}(\hat{\sigma}')^2}
\]

Standard asymptotic theory shows that \( T \) approximately follows a \( \chi^2 \)-distribution with \( p \) degrees of freedom. If \( T \) exceeds the \( \alpha \) quantile \( \chi^2_\alpha \) of the \( \chi^2 \)-distribution with \( p \) degrees of freedom, then the ROBUSTREG procedure gives a warning and recommends to use other methods. Otherwise the final MM estimate and the initial scale estimate are reported. You can specify \( \alpha \) with the ALPHA= option following the BIASTEST option. By default, ALPHA= 0.99.

Asymptotic Covariance and Confidence Intervals

Since the MM estimate is computed as a M estimate with a fixed scale in the last step, the asymptotic covariance for the M estimate can be used here for the asymptotic covariance of the MM estimate. Besides the three estimators H1, H2, and H3 as
described in the section “Asymptotic Covariance and Confidence Intervals” on page 3997, a weighted covariance estimator H4 is available:

$$H4: K^2 \frac{1}{(1/n) \sum (\psi'(r_i))^2} W^{-1}$$

where $K = 1 + \frac{p \text{var}(\psi')}{n} \frac{(E\psi')^2}{\sum w_i}$ is the correction factor and $W_{jk} = \frac{1}{\bar{w}} \sum w_i x_{ij} x_{ik}$, $\bar{w} = \frac{1}{n} \sum w_i$.

You can specify these estimators with the option ASYMPCOV=[H1 | H2 | H3 | H4]. The ROBUSTREG procedure uses H4 as default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

**$R^2$ and Deviance**

The robust version of $R^2$ for the MM estimate is defined as

$$R^2 = \frac{\sum \rho\left(\frac{y_i - \hat{\mu}}{s}\right) - \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{s}\right)}{\sum \rho\left(\frac{y_i - \hat{\mu}}{s}\right)}$$

and the robust deviance is defined as the optimal value of the objective function on the $\sigma^2$-scale:

$$D = 2 \hat{s}^2 \sum \rho\left(\frac{y_i - x_i^T \hat{\theta}}{\hat{s}}\right)$$

where $\rho' = \psi$, $\hat{\theta}$ is the MM estimator of $\theta$, $\hat{\mu}$ is the MM estimator of location, and $\hat{s}$ is the MM estimator of the scale parameter in the full model.

**Linear Tests**

For MM estimation, the same $\rho$-test and $R^2_n$-test used for M estimation can be used. See the section “Linear Tests” on page 3998 for details.

**Model Selection**

For MM estimation, the same two model selection methods used for M estimation can be used. See the section “Model Selection” on page 3999 for details.

**Robust Multivariate Location and Scale Estimates**

The ROBUSTREG procedure uses the robust multivariate location and scale estimates for leverage points detection. The procedure provides the minimum covariance determinant (MCD) method, which was introduced by Rousseeuw (1984).
Algorithm

PROC ROBUSTREG implements the algorithm given by Rousseeuw and Van Driessen (1999) for MCD, which is similar to the algorithm for LTS.

Robust Distance

The Mahalanobis Distance is defined as
\[ MD(x_i) = [(x_i - \bar{x})^T \bar{C}(X)^{-1} (x_i - \bar{x})]^{1/2} \]
where \( \bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \) and \( \bar{C} = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^T (x_i - \bar{x}) \). Here \( x_i = (x_{i1}, ..., x_{i(p-1)})^T \) do not include the constant variable. The relation between the Mahalanobis distance \( MD(x_i) \) and the hat matrix \( H = (h_{ij}) = X(X^T X)^{-1} X^T \) is
\[ h_{ii} = \frac{1}{n-1} MD_i^2 + \frac{1}{n} \]

The Robust Distance is defined as
\[ RD(x_i) = [(x_i - T(X))^T C(X)^{-1} (x_i - T(X))]^{1/2} \]
where \( T(X) \) and \( C(X) \) are the robust multivariate location and scale obtained by MCD.

These distances are used to detect leverage points.

Leverage Point and Outlier Detection

Let \( C(p) = \sqrt{\chi^2_{p,1-\alpha}} \) be the cutoff value. The variable LEVERAGE is defined as
\[
\text{LEVERAGE} = \begin{cases} 
0 & \text{if } RD(x_i) \leq C(p) \\
1 & \text{otherwise}
\end{cases}
\]

You can specify a cutoff value with the LEVERAGE option in the MODEL statement.

Residuals \( r_i, i = 1, ..., n \) based on robust regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as
\[
\text{OUTLIER} = \begin{cases} 
0 & \text{if } |r_i| \leq k\sigma \\
1 & \text{otherwise}
\end{cases}
\]

You can specify the multiplier \( k \) of the cutoff value by using the CUTOFF= option in the MODEL statement.

An ODS table called DIAGNOSTICS contains these two variables.
**INEST= Data Set**

When you use the M or MM estimation, you can use the INEST= data set to specify initial estimates for all the parameters in the model. The INEST= option is ignored if you specify LTS or S estimation using the METHOD=LTS or METHOD=S option or if you specify the INITEST= option after the METHOD=MM option in the PROC statement. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in one BY group, the first one read is used for that BY group.

If the INEST= data set also contains the _TYPE_ variable, only observations with _TYPE_ value “PARMS” are used as starting values.

You can specify starting values for the iteratively reweighted least squares algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

**OUTEST= Data Set**

The OUTEST= data set contains parameter estimates for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different modeling using the ROBUSTREG procedure. If the COVOUT option is specified, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates. Note that, if the ROBUSTREG procedure does not converge, the parameter estimates are set to missing in the OUTEST= data set.

The OUTES= data set contains all variables specified in the MODEL statement and the BY statement. One observation consists of parameter values for the model with the dependent variable having the value -1. If the COVOUT option is specified, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

- **_MODEL_** a character variable containing the label of the MODEL statement, if present. Otherwise, the variable’s value is blank
- **_NAME_** a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates
- **_TYPE_** a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates
- **_METHOD_** a character variable of containing the type of estimation method, either M estimation, or LTS estimation, or S estimation, or MM estimation
a character variable containing the status of model fitting, either Converged, or Warning, or Failed

INTERCEPT a numeric variable containing the intercept parameter estimates and covariances

_SCALE_ a numeric variable containing the scale parameter estimates

Any BY variables specified are also added to the OUTEST= data set.

**Computational Resources**

The algorithms for the various different estimation methods need different amount of memory for working space. Let $p$ be the number of parameters estimated and $n$ be the number of observations used in the model estimation.

For M estimation, the minimum working space (in bytes) needed is

$$3n + 2p^2 + 30p$$

If sufficient space is available, the input data set is also kept in memory; otherwise, the input data set is reread for computing the iteratively reweighted least squares estimates and the execution time of the procedure increases substantially. For each reweighted least squares, $O(np^2 + p^3)$ multiplications and additions are required for computing the cross product matrix and its inverse. The $O(v)$ notation means that, for large values of the argument, $v$, $O(v)$ is approximately a constant times $v$.

Since the iteratively reweighted least squares algorithm converges very quickly (normally within less than 20 iterations), the computation of M estimates is fast.

LTS estimation is more expensive in computation. The minimum working space (in bytes) needed is

$$np + 12n + 4p^2 + 60p$$

The memory is mainly used to store the current data used by LTS for modeling. The LTS algorithm uses subsampling and spends much of its computing time on resampling and computing estimates for subsamples. Since it resamples if singularity is detected, it may take more time if the data set has serious singularities.

The MCD algorithm for high leverage point diagnostics is similar to the LTS algorithm.

**ODS Table Names**

The ROBUSTREG procedures assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.
### Table 62.8. ODS Tables Produced in PROC ROBUSTREG

### ODS Graphics (Experimental)

Graphical displays are important in robust regression and outlier detection. Two plots are particularly useful for revealing outliers and leverage points. The first is a scatter plot of the standardized robust residuals against the robust distances (RDPLT). The second is a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLT). See Figure 62.4 on page 3975 and Figure 62.5 on page 3975 for examples. In addition to these two plots, a histogram and a quantile-quantile plot of the standardized robust residuals are also helpful. See Figure 62.6 on page 3976 and Figure 62.7 on page 3976 for examples.

This section describes the use of ODS for creating these four plots with the ROBUSTREG procedure. These graphics are experimental in this release, meaning that both the graphical results and the syntax for specifying them are subject to change in a future release.
To request these plots you must specify the ODS GRAPHICS statement in addition to the PLOT= (or PLOTS=) option, which is described as follows. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

You can specify the PLOT= or PLOTS= option in the PROC statement to request one or more plots:

\[
\text{PLOT=} \text{keyword} \\
\text{PLOTS=} (\text{keyword-list})
\]

requests plots for robust regression. You can specify one or more of the following keywords:

Table 62.9. Options for Plots

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Plot</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDPLOT</td>
<td>Robust distance - Mahalanobis distance</td>
</tr>
<tr>
<td>RDPLOT</td>
<td>Standardized robust residual - Robust distance</td>
</tr>
<tr>
<td>RESHISTOGRAM</td>
<td>Histogram of standardized robust residuals</td>
</tr>
<tr>
<td>RESQQPLOT</td>
<td>Q-Q plot of standardized robust residuals</td>
</tr>
<tr>
<td>ALL</td>
<td>All plots</td>
</tr>
</tbody>
</table>

With the RDPLOT and DDPLOT options, you can label the points on the plots by specifying the LABEL= suboption immediately after the keyword:

\[
\text{PLOT=} \text{DDPLOT}< (\text{LABEL=} \text{label method}) > \\
\text{PLOT=} \text{RDPLOT}< (\text{LABEL=} \text{label method}) >
\]

You can specify one of the following label methods:

Table 62.10. Label Methods

<table>
<thead>
<tr>
<th>Value of LABEL=</th>
<th>Label Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>label all points</td>
</tr>
<tr>
<td>OUTLIER</td>
<td>label outliers</td>
</tr>
<tr>
<td>LEVERAGE</td>
<td>label leverage points</td>
</tr>
<tr>
<td>NONE</td>
<td>no labels</td>
</tr>
</tbody>
</table>

By default, the ROBUSTREG procedure labels both outliers and leverage points.

If you specify ID variables in the ID statement, the values of the first ID variable are used as labels; otherwise, observation numbers are used as labels.

The histogram is superimposed with a normal density curve and a kernel density curve.

**ODS Graph Names**

PROC ROBUSTREG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 62.11 on page 4015.
To request these graphs you must specify the ODS GRAPHICS statement in addition to the PLOT= (or PLOTS=) option described in Table 62.9 on page 4014. For more information on the ODS GRAPHICS statement, see Chapter 15, “Statistical Graphics Using ODS.”

Examples

Example 62.1. Comparison of Robust Estimates

This example illustrates differences in the performance of robust estimates available in the ROBUSTREG procedure.

The following statements generate 1000 random observations. The first 900 observations are from a linear model and the last 100 observations are significantly biased in the $y$-direction. In other words, ten percent of the observations are contaminated with outliers.

data a (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 900 then y=100 + e;
    else y=10 + 5*x1 + 3*x2 + .5 * e;
    output;
  end;
run;

proc reg data=a;
  model y = x1 x2;
run;

proc robustreg data=a method=m ;
  model y = x1 x2;
run;

proc robustreg data=a method=mm;
  model y = x1 x2;
run;

The tables of parameter estimates generated by the ROBUSTREG procedure using M estimation and MM estimation are shown in Output 62.1.2 and Output 62.1.3. For comparison, the ordinary least squares (OLS) estimates produced by the REG procedure are shown in Output 62.1.1. Both the M estimate and the MM estimate correctly estimate the regression coefficients for the underlying model (10, 5, and 3), but the OLS estimate does not.

The next statements demonstrate that if the percentage of contamination is increased to 40%, the M estimates and MM estimates with default options fail to pick up the underlying model. However, by tuning the constant c for the M estimate and the constants INITH and K0 for the MM estimate, you can increase the breakdown values of these estimates and capture the right model. Output 62.1.4 and Output 62.1.5 display these estimates.

When there are bad leverage points, the M estimates fail to pick up the underlying model no matter what constant $c$ you use. In this case, other estimates (LTS, S, and MM estimates) in PROC ROBUSTREG, which are robust to bad leverage points, will pick up the underlying model.

The following statements generate 1000 observations with 1% bad high leverage points.

```sas
data b (drop=i);
  do i=1 to 1000;
    x1=rannor(1234);
    x2=rannor(1234);
    e=rannor(1234);
    if i > 600 then y=100 + e;
    else y=10 + 5*x1 + 3*x2 + .5 * e;
    if i < 11 then x1=200 * rannor(1234);
    if i < 11 then x2=200 * rannor(1234);
    if i < 11 then y= 100*e;
    output;
  end;
run;

proc robustreg data=b method=s(k0=1.8);
  model y = x1 x2;
run;
proc robustreg data=b method=mm(inith=502 k0=1.8);
  model y = x1 x2;
run;
```

Output 62.1.6 displays the S estimates and Output 62.1.7 displays the MM estimates with initial LTS estimates.

Example 62.2. Robust ANOVA

The classical analysis of variance (ANOVA) technique based on least squares assumes that the underlying experimental errors are normally distributed. However, data often contain outliers due to recording or other errors. In other cases, extreme responses occur when control variables in the experiments are set to extremes. It is important to distinguish these extreme points and determine whether they are outliers or important extreme cases. You can use the ROBUSTREG procedure for robust analysis of variance based on M estimation. Typically, there are no high leverage points in a well-designed experiment, so M estimation is appropriate.

The following example shows how to use the ROBUSTREG procedure for robust ANOVA.

An experiment was carried out to study the effects of two successive treatments (T1, T2) on the recovery time of mice with certain diseases. Sixteen mice were randomly assigned into four groups for the four different combinations of the treatments. The recovery times (time) were recorded (in hours).

data recover;
   input id T1 $ T2 $ time;
datalines;
  1 0 0 20.2
  2 0 0 23.9
  3 0 0 21.9
  4 0 0 42.4
  5 1 0 27.2
  6 1 0 34.0
  7 1 0 27.4
  8 1 0 28.5
  9 0 1 25.9
 10 0 1 34.5
The following statements invoke the GLM procedure for a standard ANOVA.

```plaintext
proc glm data=recover;
  class T1 T2;
  model time = T1 T2 T1*T2;
run;
```

```

The scale parameter is 3.5346.
The reason for the difference between the traditional ANOVA and the robust ANOVA is explained by Output 62.2.5, which shows that the fourth observation is an outlier. Further investigation shows that the original value of 24.4 for the fourth observation was recorded incorrectly.

Output 62.2.6 displays the robust test results. The interaction between the two treatments is not significant. Output 62.2.7 displays the robust residuals and standardized robust residuals.
Example 62.3. Growth Study of De Long and Summers

Robust regression and outlier detection techniques have considerable applications to econometrics. The following example from Zaman, Rousseeuw, and Orhan (2001) shows how these techniques substantially improve the ordinary least squares (OLS) results for the growth study of De Long and Summers.

De Long and Summers (1991) studied the national growth of 61 countries from 1960 to 1985 using OLS.

The regression equation they used is:

\[ GDP = \beta_0 + \beta_1 LFG + \beta_2 GAP + \beta_3 EQP + \beta_4 NEQ + \epsilon, \]

where the response variable is the growth in gross domestic product per worker \((GDP)\) and the regressors are labor force growth \((LFG)\), relative GDP gap \((GAP)\), equipment investment \((EQP)\), and non-equipment investment \((NEQ)\).

The following statements invoke the REG procedure for the OLS analysis:

```plaintext
proc reg data=growth;
   model GDP = LFG GAP EQP NEQ ;
run;
```

Output 62.3.1. OLS Estimates

The OLS analysis of Output 62.3.1 indicates that \(GAP\) and \(EQP\) have a significant influence on \(GDP\) at the 5% level.
The following statements invoke the ROBUSTREG procedure with the default M estimation.

```plaintext
proc robustreg data=growth;
  model GDP = LFG GAP EQP NEQ / diagnostics leverage;
  output out=robout r=resid sr=stdres;
run;
```

Output 62.3.3 displays the M estimates. Besides GAP and EPQ, the robust analysis also indicates that NEQ is significant. This new finding is explained by Output 62.3.4, which shows that Zambia, the sixtieth country in the data, is an outlier. Output 62.3.4 also identifies leverage points based the robust MCD distances; however, there are no serious high leverage points in this data set. Output 62.3.5 displays robust versions of goodness-of-fit statistics for the model.

The following statements invoke the ROBUSTREG procedure with LTS estimation, which was used by Zaman, Rousseeuw, and Orhan (2001). The results are consistent with those of M estimation.

```plaintext
proc robustreg method=lts(h=33) fwls data=growth;
  model GDP = LFG GAP EQP NEQ / diagnostics leverage;
  output out=robout r=resid sr=stdres;
run;
```

R-Square for LTS Estimation

R-Square 0.7418

Output 62.3.7 displays outlier and leverage point diagnostics based on the LTS estimates.
Output 62.3.8 displays the final weighted least squares estimates, which are identical to those reported in Zaman, Rousseeuw, and Orhan (2001).

References

Chapter 63
The RSREG Procedure

Overview

The RSREG procedure uses the method of least squares to fit quadratic response surface regression models. Response surface models are a kind of general linear model in which attention focuses on characteristics of the fit response function and in particular, where optimum estimated response values occur.

In addition to fitting a quadratic function, you can use the RSREG procedure to

- test for lack of fit
- test for the significance of individual factors
- analyze the canonical structure of the estimated response surface
- compute the ridge of optimum response
- predict new values of the response

Comparison to Other SAS Software

Other SAS/STAT procedures can be used to fit the response surface, but the RSREG procedure is more specialized. The following statements model a three-factor response surface in PROC RSREG:

```sas
proc rsreg;
   model y=x1 x2 x3;
run;
```

These statements are more compact than the statements for other regression procedures in SAS/STAT software. For example, the equivalent statements for the GLM procedure are

```sas
proc glm;
   model y=x1 x1*x1
       x2 x1*x2 x2*x2
       x3 x1*x3 x2*x3 x3*x3;
run;
```

Additionally, PROC RSREG includes specialized methodology for analyzing the fitted response surface, such as canonical analysis and optimum response ridges.

Note that the ADX Interface in SAS/QC software provides an interactive environment for constructing and analyzing many different kinds of experiments, including response surface experiments. The ADX Interface is the preferred interactive SAS
System tool for analyzing experiments, since it includes facilities for checking underlying assumptions and graphically optimizing the response surface. The RSREG procedure is appropriate for analyzing experiments in a batch environment.

**Terminology**

Variables are referred to according to the following conventions:

- **factor variables**: independent variables used in constructing the quadratic response surface. To estimate the necessary parameters, each variable must have at least three distinct values in the data. Independent variables must be numeric.

- **response variables**: the dependent variables to which the quadratic response surface is fit. Dependent variables must be numeric.

- **covariates**: additional independent variables for use in the regression but not in the formation of the quadratic response surface. Covariates must be numeric.

- **WEIGHT variable**: a variable for weighting the observations in the regression. The WEIGHT variable must be numeric.

- **ID variables**: variables not in the above lists that are transferred to an output data set containing statistics for each observation in the input data set. This data set is created using the OUT= option in the PROC RSREG statement. ID variables can be either character or numeric.

- **BY variables**: variables for grouping observations. Separate analyses are obtained for each BY group. BY variables can be either character or numeric.

**Getting Started**

**A Response Surface with a Simple Optimum**

This example uses the three-factor quadratic model discussed in John (1971). Schneider and Stockett (1963) performed an experiment aimed at reducing the unpleasant odor of a chemical produced with several factors. The objective is to minimize the unpleasant odor of a chemical. The following statements read the data.

```plaintext
title 'Response Surface with a Simple Optimum';
data smell;
   input Odor T R H @@;
   label
      T = "Temperature"
      R = "Gas-Liquid Ratio"
      H = "Packing Height";
datalines;
   66 40 .3 4 39 120 .3 4 43 40 .7 4 49 120 .7 4
```
The INPUT statement names the variables contained in the SAS data set `smell`; the variable `Odor` is the response, while the variables `T`, `R`, and `H` are the independent factors.

The following statements invoke PROC RSREG on the data set `smell`. Figure 63.1 through Figure 63.3 display the results of the analysis, including a lack-of-fit test requested with the LACKFIT option.

```sas
proc rsreg data=smell;
  model Odor = T R H / lackfit;
run;
```

**Figure 63.1.** Summary Statistics and Analysis of Variance

Figure 63.1 displays the coding coefficients for the transformation of the independent variables to lie between $-1$ and $1$, simple statistics for the response variable,
hypothesis tests for linear, quadratic, and crossproduct terms, and the lack-of-fit test. The hypothesis tests can be used to gain a rough idea of importance of the effects; here the crossproduct terms are not significant. However, the lack-of-fit for the model is significant, so more complicated modeling or further experimentation with additional variables should be performed before firm statements are made concerning the underlying process.

**Figure 63.2.** Parameter Estimates and Hypothesis Tests

Parameter estimates and the factor ANOVA are shown in **Figure 63.2**. Looking at the parameter estimates, you can see that the crossproduct terms are not significantly different from zero, as noted previously. The “Estimate” column contains estimates based on the raw data, and the “Parameter Estimate from Coded Data” column contains those based on the coded data. The factor ANOVA table displays tests for all four parameters corresponding to each factor—the parameters corresponding to the linear effect, the quadratic effect, and the effects of the cross products with each of the other two factors. The only factor with a significant overall effect is R, indicating that the level of noise left unexplained by the model is still too high to estimate the effects of T and H accurately. This may be due to the lack of fit.

Figure 63.3. Canonical Analysis and Eigenvectors

Figure 63.3 contains the canonical analysis and eigenvectors. The canonical analysis indicates that the directions of principle orientation for the predicted response surface are along the axes associated with the three factors, confirming the small interaction effect in the Regression ANOVA. The largest eigenvalue (48.8588) corresponds to the eigenvector \[ \{0.238091, 0.971116, -0.015690\} \], the largest component of which (0.971116) is associated with \( R \); similarly, the second largest eigenvalue (31.1035) is associated with \( T \). The third eigenvalue (6.0377), associated with \( H \), is quite a bit smaller than the other two, indicating that the response surface is relatively insensitive to changes in this factor. The coded form of the canonical analysis indicates that the estimated response surface is at a minimum when \( T \) and \( R \) are both near the middle of their respective ranges and \( H \) is relatively high; in uncoded, terms, the model predicts that the unpleasant odor will be minimized when \( T = 84.876502 \), \( R = 0.539915 \), and \( H = 7.541050 \).

To plot the response surface with respect to two of the factor variables, first fix \( H \), the least significant factor variable, at its estimated optimum value and generate a grid of points for \( T \) and \( R \). To ensure that the grid data do not affect parameter estimates, the response variable (Odor) is set to missing. (See the “Missing Values” section on page 4048.) The following statements produce and graph the necessary data. Initial data steps creates a grid over \( T \) and \( R \), with \( H \) set to a constant value, and combine this grid with the original data. Then, PROC RSREG is used to create predictions for the combined data. Finally, PROC G3D is used to create a surface plot of the predictions.
data grid;
  do;
    Odor = .;
    H = 7.541;
    do T = 20 to 140 by 5;
      do R = .1 to .9 by .05;
        output;
      end;
    end;
  end;
end;

data grid;
  set smell grid;
run;

proc rsreg data=grid out=predict noprint;
  model Odor = T R H / predict;
run;

data plot;
  set predict;
  if H = 7.541;
proc g3d data=plot;
  plot T*R=Odor / rotate=38 tilt=75 xticknum=3 yticknum=3
       zmax=300 zmin=-60 ctop=red cbottom=blue caxis=black;
run;

The first DATA step creates grid points for T and R at H=7.541 and sets Odor to missing, and the second DATA step concatenates these grid points with the original data. Predicted values are created in the SAS data set predict by invoking the RSREG procedure with the PREDICT option in the MODEL statement. The analysis is not displayed due to theNOPRINT option. The third DATA step subsets the predicted values over just the grid points (excluding the predictions at the original points). PROC G3D is then used to create the three-dimensional plot shown in Figure 63.4.
PROC RSREG Statement ★ 4039

Figure 63.4. The Response Surface Obtained from the PREDICT Option

Syntax

The following statements are available in PROC RSREG.

PROC RSREG < options > ;
  MODEL responses= independents < / options > ;
  RIDGE < options > ;
  WEIGHT variable ;
  ID variables ;
  BY variables ;

The PROC RSREG and MODEL statements are required. The BY, ID, MODEL, RIDGE, and WEIGHT statements are described after the PROC RSREG statement, and they can appear in any order.

PROC RSREG Statement

PROC RSREG < options > ;

The PROC RSREG statement invokes the procedure. You can specify the following options in the PROC RSREG statement.
DATA=SAS-data-set
specifies the input SAS data set that contains the data to be analyzed. By default, PROC RSREG uses the most recently created SAS data set.

NOPRINT
suppresses the normal display of results when only the output data set is required. For more information, see the description of the NOPRINT option in the “MODEL Statement” and “RIDGE Statement” sections. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 14, “Using the Output Delivery System,” for more information.

OUT=SAS-data-set
creates an output SAS data set that contains statistics for each observation in the input data set. In particular, this data set contains the BY variables, the ID variables, the WEIGHT variable, the variables in the MODEL statement, and the output options requested in the MODEL statement. You must specify output options in the MODEL statement; otherwise, the output data set is created but contains no observations. To create a permanent SAS data set, you must specify a two-level name (refer to the discussion in SAS Language Reference: Concepts for more information on permanent SAS data sets). For details on the data set created by PROC RSREG, see the “Output Data Sets” section on page 4051.

BY Statement

BY  variables ;

You can specify a BY statement with PROC RSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the RSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure (in base SAS software).

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.
**ID Statement**

```plaintext
ID variables;
```

The ID statement names variables that are to be transferred to the data set created by the OUT= option in the PROC RSREG statement.

**MODEL Statement**

```plaintext
MODEL responses=independents < / options >;
```

The MODEL statement lists response (dependent) variables followed by an equal sign and then lists independent variables, some of which may be covariates. The output options to the MODEL statement specify which statistics are output to the data set created using the OUT= option in the PROC RSREG statement. If none of the options are selected, the data set is created but contains no observations. The option keywords become values of the special variable _TYPE_ in the output data set. Any of the following options can be specified.

</tr>
</tbody>
</table>

**ACTUAL**

specifies that the observed response values from the input data set be written to the output data set.

**BYOUT**

uses only the first BY group to estimate the model. Subsequent BY groups have scoring statistics computed in the output data set only. The BYOUT option is used only when a BY statement is specified.
COVAR=n
declares that the first \( n \) variables on the right-hand side of the model are simple linear regressors (covariates) and not factors in the quadratic response surface. By default, PROC RSREG forms quadratic and crossproduct effects for all regressor variables in the MODEL statement. See the “Handling Covariates” section on page 4050 for more details and Example 63.2 on page 4059 for an example using covariates.

D
specifies that Cook’s \( D \) influence statistic be written to the output data set. See Chapter 2, “Introduction to Regression Procedures,” for details and formulas.

LACKFIT
performs a lack-of-fit test. Refer to Draper and Smith (1981) for a discussion of lack-of-fit tests.

L95
specifies that the lower bound of a 95\% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates. See Chapter 2 for details and formulas.

L95M
specifies that the lower bound of a 95\% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates. See Chapter 2 for details and formulas.

NOANOVA
NOAOV
suppresses the display of the analysis of variance and parameter estimates from the model fit.

NOCODE
performs the canonical and ridge analyses with the parameter estimates derived from fitting the response to the original values of the factors variables, rather than their coded values (see the “Coding the Factor Variables” section on page 4047 for more details.) Use this option if the data are already stored in a coded form.

NOOPTIMAL
NOOPT
suppresses the display of the canonical analysis for the quadratic response surface.

NOPRINT
suppresses the display of both the analysis of variance and the canonical analysis.

PREDICT
specifies that the values predicted by the model be written to the output data set.

PRESS
computes and displays the predicted residual sum of squares (PRESS) statistic for each dependent variable in the model. The PRESS statistic is added to the summary information at the beginning of the analysis of variance, so if the NOANOVA or
NOPRINT option is specified, PRESS has no effect. See Chapter 2 for details and formulas.

RESIDUAL
specifies that the residuals, calculated as ACTUAL − PREDICTED, be written to the output data set.

U95
specifies that the upper bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates. See Chapter 2 for details and formulas.

U95M
specifies that the upper bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates. See Chapter 2 for details and formulas.

RIDGE Statement

RIDGE < options > ;

A RIDGE statement computes the ridge of optimum response. The ridge starts at a given point $x_0$, and the point on the ridge at radius $r$ from $x_0$ is the collection of factor settings that optimizes the predicted response at this radius. You can think of the ridge as climbing or falling as fast as possible on the surface of predicted response. Thus, the ridge analysis can be used as a tool to help interpret an existing response surface or to indicate the direction in which further experimentation should be performed.

The default starting point, $x_0$, has each coordinate equal to the point midway between the highest and lowest values of the factor in the design. The default radii at which the ridge is computed are 0, 0.1, . . . , 0.9, 1. If, as usual, the ridge analysis is based on the response surface fit to coded values for the factor variables (see the “Coding the Factor Variables” section on page 4047 for details), then this results in a ridge that starts at the point with a coded zero value for each coordinate and extends toward, but not beyond, the edge of the range of experimentation. Alternatively, both the center point for the ridge and the radii at which it is to be computed can be specified.

You can specify the following options in the RIDGE statement:

CENTER=uncoded-factor-values

gives the coordinates of the point $x_0$ from which to begin the ridge. The coordinates should be given in the original (uncoded) factor variable values and should be separated by commas. There must be as many coordinates specified as there are factors in the model, and the order of the coordinates must be the same as that used in the MODEL statement. This starting point should be well inside the range of experimentation. The default sets each coordinate equal to the value midway between the highest and lowest values for the associated factor.
Chapter 63. The RSREG Procedure

MAXIMUM

computes the ridge of maximum response. Both the MIN and MAX options can be specified; at least one must be specified.

MINIMUM

computes the ridge of minimum response. Both the MIN and MAX options can be specified; at least one must be specified.

NOPRINT

suppresses the display of the ridge analysis when only an output data set is required.

OUTR=SAS-data-set

creates an output SAS data set containing the computed optimum ridge. For details, see the “Output Data Sets” section on page 4051.

RADIUS=coded-radii

gives the distances from the ridge starting point at which to compute the optimum. The values in the list represent distances between coded points. The list can take any of the following forms or can be composed of mixtures of them:

- $m_1, m_2, \ldots, m_n$ several values
- $m$ TO $n$ a sequence where $m$ equals the starting value, $n$ equals the ending value, and the increment equals 1
- $m$ TO $n$ BY $i$ a sequence where $m$ equals the starting value, $n$ equals the ending value, and $i$ equals the increment

Mixtures of the preceding forms should be separated by commas. The default list runs from 0 to 1 by increments of 0.1. The following are examples of valid lists.

- $radius=0$ to $5$ by $0.5$;
- $radius=0, 0.2, 0.25, 0.3, 0.5$ to $1.0$ by $0.1$;

WEIGHT Statement

WEIGHT variable;

When a WEIGHT statement is used, a weighted residual sum of squares

$$\sum_{i} w_i (y_i - \hat{y}_i)^2$$

is minimized, where $w_i$ is the value of the variable specified in the WEIGHT statement, $y_i$ is the observed value of the response variable, and $\hat{y}_i$ is the predicted value of the response variable.

The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than zero. The WEIGHT statement has no effect on degrees of freedom or number of observations. If the weights for the observations are proportional to the reciprocals of the error variances, then the weighted least-squares estimates are best linear unbiased estimators (BLUE).
Introduction to Response Surface Experiments

Many industrial experiments are conducted to discover which values of given factor variables optimize a response. If each factor is measured at three or more values, a quadratic response surface can be estimated by least-squares regression. The predicted optimal value can be found from the estimated surface if the surface is shaped like a simple hill or a valley. If the estimated surface is more complicated, or if the predicted optimum is far from the region of experimentation, then the shape of the surface can be analyzed to indicate the directions in which new experiments should be performed.

Suppose that a response variable \( y \) is measured at combinations of values of two factor variables, \( x_1 \) and \( x_2 \). The quadratic response-surface model for this variable is written as

\[
y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1^2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + \epsilon
\]

The steps in the analysis for such data are

1. model fitting and analysis of variance to estimate parameters
2. canonical analysis to investigate the shape of the predicted response surface
3. ridge analysis to search for the region of optimum response

Model Fitting and Analysis of Variance

The first task in analyzing the response surface is to estimate the parameters of the model by least-squares regression and to obtain information about the fit in the form of an analysis of variance. The estimated surface is typically curved: a “hill” whose peak occurs at the unique estimated point of maximum response, a “valley,” or a “saddle-surface” with no unique minimum or maximum. Use the results of this phase of the analysis to answer the following questions:

- What is the contribution of each type of effect—linear, quadratic, and crossproduct—to the statistical fit? The ANOVA table with sources labeled “Regression” addresses this question.
- What part of the residual error is due to lack of fit? Does the quadratic response model adequately represent the true response surface? If you specify the LACKFIT option in the MODEL statement, then the ANOVA table with sources labeled “Residual” addresses this question.
- What is the contribution of each factor variable to the statistical fit? Can the response be predicted as well if the variable is removed? The ANOVA table with sources labeled “Factor” addresses this question.
- What are the predicted responses for a grid of factor values? (See the section “Plotting the Surface” on page 4048 and the “Searching for Multiple Response Conditions” section on page 4048.)
Lack-of-Fit Test

The test for lack-of-fit compares the variation around the model with “pure” variation within replicated observations. This measures the adequacy of the quadratic response surface model. In particular, if there are \( n_i \) replicated observations \( Y_{i1}, \ldots, Y_{in_i} \) of the response all at the same values \( x_i \) of the factors, then we can predict the true response at \( x_i \) either by using the predicted value \( \hat{Y}_i \) based on the model or by using the mean \( \bar{Y}_i \) of the replicated values. The test for lack-of-fit decomposes the residual error into a component due to the variation of the replications around their mean value (the “pure” error), and a component due to the variation of the mean values around the model prediction (the “bias” error):

\[
\sum_i n_i \sum_{j=1}^{n_i} (Y_{ij} - \hat{Y}_i)^2 = \sum_i n_i \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2 + \sum_i n_i (\bar{Y}_i - \hat{Y}_i)^2
\]

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the LACKFIT option in the MODEL statement. Note that, since all other tests use total error rather than pure error, you may want to hand-calculate the tests with respect to pure error if the lack-of-fit is significant. On the other hand, significant lack-of-fit indicates the quadratic model is inadequate, so if this is a problem you can also try to refine the model, possibly using PROC GLM for general polynomial modeling; refer to Chapter 32, “The GLM Procedure,” for more information. Example 63.1 on page 4055 illustrates the use of the LACKFIT option.

Canonical Analysis

The second task in analyzing the response surface is to examine the overall shape of the curve and determine whether the estimated stationary point is a maximum, a minimum, or a saddle point. The canonical analysis can be used to answer the following questions:

- Is the surface shaped like a hill, a valley, a saddle surface, or a flat surface?
- If there is a unique optimum combination of factor values, where is it?
- To which factor or factors are the predicted responses most sensitive?

The eigenvalues and eigenvectors in the matrix of second-order parameters characterize the shape of the response surface. The eigenvectors point in the directions of principle orientation for the surface, and the signs and magnitudes of the associated eigenvalues give the shape of the surface in these directions. Positive eigenvalues indicate directions of upward curvature, and negative eigenvalues indicate directions of downward curvature. The larger an eigenvalue is in absolute value, the more pronounced is the curvature of the response surface in the associated direction. Often, all of the coefficients of an eigenvector except for one are relatively small, indicating that the vector points roughly along the axis associated with the factor corresponding...
to the single large coefficient. In this case, the canonical analysis can be used to determine the relative sensitivity of the predicted response surface to variations in that factor. (See the “Getting Started” section on page 4034 for an example.)

**Ridge Analysis**

If the estimated surface is found to have a simple optimum well within the range of experimentation, the analysis performed by the preceding two steps may be sufficient. In more complicated situations, further search for the region of optimum response is required. The method of ridge analysis computes the estimated ridge of optimum response for increasing radii from the center of the original design. The ridge analysis answers the following question:

- If there is not a unique optimum of the response surface within the range of experimentation, in which direction should further searching be done in order to locate the optimum?

You can use the RIDGE statement to compute the ridge of maximum or minimum response.

**Coding the Factor Variables**

For the results of the canonical and ridge analyses to be interpretable, the values of different factor variables should be comparable. This is because the canonical and ridge analyses of the response surface are not invariant with respect to differences in scale and location of the factor variables. The analysis of variance is not affected by these changes. Although the actual predicted surface does not change, its parameterization does. The usual solution to this problem is to code each factor variable so that its minimum in the experiment is $-1$ and its maximum is $1$ and to carry through the analysis with the coded values instead of the original ones. This practice has the added benefit of making $1$ a reasonable boundary radius for the ridge analysis since $1$ represents approximately the edge of the experimental region. By default, PROC RSREG computes the linear transformation to perform this coding as the data are initially read in, and the canonical and ridge analyses are performed on the model fit to the coded data. The actual form of the coding operation for each value of a variable is

\[
\text{coded value} = \frac{(\text{original value} - M)}{S}
\]

where $M$ is the average of the highest and lowest values for the variable in the design and $S$ is half their difference.
Missing Values

If an observation has missing data for any of the variables used by the procedure, then that observation is not used in the estimation process. If one or more response variables are missing, but no factor or covariate variables are missing, then predicted values and confidence limits are computed for the output data set, but the residual and Cook’s D statistic are missing.

Plotting the Surface

You can generate predicted values for a grid of points with the PREDICT option (see the “Getting Started” section on page 4034 for an example) and then use these values to create a contour plot or a three-dimensional plot of the response surface over a two-dimensional grid. Any two factor variables can be chosen to form the grid for the plot. Several plots can be generated by using different pairs of factor variables.

Searching for Multiple Response Conditions

Suppose you want to find the factor setting that produces responses in a certain region. For example, you have the following data with two factors and three responses:

```plaintext
data a;
  input x1 x2 y1 y2 y3;
datalines;
-1 -1  1.8  1.940  3.6398
-1  1  2.6  1.843  4.9123
  1 -1  5.4  1.063  6.0128
  1  1  0.7  1.639  2.3629
  0  0  8.5  0.134  9.0910
  0  0  3.0  0.545  3.7349
  0  0  9.8  0.453 10.4412
  0  0  4.1  1.117  5.0042
  0  0  4.8  1.690  6.6245
  0  0  5.9  1.165  6.9420
  0  0  7.3  1.013  8.7442
  0  0  9.3  1.179 10.2762
  1.4142  0  3.9  0.945  5.0245
-1.4142  0  1.7  0.333  2.4041
  0  1.4142  3.0  1.869  5.2695
  0 -1.4142  5.7  0.099  5.4346
;
```

You want to find the values of x1 and x2 that maximize y1 subject to y2<2 and y3<y2+y1. The exact answer is not easy to obtain analytically, but you can obtain a practically feasible solution by checking conditions across a grid of values in the range of interest. First, append a grid of factor values to the observed data, with missing values for the responses.

```plaintext
data b;
  set a end=eof;
```
output;
if eof then do;
y1=.;
y2=.;
y3=.;
do x1=-2 to 2 by .1;
do x2=-2 to 2 by .1;
output;
end;
end;
end;
run;

Next, use PROC RSREG to fit a response surface model to the data and to compute predicted values for both the observed data and the grid, putting the predicted values in a data set c.

```
proc rsreg data=b out=c;
    model y1 y2 y3=x1 x2 / predict;
run;
```

Finally, find the subset of predicted values that satisfy the constraints, sort by the unconstrained variable, and display the top five predictions.

```
data d;
    set c;
    if y2<2;
    if y3<y2+y1;

    proc sort data=d;
        by descending y1;
    run;

data d; set d;
    i = _n_; 
    proc print;
        where (i <= 5);
    run;
```

The final results are displayed in Figure 63.5. They indicate that optimal values of the factors are around 0.3 for x1 and around -0.5 for x2.

**Figure 63.5.** Top Five Predictions
Handling Covariates

Covariate regressors are added to a response surface model because they are believed to account for a sizable yet relatively uninteresting portion of the variation in the data. What the experimenter is really interested in is the response corrected for the effect of the covariates. A common example is the block effect in a block design. In the canonical and ridge analyses of a response surface, which estimate responses at hypothetical levels of the factor variables, the actual value of the predicted response is computed using the average values of the covariates. The estimated response values do optimize the estimated surface of the response corrected for covariates, but true prediction of the response requires actual values for the covariates. You can use the COVAR= option in the MODEL statement to include covariates in the response surface model. Example 63.2 on page 4059 illustrates the use of this option.

Computational Method

Canonical Analysis

For each response variable, the model can be written in the form

\[ y_i = x_i'Ax_i + b'x_i + c'z_i + \epsilon_i \]

where

- \( y_i \) is the \( i \)th observation of the response variable.
- \( x_i = (x_{i1}, x_{i2}, \ldots, x_{ik})' \) are the \( k \) factor variables for the \( i \)th observation.
- \( z_i = (z_{i1}, z_{i2}, \ldots, z_{iL})' \) are the \( L \) covariates, including the intercept term.
- \( A \) is the \( k \times k \) symmetrized matrix of quadratic parameters, with diagonal elements equal to the coefficients of the pure quadratic terms in the model and off-diagonal elements equal to half the coefficient of the corresponding cross product.
- \( b \) is the \( k \times 1 \) vector of linear parameters.
- \( c \) is the \( L \times 1 \) vector of covariate parameters, one of which is the intercept.
- \( \epsilon_i \) is the error associated with the \( i \)th observation. Tests performed by PROC RSREG assume that errors are independently and normally distributed with mean zero and variance \( \sigma^2 \).

The parameters in \( A, b, \) and \( c \) are estimated by least squares. To optimize \( y \) with respect to \( x \), take partial derivatives, set them to zero, and solve:

\[ \frac{\partial y}{\partial x} = 2x'Ax + b' = 0 \implies x = -\frac{1}{2}A^{-1}b \]

You can determine if the solution is a maximum or minimum by looking at the eigenvalues of \( A \):
If the eigenvalues are all negative then the solution is a maximum
are all positive a minimum
have mixed signs a saddle point
contain zeros in a flat area

Ridge Analysis

The eigenvector for the largest eigenvalue gives the direction of steepest ascent from the stationary point, if positive, or steepest descent, if negative. The eigenvectors corresponding to small or zero eigenvalues point in directions of relative flatness.

The point on the optimum response ridge at a given radius \( R \) from the ridge origin is found by optimizing

\[
(x_0 + d)'A(x_0 + d) + b'(x_0 + d)
\]

over \( d \) satisfying \( d'd = R^2 \), where \( x_0 \) is the \( k \times 1 \) vector containing the ridge origin and \( A \) and \( b \) are as previously discussed. By the method of Lagrange multipliers, the optimal \( d \) has the form

\[
d = -(A - \mu I)^{-1}(Ax_0 + 0.5b)
\]

where \( I \) is the \( k \times k \) identity matrix and \( \mu \) is chosen so that \( d'd = R^2 \). There may be several values of \( \mu \) that satisfy this constraint; the right one depends on which sort of response ridge is of interest. If you are searching for the ridge of maximum response, then the appropriate \( \mu \) is the unique one that satisfies the constraint and is greater than all the eigenvalues of \( A \). Similarly, the appropriate \( \mu \) for the ridge of minimum response satisfies the constraint and is less than all the eigenvalues of \( A \). (Refer to Myers and Montgomery (1995) for details.)

Output Data Sets

**OUT=SAS-data-set**

An output data set containing statistics requested with options in the MODEL statement for each observation in the input data set is created whenever the OUT= option is specified in the PROC RSREG statement. The data set contains the following variables.

- the BY variables
- the ID variables
- the WEIGHT variable
- the independent variables in the MODEL statement
• the variable _TYPE_, which identifies the observation type in the output data set. _TYPE_ is a character variable with a length of eight, and it takes on the values 'ACTUAL', 'PREDICT', 'RESIDUAL', 'U95M', 'L95M', 'U95', 'L95', and 'D', corresponding to the options specified.

• the response variables containing special output values identified by the _TYPE_ variable

All confidence limits use the two-tailed Student’s t value.

**OUTR=SAS-data-set**

An output data set containing the optimum response ridge is created when the OUTR= option is specified in the RIDGE statement. The data set contains the following variables:

• the current values of the BY variables

• a character variable _DEPVAR_ containing the name of the dependent variable

• a character variable _TYPE_ identifying the type of ridge being computed, MINIMUM or MAXIMUM. If both MAXIMUM and MINIMUM are specified, the data set contains observations for the minimum ridge followed by observations for the maximum ridge.

• a numeric variable _RADIUS_ giving the distance from the ridge starting point

• the values of the model factors at the estimated optimum point at distance _RADIUS_ from the ridge starting point

• a numeric variable _PRED_, which is the estimated expected value of the dependent variable at the optimum

• a numeric variable _STDERR_, which is the standard error of the estimated expected value

**Displayed Output**

All estimates and hypothesis tests assume that the model is correctly specified and the errors are distributed according to classical statistical assumptions.

The output displayed by PROC RSREG includes the following.

**Estimation and Analysis of Variance**

• The actual form of the coding operation for each value of a variable is

\[
\text{coded value} = \frac{1}{S} (\text{original value} - M)
\]

where \(M\) is the average of the highest and lowest values for the variable in the design and \(S\) is half their difference. The Subtracted off column contains the \(M\) values for this formula for each factor variable, and \(S\) is found in the Divided by column.
The summary table for the response variable contains the following information.

- **Response Mean** is the mean of the response variable in the sample. When a WEIGHT statement is used, the mean $\bar{y}$ is calculated by
  \[
  \bar{y} = \frac{\sum_i w_i y_i}{\sum_i w_i}
  \]
- **Root MSE** estimates the standard deviation of the response variable and is calculated as the square root of the Total Error mean square.
- The **R-Square** value is $R^2$, or the coefficient of determination. $R^2$ measures the proportion of the variation in the response that is attributed to the model rather than to random error.
- The **Coefficient of Variation** is 100 times the ratio of the Root MSE to the Response Mean.

A table analyzing the significance of the terms of the regression is displayed. Terms are brought into the regression in four steps: (1) the Intercept and any covariates in the model, (2) Linear terms like $X_1$ and $X_2$, (3) pure Quadratic terms like $X_1^2$ or $X_2^2$, and (4) Crossproduct terms like $X_1 X_2$.

- The **Degrees of Freedom** should be the same as the number of corresponding parameters unless one or more of the parameters are not estimable.
- **Type I Sum of Squares**, also called the sequential sums of squares, measure the reduction in the error sum of squares as sets of terms (Linear, Quadratic, and so forth) are added to the model.
- **R-Square** measures the portion of total $R^2$ contributed as each set of terms (Linear, Quadratic, and so forth) is added to the model.
- Each F Value tests the null hypothesis that all parameters in the term are zero using the Total Error mean square as the denominator. This item is a test of a Type I hypothesis, containing the usual $F$ test numerator, conditional on the effects of subsequent variables not being in the model.
- $Pr > F$ is the significance value or probability of obtaining at least as great an $F$ ratio given that the null hypothesis is true.

The Total Error Sum of Squares can be partitioned into Lack of Fit and Pure Error. When Lack of Fit is significant, there is variation around the model other than random error (such as cubic effects of the factor variables).

- The **Total Error Mean Square** estimates $\sigma^2$, the variance.
- F Value tests the null hypothesis that the variation is adequately described by random error.

A table containing the parameter estimates from the model is displayed.

- The **Parameter Estimate** column contains the parameter estimates based on the *uncoded* values of the factor variables. If an effect is a linear combination of previous effects, the parameter for the effect is not estimable. When this happens, the degrees of freedom are zero, the parameter estimate is set to zero, and the estimates and tests on other parameters are conditional on this parameter being zero.
The Standard Error column contains the estimated standard deviations of the parameter estimates based on uncoded data.

The t Value column contains t values of a test of the null hypothesis that the true parameter is zero when the uncoded values of the factor variables are used.

Pr > |T| gives the significance value or probability of a greater absolute t ratio given that the true parameter is zero.

The Parameter Estimate from Coded Data column contains the parameter estimates based on the coded values of the factor variables. These are the estimates used in the subsequent canonical and ridge analyses.

The sum of squares are partitioned by the Factors in the model, and an analysis table is displayed. The test on a factor, say X1, is a joint test on all the parameters involving that factor. For example, the test for X1 tests the null hypothesis that the true parameters for X1, X1*X1, and X1*X2 are all zero.

**Canonical Analysis**

- The Critical Value columns contains the values of the factor variables that correspond to the stationary point of the fitted response surface. The critical values can be at a minimum, maximum, or saddle point.
- The Eigenvalues and Eigenvectors are from the matrix of quadratic parameter estimates based on the coded data. They characterize the shape of the response surface.

**Ridge Analysis**

- Coded Radius is the distance from the coded version of the associated point to the coded version of the origin of the ridge. The origin is given by the point at radius zero.
- Estimated Response is the estimated value of the response variable at the associated point. The Standard Error of this estimate is also given. This quantity is useful for assessing the relative credibility of the prediction at a given radius. Typically, this standard error increases rapidly as the ridge moves up to and beyond the design perimeter, reflecting the inherent difficulty of making predictions beyond the range of experimentation.
- Uncoded Factor Values are the values of the uncoded factor variables that give the optimum response at this radius from the ridge origin.

**ODS Table Names**

PROC RSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information on ODS, see Chapter 14, “Using the Output Delivery System.”
Example 63.1. A Saddle-Surface Response Using Ridge Analysis

Frankel (1961) reports an experiment aimed at maximizing the yield of mercaptobenzothiazole (MBT) by varying processing time and temperature. Myers (1976) uses a two-factor model in which the estimated surface does not have a unique optimum. A ridge analysis is used to determine the region in which the optimum lies. The objective is to find the settings of time and temperature in the processing of a chemical that maximize the yield. The following statements read the data and invoke PROC RSREG. These statements produce Output 63.1.1 through Output 63.1.5:

```plaintext
data d;
  input Time Temp MBT;
  label Time = "Reaction Time (Hours)"
                 Temp = "Temperature (Degrees Centigrade)"
                 MBT = "Percent Yield Mercaptobenzothiazole";
datalines;
  4.0   250   83.8
  20.0  250   81.7
  12.0  250   82.4
  12.0  250   82.9
  12.0  220   84.7
  12.0  280   57.9
  12.0  250   81.2
  6.3   229   81.3
  6.3   271   83.1
  17.7  229   85.3
  17.7  271   72.7
  4.0   250   82.0
;
proc sort;
  by Time Temp;
run;
```

Output 63.1.2 shows that the lack of fit for the model is highly significant. Since the quadratic model does not fit the data very well, firm statements about the underlying process should not be based only on the current analysis. Note from the analysis of variance for the model that the test for the time factor is not significant. If further experimentation is undertaken, it might be best to fix Time at a moderate to high value and to concentrate on the effect of temperature. In the actual experiment discussed here, extra runs were made that confirmed the results of the following analysis.

**Output 63.1.3. Canonical Analysis**

The canonical analysis (Output 63.1.3) indicates that the predicted response surface is shaped like a saddle. The eigenvalue of 2.5 shows that the valley orientation of the saddle is less curved than the hill orientation, with eigenvalue of $9.99$. The coefficients of the associated eigenvectors show that the valley is more aligned with Time and the hill with Temp. Because the canonical analysis resulted in a saddle point, the estimated surface does not have a unique optimum.

**Output 63.1.4. Ridge Analysis**

The ridge analysis (Output 63.1.4) provides the estimated ridge of maximum response for variable MBT: Percent Yield Mercaptobenzothiazole.
However, the ridge analysis in Output 63.1.4 indicates that maximum yields will result from relatively high reaction times and low temperatures. A contour plot of the predicted response surface, shown in Output 63.1.5, confirms this conclusion.

Output 63.1.5. Contour Plot of Predicted Response Surface

The statements that produce this plot follow. Note that contour and three-dimensional plots can be created interactively using SAS/INSIGHT software or the ADX Interface in SAS/QC software. Initial DATA steps create a grid over Time and Temp and combine this grid with the original data, using a variable flag to indicate the grid. Then, PROC RSREG is used to create predictions for the combined data. Finally, PROC GCONTOUR to displays a contour plot of the predictions over just the grid.

data b;
  set d;
  flag=1;
  MBT=.;
  do Time=0 to 20 by 1;
    do Temp=220 to 280 by 5;
      output;
    end;
  end;
  data c;
  set d b;
  proc rsreg data=c out=e noprint;
    model MBT=Time Temp / predict;
    id flag;
  run;
axis1 label=(angle=90) minor=none;
axis2 order=(220 to 280 by 20) minor=none;

proc gcontour data=e(where=(flag=1));
plot Time*Temp=MBT
   / nlevels=12 vaxis=axis1 haxis=axis2 nolegend autolabel
   llevels=2 2 2 1 1 1 1 1 1 1 1 1 ;
run;

Example 63.2. Response Surface Analysis with Covariates

One way of viewing covariates is as extra sources of variation in the dependent variable that may mask the variation due to primary factors. This example demonstrates the use of the COVAR= option in PROC RSREG to fit a response surface model to the dependent variable values corrected for the covariates.

You have a chemical process with a yield that you hypothesize to be dependent on three factors: reaction time, reaction temperature, and reaction pressure. You perform an experiment to measure this dependence. You are willing to include up to 20 runs in your experiment, but you can perform no more than 8 runs on the same day, so the design for the experiment is composed of three blocks. Additionally, you know that the grade of raw material for the reaction has a significant impact on the yield. You have no control over this, but you keep track of it. The following statements create a SAS data set containing the results of the experiment:

data Experiment;
  input Day Grade Time Temp Pressure Yield;
datalines;
1 67 -1 -1 -1 32.98
1 68 -1 1 1 47.04
1 70 1 -1 1 67.11
1 66 1 1 -1 26.94
1 74 0 0 0 103.22
1 68 0 0 0 42.94
2 75 -1 -1 1 122.93
2 69 -1 1 -1 62.97
2 70 1 -1 -1 72.96
2 71 1 1 1 94.93
2 72 0 0 0 93.11
2 74 0 0 0 112.97
3 69 1.633 0 0 78.88
3 67 -1.633 0 0 52.53
3 68 0 1.633 0 68.96
3 71 0 -1.633 0 92.56
3 70 0 0 1.633 88.99
3 72 0 0 -1.633 102.50
3 70 0 0 0 82.84
3 72 0 0 0 103.12
;
Your first analysis neglects to take the covariates into account. The following statements use PROC RSREG to fit a response surface to the observed yield, but note that Day and Grade are omitted.

```plaintext
proc rsreg data=Experiment;
   model Yield = Time Temp Pressure;
run;
```

The ANOVA results (shown in Output 63.2.1) indicate that no process variable effects are significantly larger than the background noise.

**Output 63.2.1.** Analysis of Variance Ignoring Covariates

<table>
<thead>
<tr>

</table>

However, when the yields are adjusted for covariate effects of day and grade of raw material, very strong process variable effects are revealed. The following statements produce the ANOVA results in Output 63.2.2. Note that in order to include the effects of the classification factor Day as covariates, you need to create dummy variables indicating each day separately.

```plaintext
data Experiment; set Experiment;
   d1 = (Day = 1);
   d2 = (Day = 2);
   d3 = (Day = 3);
proc rsreg data=Experiment;
   model Yield = d1-d3 Grade Time Temp Pressure / covar=4;
run;
```
**Output 63.2.2. Analysis of Variance Including Covariates**

<table>

Chapter 64. The SCORE Procedure
Overview

The SCORE procedure multiplies values from two SAS data sets, one containing coefficients (for example, factor-scoring coefficients or regression coefficients) and the other containing raw data to be scored using the coefficients from the first data set. The result of this multiplication is a SAS data set containing linear combinations of the coefficients and the raw data values.

Many statistical procedures output coefficients that PROC SCORE can apply to raw data to produce scores. The new score variable is formed as a linear combination of raw data and scoring coefficients. For each observation in the raw data set, PROC SCORE multiplies the value of a variable in the raw data set by the matching scoring coefficient from the data set of scoring coefficients. This multiplication process is repeated for each variable in the VAR statement. The resulting products are then summed to produce the value of the new score variable. This entire process is repeated for each observation in the raw data set. In other words, PROC SCORE cross multiplies part of one data set with another.

Raw Data Set

The raw data set can contain the original data used to calculate the scoring coefficients, or it can contain an entirely different data set. The raw data set must contain all the variables needed to produce scores. In addition, the scoring coefficients and the variables in the raw data set that are used in scoring must have the same names. See the section “Getting Started” beginning on page 4067.

Scoring Coefficients Data Set

The data set containing scoring coefficients must contain two special variables: the _TYPE_ variable and the _NAME_ or _MODEL_ variable.

- The _TYPE_ variable identifies the observations that contain scoring coefficients.
- The _NAME_ or _MODEL_ variable provides a SAS name for the new score variable.

PROC SCORE first looks for a _NAME_ variable in the SCORE= input data set. If there is such a variable, the variable’s value is what SCORE uses to name the new score variable. If the SCORE= data set does not have a _NAME_ variable, then PROC SCORE looks for a _MODEL_ variable.

For example, PROC FACTOR produces an output data set that contains factor-scoring coefficients. In this output data set, the scoring coefficients are identified by
_TYPE_='SCORE'. For _TYPE_='SCORE', the _NAME_ variable has values of 'Factor1', 'Factor2', and so forth. PROC SCORE gives the new score variables the names Factor1, Factor2, and so forth.

As another example, the REG procedure produces an output data set that contains parameter estimates. In this output data set, the parameter estimates are identified by _TYPE_='PARMS'. The _MODEL_ variable contains the label used in the MODEL statement in PROC REG, or it uses MODELn if no label is specified. This label is the name PROC SCORE gives to the new score variable.

### Standardization of Raw Data

PROC SCORE automatically standardizes or centers the DATA= variables for you, based on information from the original variables and analysis from the SCORE= data set.

If the SCORE= scoring coefficients data set contains observations with _TYPE_='MEAN' and _TYPE_='STD', then PROC SCORE standardizes the raw data before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP without the COV option.

If the SCORE= scoring coefficients data set contains observations with _TYPE_='MEAN' but _TYPE_='STD' is absent, then PROC SCORE centers the raw data (the means are subtracted) before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP with the COV option.

If the SCORE= scoring coefficients data set does not contain observations with _TYPE_='MEAN' and _TYPE_='STD', or if you use the NOSTD option, then PROC SCORE does not center or standardize the raw data.

If the SCORE= scoring coefficients are obtained from observations with _TYPE_='USCORE', then PROC SCORE “standardizes” the raw data using the uncorrected standard deviations identified by _TYPE_='USTD', and the means are not subtracted from the raw data. For example, this type of SCORE= data set can come from PROC PRINCOMP with the NOINT option. For more information on _TYPE_='USCORE' scoring coefficients in TYPE=UCORR or TYPE=UCOV output data sets, see Appendix A, “Special SAS Data Sets.”

You can use PROC SCORE to score the data that were also used to generate the scoring coefficients, although more typically, scoring results are directly obtained from the OUT= data set in a procedure that computes scoring coefficients. When scoring new data, it is important to realize that PROC SCORE assumes that the new data have approximately the same scales as the original data. For example, if you specify the COV option with PROC PRINCOMP for the original analysis, the scoring coefficients in the PROC PRINCOMP OUTSTAT= data set are not appropriate for standardized data. With the COV option, PROC PRINCOMP will not output _TYPE_='STD' observations to the OUTSTAT= data set, and PROC SCORE will only subtract the means of the original (not new) variables from the new variables before multiplying. Without the COV option in PROC PRINCOMP, both the original variable means and standard deviations will be in the OUTSTAT= data set, and PROC SCORE will...
subtract the original variable means from the new variables and divide them by the original variable standard deviations before multiplying.

In general, procedures that output scoring coefficients in their OUTSTAT= data sets provide the necessary information for PROC SCORE to determine the appropriate standardization. However, if you use PROC SCORE with a scoring coefficients data set that you constructed without _TYPE_='MEAN' and _TYPE_='STD' observations, you might have to do the relevant centering or standardization of the new data first. If you do this, you must use the means and standard deviations of the original variables, that is, the variables that were used to generate the coefficients, not the means and standard deviations of the variables to be scored.

See the section “Getting Started” on page 4067 for further illustration.

### Getting Started

The SCORE procedure multiplies the values from two SAS data sets and creates a new data set to contain the results of the multiplication. The variables in the new data set are linear combinations of the variables in the two input data sets. Typically, one of these data sets contains raw data that you want to score, and the other data set contains scoring coefficients.

The following example demonstrates how to use the SCORE procedure to multiply values from two SAS data sets, one containing factor-scoring coefficients and the other containing raw data to be scored using the scoring coefficients.

Suppose you are interested in the performance of three different types of schools: private schools, state-run urban schools, and state-run rural schools. You want to compare the schools’ performances as measured by student grades on standard tests in English, mathematics, and biology. You administer these tests and record the scores for each of the three types of schools.

The following DATA step creates the SAS data set Schools. The data are provided by Chaseling (1996).

```sas
data Schools;
  input Type $ English Math Biology @@;
  datalines;
  p 52 55 45 p 42 49 40 p 63 64 54
  p 47 50 51 p 64 69 47 p 63 67 54
  p 59 63 42 p 56 61 41 p 41 44 72
  p 39 42 45 p 56 63 44 p 63 73 42
  p 62 68 46 p 51 61 51 p 45 56 54
  p 63 66 63 p 65 67 57 p 49 50 47
  p 47 48 34 p 53 54 46 p 49 40 43
  p 50 41 50 p 82 72 80 p 68 61 62
  p 68 61 46 p 63 53 48 p 77 72 74
  p 50 47 60 p 61 49 48 p 64 54 45
  p 60 53 40 p 80 69 75 p 76 69 77
  p 55 48 51 p 85 76 80 p 70 64 48
  p 61 51 61 p 51 47 58 p 78 72 79
```
The data set *Schools* contains the character variable *Type*, which represents the type of school. Valid values are p (private schools), r (state-run rural schools), and u (state-run urban schools).

The three numeric variables in the data set are *English*, *Math*, and *Biology*, which represent the student scores for English, mathematics, and biology, respectively. The double trailing at sign (@@) in the INPUT statement specifies that observations are input from each line until all values are read.

The following statements invoke the FACTOR procedure to compute the data set of factor scoring coefficients. The statements perform a principle components factor analysis using all three numeric variables in the SAS data set *Schools*. The OUTSTAT= option requests that PROC FACTOR output the factor scores to the data set *Scores*. The NOPRINT option suppresses display of the output.

```sas
proc factor data=Schools score outstat=Scores noprint;
   var english math biology;
run;
proc score data=schools score=Scores out=New;
   var english math biology;
   id type;
run;
```

The data set *Schools* contains the character variable *Type*, which represents the type of school. Valid values are p (private schools), r (state-run rural schools), and u (state-run urban schools).

The three numeric variables in the data set are *English*, *Math*, and *Biology*, which represent the student scores for English, mathematics, and biology, respectively. The double trailing at sign (@@) in the INPUT statement specifies that observations are input from each line until all values are read.

The following statements invoke the FACTOR procedure to compute the data set of factor scoring coefficients. The statements perform a principle components factor analysis using all three numeric variables in the SAS data set *Schools*. The OUTSTAT= option requests that PROC FACTOR output the factor scores to the data set *Scores*. The NOPRINT option suppresses display of the output.

```sas
proc factor data=Schools score outstat=Scores noprint;
   var english math biology;
run;
proc score data=schools score=Scores out=New;
   var english math biology;
   id type;
run;
```
The SCORE procedure is then invoked using `Schools` as the raw data set to be scored and `Scores` as the scoring data set. The `OUT=` option creates the SAS data set `New` to contain the linear combinations.

The `VAR` statement specifies that the variables `English`, `Math`, and `Biology` are used in computing scores. The `ID` statement copies the variable `Type` from the `Schools` data set to the output data set `New`.

The following statements print the SAS output data set `Scores`, the first two observations from the original data set `Schools`, and the first two observations of the resulting data set `New`.

```sas
title 'OUTSTAT= Data Set from PROC FACTOR';
proc print data=Scores;
run;

title 'First Two Observations of the DATA= Data Set from PROC SCORE';
proc print data=Schools(obs=2);
run;

title 'First Two Observations of the OUT= Data Set from PROC SCORE';
proc print data=New(obs=2);
run;
```

Figure 64.1 displays the output data set `Scores` produced by the FACTOR procedure. The last observation (observation number 11) contains the scoring coefficients ("_TYPE_"='SCORE'). Only one factor has been retained. Figure 64.1 also lists the first two observations of the original SAS data set `Schools` and the first two observations of the output data set `New` from the SCORE procedure.

Figure 64.1. Views of the Scores, Schools, and New Data Sets

The score variable Factor1 in the New data set is named according to the value of the _NAME_ variable in the Scores data set. The values of the variable Factor1 are computed as follows: the original data set variables are standardized to a mean of 0 and a variance of 1 because the Scores data set contains observations with _TYPE_=`MEAN` and _TYPE_=`STD`. These standardized variables are then multiplied by their respective standardized scoring coefficients from the data set Scores. These products are summed over all three variables, and the sum is the value of the new variable Factor1. The first two values of the scored variable Factor1 are obtained as follows:

\[
\left(\frac{52 - 55.525}{12.949} \times 0.390\right) + \left(\frac{55 - 52.325}{12.356} \times 0.378\right) + \left(\frac{45 - 50.350}{12.239} \times 0.347\right) = -0.17604
\]

\[
\left(\frac{42 - 55.525}{12.949} \times 0.390\right) + \left(\frac{49 - 52.325}{12.356} \times 0.378\right) + \left(\frac{40 - 50.350}{12.239} \times 0.347\right) = -0.80294
\]

The following statements request that the GCHART procedure produce a horizontal bar chart of the variable Type. The length of each bar represents the mean of the variable Factor1.
proc gchart;
   hbar type/type=mean sumvar=Factor1;
run;

Figure 64.2. Bar Chart of School Type

Figure 64.2 displays the mean score of the variable Factor1 for each of the three school types. For private schools (Type=p), the average value of the variable Factor1 is 0.384, while for state-run schools the average value is much lower. The state-run urban schools (Type=u) have the lowest mean value of -0.202, and the state-run rural schools (Type=r) have a mean value of -0.183.

Syntax

The following statements are available in the SCORE procedure.

PROC SCORE DATA= SAS-data-set < options > ;
   BY variables ;
   ID variables ;
   VAR variables ;

The only required statement is the PROC SCORE statement. The BY, ID, and VAR statements are described following the PROC SCORE statement.
PROC SCORE Statement

PROC SCORE DATA= SAS-data-set < options > ;

You can specify the following options in the PROC SCORE statement.

**DATA=**SAS-data-set
	names the input SAS data set containing the raw data to score. This specification is required.

**NOSTD**

suppresses centering and scaling of the raw data. Ordinarily, if PROC SCORE finds _TYPE_='MEAN', _TYPE_='USCORE', _TYPE_='USTD', or _TYPE_='STD' observations in the SCORE= data set, the procedure uses these to standardize the raw data before scoring.

**OUT=**SAS-data-set

specifies the name of the SAS data set created by PROC SCORE. If you want to create a permanent SAS data set, you must specify a two-level name. (Refer to “SAS Files” in SAS Language Reference: Concepts for more information on permanent SAS data sets.) If the OUT= option is omitted, PROC SCORE still creates an output data set and automatically names it according to the DATA=n convention, just as if you omitted a data set name in a DATA statement.

**PREDICT**

specifies that PROC SCORE should treat coefficients of \(-1\) in the SCORE= data set as 0. In regression applications, the dependent variable is coded with a coefficient of \(-1\). Applied directly to regression results, PROC SCORE produces negative residuals (see the description of the RESIDUAL option, which follows); the PREDICT option produces predicted values instead.

**RESIDUAL**

reverses the sign of each score. Applied directly to regression results, PROC SCORE produces negative residuals (PREDICT–ACTUAL); the RESIDUAL option produces positive residuals (ACTUAL–PREDICT) instead.

**SCORE=**SAS-data-set

names the data set containing the scoring coefficients. If you omit the SCORE= option, the most recently created SAS data set is used. This data set must have two special variables: _TYPE_ and either _NAME_ or _MODEL_.

**TYPE=**name | 'string'

specifies the observations in the SCORE= data set that contain scoring coefficients. The TYPE= procedure option is unrelated to the data set option that has the same name. PROC SCORE examines the values of the special variable _TYPE_ in the SCORE= data set. When the value of _TYPE_ matches TYPE=name, the observation in the SCORE= data set is used to score the raw data in the DATA= data set. If you omit the TYPE= option, scoring coefficients are read from observations with either _TYPE_='SCORE' or _TYPE_='USCORE'. Because the default for PROC SCORE is TYPE=SCORE, you need not specify the TYPE= option for factor scoring or for computing scores from OUTSTAT= data sets from the CANCORR, CANDISC,
PRINCOMP, or VARCLUS procedure. When you use regression coefficients from PROC REG, specify TYPE=PARMS.

The maximum length of the argument specified in the TYPE= option depends on the length defined by the VALIDVARNAME= SAS system option. For additional information, refer to SAS Language Reference: Dictionary.

Note that the TYPE= option setting is not case-sensitive. For example, the two option settings, TYPE='MyScore' and TYPE='myscore', are equivalent.

**BY Statement**

```plaintext
BY variables;
```

You can specify a BY statement with PROC SCORE to obtain separate scoring for observations in groups defined by the BY variables. You can also specify a BY statement to apply separate groups of scoring coefficients to the entire DATA= data set.

If your SCORE= input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the SCORE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

If the DATA= data set does not contain any of the BY variables, the entire DATA= data set is scored by each BY group of scoring coefficients in the SCORE= data set.

If the DATA= data set contains some but not all of the BY variables, or if some BY variables do not have the same type or length in the DATA= data set as in the SCORE= data set, then PROC SCORE prints an error message and stops.

If all the BY variables appear in the DATA= data set with the same type and length as in the SCORE= data set, then each BY group in the DATA= data set is scored using scoring coefficients from the corresponding BY group in the SCORE= data set. The BY groups in the DATA= data set must be in the same order as in the SCORE= data set. All BY groups in the DATA= data set must also appear in the SCORE= data set. If you do not specify the NOTSORTED option, some BY groups can appear in the SCORE= data set but not in the DATA= data set; such BY groups are not used in computing scores.
ID Statement

ID variables ;

The ID statement identifies variables from the DATA= data set to be included in the OUT= data set. If there is no ID statement, all variables from the DATA= data set are included in the OUT= data set. The ID variables can be character or numeric.

VAR Statement

VAR variables ;

The VAR statement specifies the variables to be used in computing scores. These variables must be in both the DATA= and SCORE= input data sets and must be numeric. If you do not specify a VAR statement, the procedure uses all numeric variables in the SCORE= data set. You should almost always specify a VAR statement with PROC SCORE because you would rarely use all the numeric variables in your data set to compute scores.

Details

Missing Values

If one of the scoring variables in the DATA= data set has a missing value for an observation, all the scores have missing values for that observation. The exception to this criterion is if the PREDICT option is specified, the variable with a coefficient of –1 can tolerate a missing value and still produce a prediction score. Also, a variable with a coefficient of 0 can tolerate a missing value.

If a scoring coefficient in the SCORE= data set has a missing value for an observation, the coefficient is not used in creating the new score variable for the observation. In other words, missing values of scoring coefficients are treated as zeros. This treatment affects only the observation in which the missing value occurs.

Regression Parameter Estimates from PROC REG

If the SCORE= data set is an OUTEST= data set produced by PROC REG and if you specify TYPE=PARMS, the interpretation of the new score variables depends on the PROC SCORE options chosen and the variables listed in the VAR statement. If the VAR statement contains only the independent variables used in a model in PROC REG, the new score variables give the predicted values. If the VAR statement contains the dependent variables and the independent variables used in a model in PROC REG, the interpretation of the new score variables depends on the PROC SCORE options chosen. If you omit both the PREDICT and the RESIDUAL options, the new score variables give negative residuals (PREDICT–ACTUAL). If you specify the RESIDUAL option, the new score variables give positive residuals (ACTUAL–PREDICT). If you specify the PREDICT option, the new score variables give predicted values.
Unless you specify the NOINT option for PROC REG, the OUTEST= data set contains the variable Intercept. The SCORE procedure uses the intercept value in computing the scores.

### Output Data Set

PROC SCORE produces an output data set but displays no output. The output OUT= data set contains the following:

- the ID variables, if any
- all variables from the DATA= data set, if no ID variables are specified
- the BY variables, if any
- the new score variables, named from the _NAME_ or _MODEL_ values in the SCORE= data set

### Computational Resources

Let

\[ v = \text{number of variables used in computing scores} \]
\[ s = \text{number of new score variables} \]
\[ b = \text{maximum number of new score variables in a BY group} \]
\[ n = \text{number of observations} \]

**Memory**

The array storage required is approximately \(8(4v + (3 + v)b + s) \) bytes. When you do not use BY processing, the array storage required is approximately \(8(4v + (4 + v)s) \) bytes.

**Time**

The time required to construct the scoring matrix is roughly proportional to \(vs\) and the time needed to compute the scores is roughly proportional to \(nus\).

### Examples

The following three examples use a subset of the Fitness data set. The complete data set is given in Chapter 61, “The REG Procedure.”
Example 64.1. Factor Scoring Coefficients

This example shows how to use PROC SCORE with factor scoring coefficients. First, the FACTOR procedure produces an output data set containing scoring coefficients in observations identified by _TYPE_="SCORE". These data, together with the original data set Fitness, are supplied to PROC SCORE, resulting in a data set containing scores Factor1 and Factor2. These statements produce Output 64.1.1 through Output 64.1.3:

```sas
/* This data set contains only the first 12 observations */
/* from the full data set used in the chapter on PROC REG. */
data Fitness;
   input Age Weight Oxygen RunTime RestPulse RunPulse @@;
datalines;
44  89.47  44.609  11.37  62  178  40  75.07  45.313  10.07  62  185
44  85.84  54.297  8.65  45  156  42  75.07  45.313  10.07  62  185
38  89.02  49.874  9.22  55  178  47  77.45  44.811  11.63  58  176
40  75.98  45.681 11.95  70  176  43  81.19  49.091  10.85  64  162

Output 64.1.2 lists the OUTSTAT= data set from PROC FACTOR. Note that observations 18 and 19 have _TYPE_='SCORE'. Observations 1 and 2 have _TYPE_='MEAN' and _TYPE_='STD', respectively. These four observations are used by PROC SCORE.
Since the PROC SCORE statement does not contain the NOSTD option, the data in the Fitness data set are standardized before scoring. For each variable specified in the VAR statement, the mean and standard deviation are obtained from the FactOut data set. For each observation in the Fitness data set, the variables are then standardized. For example, for observation 1 in the Fitness data set, the variable Age is standardized to \(0.5569 = \frac{(44 - 42.4167)}{2.8431}\).

After the data in the Fitness data set are standardized, the standardized values of the variables in the VAR statement are multiplied by the matching coefficients in the FactOut data set, and the resulting products are summed. This sum is output as a value of the new score variable.

Output 64.1.3 displays the FScore data set produced by PROC SCORE. This data set contains the variables Age, Weight, Oxygen, RunTime, RestPulse, and RunPulse from the Fitness data set. It also contains Factor1 and Factor2, the two new score variables.
Example 64.2. Regression Parameter Estimates

In this example, PROC REG computes regression parameter estimates for the Fitness data. (See Example 64.1 to create the Fitness data set.) The parameter estimates are output to a data set and used as scoring coefficients. For the first part of this example, PROC SCORE is used to score the Fitness data, which are the same data used in the regression.

In the second part of this example, PROC SCORE is used to score a new data set, Fitness2. For PROC SCORE, the TYPE= specification is PARMs, and the names of the score variables are found in the variable _MODEL_, which gets its values from the model label. The following code produces Output 64.2.1 through Output 64.2.3:

```sas
proc reg data=Fitness outest=RegOut;
OxyHat: model Oxygen=Age Weight RunTime RunPulse RestPulse;
    title 'REGRESSION SCORING EXAMPLE';
run;

proc print data=RegOut;
    title2 'OUTEST= Data Set from PROC REG';
run;

proc score data=Fitness score=RegOut out=RScoreP type=parms;
    var Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreP;
    title2 'Predicted Scores for Regression';
run;

proc score data=Fitness score=RegOut out=RScoreR type=parms;
```
var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreR;
   title2 'Negative Residual Scores for Regression';
run;

Output 64.2.1 shows the PROC REG output. The column labeled “Parameter Estimates” lists the parameter estimates. These estimates are output to the RegOut data set.

Output 64.2.1. Creating an OUTTEST= Data Set with PROC REG

<td>oxyhat</td>
<td>PARMS</td>
<td>Oxygen</td>
<td>2.53970</td>
<td>151.916</td>
<td>-0.63045</td>
</tr>
</tbody>
</table>

Output 64.2.3 lists the data sets created by PROC SCORE. Since the SCORE= data set does not contain observations with _TYPE_='MEAN' or _TYPE_='STD', the data in the Fitness data set are not standardized before scoring. The SCORE= data set contains the variable Intercept, so this intercept value is used in computing the score. To produce the RScoreP data set, the VAR statement in PROC SCORE includes only the independent variables from the model in PROC REG. As a result, the OxyHat variable contains predicted values. To produce the RScoreR data set, the VAR statement in PROC SCORE includes both the dependent variables and the independent variables from the model in PROC REG. As a result, the OxyHat variable contains negative residuals (PREDICT—ACTUAL). If the RESIDUAL option is specified, the variable OxyHat contains positive residuals (ACTUAL—PREDICT). If the PREDICT option is specified, the OxyHat variable contains predicted values.
Output 64.2.3. Predicted and Residual Scores from the OUT= Data Set Created by PROC SCORE and Reproduced Using PROC PRINT

PROC SCORE scores the Fitness2 data set using the parameter estimates in the RegOut data set. These parameter estimates result from fitting a regression equation to the Fitness data set. The NOSTD option is specified, so the raw data are not standardized before scoring. (However, the NOSTD option is not necessary here. The SCORE= data set does not contain observations with _TYPE_='MEAN' or _TYPE_='STD', so standardization is not performed.) The VAR statement contains the dependent variables and the independent variables used in PROC REG. In addition, the PREDICT option is specified. This combination gives predicted values for the new score variable. The name of the new score variable is OxyHat, from the value of the _MODEL_ variable in the SCORE= data set. Output 64.2.5 shows the data set produced by PROC SCORE.

Example 64.3. Custom Scoring Coefficients

This example uses a specially created custom scoring data set and produces Output 64.3.1. The first scoring coefficient creates a variable that is Age–Weight; the second scoring coefficient evaluates the variable RunPulse–RstPulse; and the third scoring coefficient totals all six variables. Since the scoring coefficients data set (data set A) does not contain any observations with _TYPE_=`MEAN` or _TYPE_=`STD`, the data in the Fitness data set (see Example 64.1) are not standardized before scoring.

```plaintext
data A;
  input _type_ $ _name_ $ Age Weight RunTime RunPulse RestPulse;
datalines;
SCORE AGE_WGT 1 -1 0 0 0
SCORE RUN_RST 0 0 0 1 -1
SCORE TOTAL 1 1 1 1 1
;
proc print data=A;
  title 'CONSTRUCTED SCORING EXAMPLE';
  title2 'Scoring Coefficients';
run;

proc score data=Fitness score=A out=B;
  var Age Weight RunTime RunPulse RestPulse;
run;
proc print data=B;
  title2 'Scored Data';
run;
```
Output 64.3.1. Custom Scoring Data Set and Scored Fitness Data: PROC PRINT

REFERENCES .......................................................... 4115
The SIM2D procedure produces a spatial simulation for a Gaussian random field with a specified mean and covariance structure in two dimensions using an LU decomposition technique.

The simulation can be conditional or unconditional. If it is conditional, a set of coordinates and associated field values are read from a SAS data set. The resulting simulation honors these data values.

You can specify the mean structure as a quadratic in the coordinates. You can specify the covariance by naming the form and supplying the associated parameters.

PROC SIM2D can handle anisotropic and nested semivariogram models. Three covariance models are supported: Gaussian, exponential, and spherical. A single nugget effect is also supported.

You can specify the locations of simulation points in a GRID statement or they can be read from a SAS data set. The grid specification is most suitable for a regular grid; the data set specification can handle any irregular pattern of points.

The SIM2D procedure writes the simulated values for each grid point to an output data set. The SIM2D procedure does not produce any displayed output.

Introduction to Spatial Simulation

The purpose of spatial simulation is to produce a set of partial realizations of a spatial random field \( Z(s), s \in D \subset \mathbb{R}^2 \) in a way that preserves a specified mean \( \mu(s) = E[Z(s)] \) and covariance structure \( C_z(s_1 - s_2) = \text{cov}(Z(s_1), Z(s_2)) \).

The realizations are partial in the sense that they occur only at a finite set of locations \( (s_1, s_2, \ldots, s_n) \). These locations are typically on a regular grid, but they can be arbitrary locations in the plane.

There are a number of different types of spatial simulation and associated computational methods. PROC SIM2D produces simulations for continuous processes in two dimensions. This means that the possible values of the measured quantity \( Z(s_0) \) at location \( s_0 = (x_0, y_0) \) can vary continuously over a certain range.

An additional assumption, needed for computational purposes, is that the spatial random field \( Z(s) \) is Gaussian.

Spatial simulation is different from spatial prediction, where the emphasis is on producing a point estimate at a given grid location. In this sense, spatial prediction is local. In contrast, spatial simulation is global; the emphasis is on the entire realization \( (Z(s_1), Z(s_2), \ldots, Z(s_n)) \).
Chapter 65. The SIM2D Procedure

Given the correct mean $\mu(s)$ and covariance structure $C_z(s_1 - s_2)$, SRF quantities that are difficult or impossible to calculate in a spatial prediction context can easily be approximated by repeated simulations.

**Getting Started**

Spatial simulation, just like spatial prediction, requires a model of spatial dependence, usually in terms of the covariance $C_z(h)$. For a given set of spatial data $Z(s_i), i = 1, \cdots, n$, the covariance structure (both the form and parameter values) can be found by the VARIOGRAM procedure. This example uses the coal seam thickness data that is also used in the “Getting Started” section of Chapter 80, “The VARIOGRAM Procedure.”

**Preliminary Spatial Data Analysis**

In this example, the data consist of coal seam thickness measurements (in feet) taken over an approximately square area. The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

It is instructive to see the locations of the measured points in the area where you want to perform spatial simulations. It is generally desirable to have these locations scattered evenly around the simulation area.

First, the data are input and the sample locations plotted.

```sas
proc gplot data=thick;
title 'Locations of Measured Samples';
plot north*east / frame cframe=ligr haxis=axis1
   vaxis=axis2;
symbol1 v=dot color=blue;
axis1 minor=none;
axis2 minor=none label=(angle=90 rotate=0);
label east = 'East'
   north = 'North'
;
run;
```

Figure 65.1. Locations of Measured Samples

```sas
proc g3d data=thick;
title 'Surface Plot of Coal Seam Thickness';
scatter east*north=thick / xticknum=5 yticknum=5
```

Figure 65.2 shows the small scale variation typical of spatial data, but there does not appear to be any surface trend. Hence, you can work with the original thickness data rather than residuals from a trend surface fit. In fact, a reasonable approximation of the spatial process generating the coal seam data is given by

\[ Z(s) = \mu + \varepsilon(s) \]

where the \( \varepsilon(s) \) is a Gaussian SRF with Gaussian covariance structure

\[ C_z(h) = c_0 \exp \left( -\frac{h^2}{a_0^2} \right) \]
Note that the term “Gaussian” is used in two ways in this description. For a set of locations \( s_1, s_2, \ldots, s_n \), the random vector

\[
Z(s) = \begin{bmatrix}
Z(s_1) \\
Z(s_2) \\
\vdots \\
Z(s_n)
\end{bmatrix}
\]

has a multivariate Gaussian or normal distribution \( N_n(\mu, \Sigma) \). The \((i,j)\)th element of \( \Sigma \) is computed by \( C_z(s_i - s_j) \), which happens to be a Gaussian functional form. Any functional form for \( C_z(h) \) yielding a valid covariance matrix \( \Sigma \) can be used. Both the functional form of \( C_z(h) \) and the parameter values

\[
\mu = 40.14 \\
c_0 = 7.5 \\
a_0 = 30.0
\]

are visually estimated using PROC VARIOGRAM, a DATA step, and the GPLOT procedure. Refer to the “Getting Started” section beginning on page 4852 in the chapter on the VARIOGRAM procedure for details on how these parameter values are obtained.

The choice of a Gaussian functional form for \( C_z(h) \) is simply based on the data, and it is not at all crucial to the simulation. However, it is crucial to the simulation method used in PROC SIM2D that \( Z(s) \) be a Gaussian SRF. For details, see the section “Computational and Theoretical Details of Spatial Simulation” beginning on page 4106.

**Investigating Variability by Simulation**

The variability of \( Z(s) \), modeled by

\[
Z(s) = \mu + \varepsilon(s)
\]

with the Gaussian covariance structure \( C_z(h) \) found previously is not obvious from the covariance model form and parameters. The variation around the mean of the surface is relatively small, making it difficult visually to pick up differences in surface plots of simulated realizations. Instead, you investigate variations at selected grid points.

To do this investigation, this example uses PROC SIM2D and specifies the Gaussian model with the parameters found previously. Five thousand simulations (iterations) are performed on two points: the extreme south-west point of the region and a point towards the north-east corner of the region. Because of the irregular nature of these points, a GDATA= data set is produced with the coordinates of the selected points.

Summary statistics are computed for each of these grid points by using a BY statement in PROC UNIVARIATE.

Figure 65.4. Simulation Statistics at Grid Point (XC=75, YC=75)

Syntax

The following statements are available in PROC SIM2D.

```
PROC SIM2D options;
   COORDINATES coordinate-variables;
   GRID grid-options;
   SIMULATE simulate-options;
   MEAN mean-options;
```
The SIMULATE and MEAN statements are hierarchical; you can specify any number of SIMULATE statements, but you must specify at least one. If you specify a MEAN statement, it refers to the preceding SIMULATE statement. If you do not specify a MEAN statement, a zero mean model is simulated.

You must specify a single COORDINATES statement to identify the x and y coordinate variables in the input data set when you perform a conditional simulation. You must also specify a single GRID statement to specify the grid information.

The following table outlines the options available in PROC SIM2D classified by function.

<table>
<thead>

PROC SIM2D Statement

PROC SIM2D options ;

DATA=SAS-data-set

specifies a SAS data set containing the x and y coordinate variables and the SIMULATE VAR= variables. This data set is required if any of the SIMULATE statements are conditional, that is, if you specify the VAR= option. If none of the SIMULATE statements are conditional then you do not need the DATA= option, and this option is ignored if you specify it.

NARROW

restricts the variables included in the OUTSIM= data set. When you specify the NARROW option, only four variables are included. This option is useful when a large number of simulations are produced. Including only four variables reduces the memory required for the OUTSIM= data set. For details on the variables that are excluded with the NARROW option, see the section “Output Data Set” on page 4110.

OUTSIM=SAS-data-set

specifies a SAS data set to store the simulation values, iteration number, simulate statement label, variable name, and grid location. For details, see the section “Output Data Set” on page 4110.

COORDINATES Statement

COORDINATES coordinate-variables ;

The following two options give the name of the variables in the DATA= data set containing the values of the x and y coordinates of the conditioning data.

Only one COORDINATES statement is allowed, and it is applied to all SIMULATE statements that have a VAR= specification. In other words, it is assumed that all the VAR= variables in all SIMULATE statements have the same x and y coordinates.
You can abbreviate the COORDINATES statement as COORD.

\[
\begin{align*}
\text{COORD} & = (\text{variable-name}) \\
\text{XC} & = (\text{variable-name}) \\
\text{gives the name of the variable containing the } x \text{ coordinate of the data in the DATA=} \\
\text{data set.} \\
\text{COORD} & = (\text{variable-name}) \\
\text{YC} & = (\text{variable-name}) \\
\text{gives the name of the variable containing the } y \text{ coordinate of the data locations in the} \\
\text{DATA=} \text{ data set.}
\end{align*}
\]

**GRID Statement**

\[
\begin{align*}
\text{GRID} & \quad \text{grid-options ;} \\
\text{The following options can be used to specify the grid of spatial locations at which to} \\
\text{perform the simulations. A single GRID statement is required and is applied to all} \\
\text{SIMULATE statements.}
\end{align*}
\]

There are two basic methods for specifying the grid. You can specify the \( x \) and \( y \) coordinates explicitly, or they can be read from a SAS data set. The options for the explicit specification of grid locations are as follows.

\[
\begin{align*}
\text{X} & = \text{number} \\
\text{X} & = x_1, \ldots, x_m \\
\text{X} & = x_1 \text{ to } x_m \\
\text{X} & = x_1 \text{ to } x_m \text{ by } \delta x \\
\text{specifies the } x \text{ coordinate of the grid locations.}
\end{align*}
\]

\[
\begin{align*}
\text{Y} & = \text{number} \\
\text{Y} & = y_1, \ldots, y_m \\
\text{Y} & = y_1 \text{ to } y_m \\
\text{Y} & = y_1 \text{ to } y_m \text{ by } \delta y \\
\text{specifies the } y \text{ coordinate of the grid locations.}
\end{align*}
\]

For example, the following two GRID statements are equivalent:

\[
\begin{align*}
\text{grid } & \ x=1,2,3,4,5 \quad y=0,2,4,6,8,10; \\
\text{grid } & \ x=1 \text{ to } 5 \quad y=0 \text{ to } 10 \text{ by } 2;
\end{align*}
\]

To specify grid locations from a SAS data set, you must provide the name of the data set and the variables containing the values of the \( x \) and \( y \) coordinates.

\[
\begin{align*}
\text{GRIDDATA} & = \text{SAS-data-set} \\
\text{GDATA} & = \text{SAS-data-set} \\
\text{specifies a SAS data set containing the } x \text{ and } y \text{ grid coordinates.}
\end{align*}
\]
**XCOORD=(variable-name)**
**XC=(variable-name)**

gives the name of the variable containing the $x$ coordinate of the grid locations in the GRIDDATA= data set.

**YCOORD=(variable-name)**
**YC=(variable-name)**

gives the name of the variable containing the $y$ coordinate of the grid locations in the GRIDDATA= data set.

---

**SIMULATE Statement**

```markdown
SIMULATE simulate-options ;
```

The SIMULATE statement specifies details on the simulation and the covariance model used in the simulation. You can specify the following options with a SIMULATE statement, which can be abbreviated by SIM.

**NUMREAL=number**
**NUMR=number**
**NR=number**

specifies the number of realizations to produce for the spatial process specified by the covariance model. Note that the number of observations in the OUTSIM= data set contributed by a given SIMULATE statement is the product of the NUMREAL= value with the number of grid points. This can cause the OUTSIM= data set to become large even for moderate values of the NUMREAL= option.

**VAR= (variable-name)**

specifies the single numeric variable used as the conditioning variable in the simulation. In other words, the simulation is conditional on the values of the VAR= variable found in the DATA= data set. If you omit the VAR= option, the simulation is unconditional. Since multiple SIMULATE statements are allowed, you can perform both unconditional and conditional simulations with a single PROC SIM2D statement.

---

**Covariance Model Specification**

There are two ways to specify a semivariogram or covariance model. In the first method, you can specify the required parameters SCALE, RANGE, and FORM, and possibly the optional parameters NUGGET, ANGLE, and RATIO, explicitly in the SIMULATE statement.

In the second method, you can specify an MDATA= data set. This data set contains variables corresponding to the required SCALE, RANGE, and FORM parameters, and, optionally, variables for the NUGGET, ANGLE, and RATIO parameters.

The two methods are exclusive; either you specify all parameters explicitly, or they are all are read from the MDATA= data set.
\textbf{ANGLE}=angle
\textbf{ANGLE}=(angle_1,\ldots,angle_k)

specifies the angle of the major axis for anisotropic models, measured in degrees clockwise from the N-S axis. In the case of a nested semivariogram model, you can specify an angle for each nesting. The default is ANGLE=0.

\textbf{FORM}=form\_spec
\textbf{FORM}=(form\_spec_1, form\_spec_2,\ldots,form\_spec_k)

specifies the functional form or forms of the semivariogram model, where \textit{form\_spec} can take only the values SPHERICAL, EXPONENTIAL, and GAUSSIAN. The two ways of specifying the FORM\= parameter allows specification of both nested and nonnested models. The following abbreviations are permitted. For the spherical model, you can specify the \textit{form\_spec} as FORM=SPHERICAL, FORM=SPH, or FORM=S. For the exponential model, you can specify the \textit{form\_spec} as FORM=EXPONENTIAL, FORM=EXP, or FORM=E. For the Gaussian model, you can specify the \textit{form\_spec} as FORM=GAUSSIAN, FORM=GAUSS, or FORM=G.

\textbf{MDATA}=SAS-data-set

specifies the input data set that contains parameter values for the covariance or semivariogram model. The MDATA= data set must contain variables named SCALE, RANGE, and FORM, and it can optionally contain the variables NUGGET, ANGLE, and RATIO.

The FORM variables must be character, and they can assume the same values allowed in the explicit FORM\= syntax described previously. The RANGE and SCALE variables must be numeric. The optional variables ANGLE, RATIO, and NUGGET must also be numeric if present.

The number of observations present in the MDATA= data set corresponds to the level of nesting of the covariance or semivariogram model. For example, to specify a nonnested model using a spherical covariance, an MDATA= data set might look like the following.

\begin{verbatim}
data md1;
  input scale range form $;
datalines;
  25 10 sph
run;
\end{verbatim}

The PROC SIM2D statement to use the MDATA\= specification is of the form

\begin{verbatim}
proc sim2d data=...;
  sim var=.... mdata=md1;
run;
\end{verbatim}

This is equivalent to the following explicit specification of the covariance model parameters:

\begin{verbatim}
proc sim2d data=...;
  sim var=.... scale=25 range=10 form=sph;
run;
\end{verbatim}
The following MDATA= data set is an example of an anisotropic nested model:

```plaintext
data md2;
  input scale range form $ nugget angle ratio;
datalines;
  20 8 S 5 35 .7
  12 3 G 5 0 .8
  4 1 G 5 45 .5
;
proc sim2d data=...;
  sim var=.... mdata=md2;
run;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```plaintext
proc sim2d data=...;
  sim var=.... scale=(20,12,4) range=(8,3,1) form=(S,G,G)
  angle=(35,0,45) ratio=(.7,.8,.5) nugget=5;
run;
```

This example is somewhat artificial in that it is usually hard to detect different anisotropy directions and ratios for different nestings using an experimental semivariogram. Note that the NUGGET value is the same for all nestings. This is always the case; the nugget effect is a single additive term for all models. For further details, refer to the section “The Nugget Effect” on page 2051 in Chapter 37, “The KRIGE2D Procedure.”

The SIMULATE statement can be given a label. This is useful for identification in the OUTSIM= data set when multiple SIMULATE statements are specified.

For example,

```plaintext
proc sim2d data=...;
  gauss1: sim var=.... form=gauss;
  mean ....;
  gauss2: sim var=.... form=gauss;
  mean ....;
  exp1: sim var=.... form=exp;
  mean ....;
  exp2: sim var=.... form=exp;
  mean ....;
run;
```

In the OUTSIM= data set, the values ’GAUSS1’, ’GAUSS2’, ’EXP1’, and ’EXP2’ for the LABEL variable help to identify the realizations corresponding to the four SIMULATE statements. If you do not provide a label for a SIMULATE statement, a default label of SIMn is given, where n is the number of unlabeled SIMULATE statements seen so far.
**NUGGET=** number

specifies the nugget effect for the model. This effect is due to a discontinuity in
the semivariogram as determined by plotting the sample semivariogram (refer to the
section “The Nugget Effect” on page 2051 in the chapter on the KRIGE2D procedure
for details). For models without any nugget effect, the NUGGET= option is left out.
The default is NUGGET=0.

**RANGE=** range

**RANGE=** (range<sub>1</sub>, . . . , range<sub>k</sub>)

specifies the range parameter in the semivariogram models. In the case of a nested
semivariogram model, you must specify a range for each nesting.

The range parameter is the divisor in the exponent in all supported models. It has
the units of distance or distance squared for these models, and it is related to the
correlation scale for the underlying spatial process. Refer to the section “Theoretical
Semivariogram Models” beginning on page 2045 in the chapter on the KRIGE2D
procedure for details on how the RANGE= values are determined.

**RATIO=** ratio

**RATIO=** (ratio<sub>1</sub>, . . . , ratio<sub>k</sub>)

specifies the ratio of the length of the minor axis to the length of the major axis for
anisotropic models. The value of the RATIO= option must be between 0 and 1. In
the case of a nested semivariogram model, you can specify a ratio for each nesting.
The default is RATIO=1.

**SCALE=** scale

**SCALE=** (scale<sub>1</sub>, . . . , scale<sub>k</sub>)

specifies the scale parameter in semivariogram models. In the case of a nested semi-
variogram model, you must specify a scale for each nesting.

The scale parameter is the multiplicative factor in all supported models; it has the
same units as the variance of the VAR= variable. Refer to the section “Theoretical
Semivariogram Models” beginning on page 2045 in the chapter on the KRIGE2D
procedure for details on how the SCALE= values are determined.

**SEED=** seed value

specifies the seed to use for the random number generator. If you omit the SEED= value, the system clock is used.

**SINGULAR=** number

gives the singularity criteria for solving the set of linear equations involved in the
computation of the mean and covariance of the conditional distribution associated
with a given SIMULATE statement. The larger the value of the SINGULAR= option,
the easier it is for the covariance matrix system to be declared singular. The default is
SINGULAR=1E-8. For more details on the use of the SINGULAR= option, see the
section “Computational and Theoretical Details of Spatial Simulation” beginning on
page 4106.
A mean function \( \mu(s) \) that is a quadratic in the coordinates can be written

\[
\mu(s) = \mu(x, y) = \beta_0 + \beta_1 x + \beta_2 y + \beta_3 x^2 + \beta_4 y^2 + \beta_5 x y
\]

The MEAN statement is used to specify the quadratic surface to use as the mean function for the simulated SRF. There are three ways to specify the MEAN statement. The MEAN statement allows the specification of the coefficients \( \beta_0, \cdots, \beta_5 \) either explicitly or through a QDATA= data set.

An example of an explicit specification is

\[
\text{mean } 1.4 + 2.5 x + 3.6 y + 0.47 x^2 + 0.58 y^2 + 0.69 x y;
\]

In this example, all terms have a nonzero coefficient. Any term with a zero coefficient is simply left out of the specification. For example,

\[
\text{mean } 1.4;
\]

is a valid quadratic form with all terms having zero coefficients except the constant term.

An equivalent way of specifying the mean function is through the QDATA= data set. For example, the following MEAN statement

\[
\text{mean } 1.4 + 2.5 x + 3.6 y + 0.47 x^2 + 0.58 y^2 + 0.69 x y;
\]

can be alternatively specified by the following DATA step and MEAN statement:

```plaintext
data q1;
  input c1 c2 c3 c4 c5 c6;
datalines;
  1.4 2.5 3.6 0.47 0.58 0.69
run;
proc sim2d data=....;
simulate ...;
  mean qdata=q1 const=c1 cx=c2 cy=c3 cxx=c4 cyy=c5 cxy=c6;
run;
```
The QDATA= data set specifies the data set containing the coefficients. The parameters CONST=, CX=, CY=, CXX=, CYY=, and CYX= specify the variables in the QDATA= data set that correspond to the constant, linear x, linear y, and so on. For any coefficient not specified in this list, the QDATA= data set is checked for the presence of variables with default names of CONST, CX, CY, CXX, CYY, and CYX. If these variables are present, their values are taken as the corresponding coefficients. Hence, you can rewrite the previous example as

```plaintext
data q1;
  input const cx cy cxx cyy cxy;
datalines;
  1.4 2.5 3.6 .47 .58 .69;
proc sim2d data=....;
  simulate ....;
  mean qdata=q1;
run;
```

If a given coefficient does not appear in the list or in the data set with the default name, a value of zero is assumed.

## Details

### Computational and Theoretical Details of Spatial Simulation

#### Introduction

There are a number of approaches to simulating spatial random fields or, more generally, simulating sets of dependent random variables. This includes sequential indicator methods, turning bands, and the Karhunen-Loève Expansion. Refer to Christakos (1992, Chapter 8) and Duetsch and Journel (1992, Chapter V) for details.

A particularly simple method available for Gaussian spatial random fields is the LU decomposition method. This method is computationally efficient. For a given covariance matrix, the \( LU = L L^T \) decomposition is computed once, and the simulation proceeds by repeatedly generating a vector of independent \( N(0,1) \) random variables and multiplying by the \( L \) matrix.

One problem with this technique is memory requirements; memory is required to hold the full data and grid covariance matrix in core. While this is especially limiting in the three-dimensional case, you can use PROC SIM2D, which handles only two-dimensional data, for moderately sized simulation problems.

#### Theoretical Development

It is a simple matter to produce an \( N(0,1) \) random number, and by stacking \( k \) \( N(0,1) \) random numbers in a column vector, you can obtain a vector with independent standard normal components \( W \sim N_k(0, I) \). The meaning of the terms independence and randomness in the context of a deterministic algorithm required for the generation of these numbers is a little subtle; refer to Knuth (1981, Vol. 2, Chapter 3) for details.
Rather than $W \sim N_k(0, I)$, what is required is the generation of a vector $Z \sim N_k(0, C)$, that is,

$$Z = \begin{bmatrix} Z_1 \\ Z_2 \\ \vdots \\ Z_k \end{bmatrix}$$

with covariance matrix

$$C = \begin{pmatrix} C_{11} & C_{12} & \cdots & C_{1k} \\ C_{21} & C_{22} & \cdots & C_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ C_{k1} & C_{k2} & \cdots & C_{kk} \end{pmatrix}$$

If the covariance matrix is symmetric and positive definite, it has a Cholesky root $L$ such that $C$ can be factored as

$$C = LL^T$$

where $L$ is lower triangular. Refer to Ralston and Rabinowitz (1978, Chapter 9, Section 3-3) for details. This vector $Z$ can be generated by the transformation $Z = LW$. Note that this is where the assumption of a Gaussian SRF is crucial. When $W \sim N_k(0, I)$, then $Z = LW$ is also Gaussian. The mean of $Z$ is

$$E(Z) = L(E(W)) = 0$$

and the variance is

$$\text{Var}(Z) = \text{Var}(LW) = E(LWW^TL^T) = LE(WW^T)L^T = LL^T = C$$

Consider now an SRF $Z(s), s \in D \subset \mathbb{R}^2$, with spatial covariance function $C(h)$. Fix locations $s_1, s_2, \cdots, s_k$, and let $Z$ denote the random vector

$$Z = \begin{bmatrix} Z(s_1) \\ Z(s_2) \\ \vdots \\ Z(s_k) \end{bmatrix}$$

with corresponding covariance matrix

$$C_z = \begin{pmatrix} C(0) & C(s_1 - s_2) & \cdots & C(s_1 - s_k) \\ C(s_2 - s_1) & C(0) & \cdots & C(s_2 - s_k) \\ \vdots & \vdots & \ddots & \vdots \\ C(s_k - s_1) & C(s_k - s_2) & \cdots & C(0) \end{pmatrix}$$
Since this covariance matrix is symmetric and positive definite, it has a Cholesky root, and the $Z(s_i), i = 1, \ldots, k$ can be simulated as described previously. This is how the SIM2D procedure implements unconditional simulation in the zero mean case. More generally,

$$Z(s) = \mu(s) + \varepsilon(s)$$

with $\mu(s)$ being a quadratic form in the coordinates $s = (x, y)$, and the $\varepsilon(s)$ being an SRF having the same covariance matrix $C_Z$ as previously. In this case, the $\mu(s_i), i = 1, \ldots, k$ is computed once and added to the simulated vector $\varepsilon(s_i), i = 1, \ldots, k$ for each realization.

For a conditional simulation, this distribution of

$$Z = \begin{bmatrix} Z(s_1) \\ Z(s_2) \\ \vdots \\ Z(s_k) \end{bmatrix}$$

must be conditioned on the observed data. The relevant general result concerning conditional distributions of multivariate normal random variables is the following. Let $X \sim N_m(\mu, \Sigma)$, where

$$X = \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}$$

$$\mu = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}$$

and

$$\Sigma = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{pmatrix}$$

The subvector $X_1$ is $k \times 1$, $X_2$ is $n \times 1$, $\Sigma_{11}$ is $k \times k$, $\Sigma_{22}$ is $n \times n$, and $\Sigma_{12} = \Sigma_{21}^T$ is $k \times n$, with $k + n = m$. The full vector $X$ is partitioned into two subvectors $X_1$ and $X_2$, and $\Sigma$ is similarly partitioned into covariances and cross covariances.

With this notation, the distribution of $X_1$ conditioned on $X_2 = x_2$ is $N_k(\tilde{\mu}, \tilde{\Sigma})$, with

$$\tilde{\mu} = \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2)$$

and

$$\tilde{\Sigma} = \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}.$$
Refer to Searle (1971, pp. 46–47) for details. The correspondence with the conditional spatial simulation problem is as follows. Let the coordinates of the observed data points be denoted \( \tilde{s}_1, \tilde{s}_2, \cdots, \tilde{s}_n \), with values \( \tilde{z}_1, \tilde{z}_2, \cdots, \tilde{z}_n \). Let \( \tilde{Z} \) denote the random vector

\[
\tilde{Z} = \begin{bmatrix}
Z(\tilde{s}_1) \\
Z(\tilde{s}_2) \\
\vdots \\
Z(\tilde{s}_n)
\end{bmatrix}
\]

The random vector \( \tilde{Z} \) corresponds to \( X_2 \), while \( Z \) corresponds to \( X_1 \). Then \( (Z \mid \tilde{Z} = \tilde{z}) \sim N_k(\tilde{\mu}, \tilde{C}) \) as in the previous distribution. The matrix \( \tilde{C} = C_{11} - C_{12}C_{22}^{-1}C_{21} \)

is again positive definite, so a Cholesky factorization can be performed.

The dimension \( n \) for \( \tilde{Z} \) is simply the number of nonmissing observations for the \( \text{VAR=} \) variable; the values \( \tilde{z}_1, \tilde{z}_2, \cdots, \tilde{z}_n \) are the values of this variable. The coordinates \( \tilde{s}_1, \tilde{s}_2, \cdots, \tilde{s}_n \) are also found in the \( \text{DATA=} \) data set, with the variables corresponding to the \( x \) and \( y \) coordinates identified in the \( \text{COORDINATES} \) statement. Note that all \( \text{VAR=} \) variables use the same set of conditioning coordinates; this fixes the matrix \( C_{22} \) for all simulations.

The dimension \( k \) for \( Z \) is the number of grid points specified in the \( \text{GRID} \) statement. Since there is a single \( \text{GRID} \) statement, this fixes the matrix \( C_{11} \) for all simulations. Similarly, \( C_{12} \) is fixed.

The Cholesky factorization \( \tilde{C} = LL^T \) is computed once, as is the mean correction

\[
\tilde{\mu} = \mu_1 + C_{12}C_{22}^{-1}(x_2 - \mu_2)
\]

Note that the means \( \mu_1 \) and \( \mu_2 \) are computed using the grid coordinates \( s_1, s_2, \cdots, s_k \), the data coordinates \( \tilde{s}_1, \tilde{s}_2, \cdots, \tilde{s}_n \), and the quadratic form specification from the \( \text{MEAN} \) statement. The simulation is now performed exactly as in the unconditional case. A \( k \times 1 \) vector of independent standard \( N(0, 1) \) random variables is generated and multiplied by \( L \), and \( \tilde{\mu} \) is added to the transformed vector. This is repeated \( N \) times, where \( N \) is the value specified for the \( \text{NR=} \) option.

**Computational Details**

In the computation of \( \tilde{\mu} \) and \( \Sigma \) described in the previous section, the inverse \( \Sigma_{22}^{-1} \) is never actually computed; an equation of the form

\[
\Sigma_{22}A = B
\]

is solved for \( A \) using a modified Gaussian elimination algorithm that takes advantage of the fact that \( \Sigma_{22} \) is symmetric with constant diagonal \( C_z(0) \) that is larger than all off-diagonal elements. The \( \text{SINGULAR=} \) option pertains to this algorithm. The value specified for the \( \text{SINGULAR=} \) option is scaled by \( C_z(0) \) before comparison with the pivot element.
Memory Usage

For conditional simulations, the largest matrix held in core at any one time depends on the number of grid points and data points. Using the previous notation, the data-data covariance matrix $C_{22}$ is $n \times n$, where $n$ is the number of nonmissing observations for the VAR= variable in the DATA= data set. The grid-data cross covariance $C_{12}$ is $n \times k$, where $k$ is the number of grid points. The grid-grid covariance $C_{11}$ is $k \times k$. The maximum memory required at any one time for storing these matrices is

$$\max (k(k + 1), n(n + 1) + 2(n \times k)) \times \text{sizeof(double)}$$

There are additional memory requirements that add to the total memory usage, but usually these matrix calculations dominate, especially when the number of grid points is large.

Output Data Set

The SIM2D procedure produces a single output data set: the OUTSIM=SAS-data-set. The OUTSIM= data set contains all the needed information to uniquely identify the simulated values.

The OUTSIM= data set contains the following variables:

- **LABEL**, which is the label for the current SIMULATE statement
- **VARNAME**, which is the name of the conditioning variable for the current SIMULATE statement
- **_ITER_**, which is the iteration number within the current SIMULATE statement
- **GXC**, which is the x-coordinate for the current grid point
- **GYC**, which is the y-coordinate for the current grid point
- **SVALUE**, which is the value of the simulated variable

If you specify the NARROW option in the PROC SIM2D statement, the LABEL and VARNAME variables are not included in the OUTSIM= data set. This option is useful in the case where the number of data points, grid points, and realizations are such that they generate a very large OUTSIM= data set. The size of the OUTSIM= data set is reduced when these variables are not included.

In the case of an unconditional simulation, the VARNAME variable is not included. In the case of mixed conditional and unconditional simulations (that is, when multiple SIMULATE statements are specified and one or more contain a VAR= specification and one or more do not contain a VAR= specification), the VARNAME variable is included but is given a missing value for those observations corresponding to an unconditional simulation.
Example 65.1. Simulation

Continuing with the coal seam thickness example from the “Getting Started” section beginning on page 4092, this example asks a more complicated question. This question is economic in nature, and the (approximate) answer requires the use of simulation.

Simulating a Subregion for Economic Feasibility

The coal seam must be of a minimum thickness, called a cutoff value, for a mining operation to be profitable. Suppose that, for a subregion of the measured area, the cost of mining is higher than the remaining areas due to the geology of the overburden. This higher cost results in a higher thickness cutoff value for the subregion. Suppose also that it is determined from a detailed cost analysis that at least 60 percent of the subregion must exceed a seam thickness of 39.7 feet for profitability.

How can you use the SRF model ($\mu$ and $C_z(s)$) and the measured seam thickness values $Z(s_i), i = 1, \ldots, 75$ to determine, in some approximate way, if at least 60 percent of the subregion exceeds this minimum?

Spatial prediction does not appear to be helpful in answering this question. While it is easy to determine if a predicted value at a location in the subregion is above the 39.7 feet cutoff value, it is not clear how to incorporate the standard error associated with the predicted value. The standard error is what characterizes the stochastic nature of the prediction (and the underlying SRF). It is clear that it must be included in any realistic approach to the problem.

A conditional simulation, on the other hand, seems to be a natural way of obtaining an approximate answer. By simulating the SRF on a sufficiently fine grid in the subregion, you can determine the proportion of grid points in which the mean value over realizations exceeds the 39.7 feet cutoff and compare it with the 60 percent value needed for profitability.

It is desirable in any simulation study that the quantity being estimated (in this case, the proportion exceeding the 39.7 feet cutoff) not depend on the number of simulations performed. For example, suppose that the maximum seam thickness is simulated. It is likely that the maximum value increases as the number of simulations performed increases. Hence, a simulation is not useful for such an estimate. A simulation is useful for determining the distribution of the maximum, but there are general theoretical results for such distributions, making such a simulation unnecessary. Refer to Leadbetter, Lindgren, and Rootzen (1983) for details.

In the case of simulating the proportion exceeding the 39.7 feet cutoff, it is expected that this quantity will settle down to a fixed value as the number of realizations increases. At a fixed grid point, the quantity being compared with the cutoff value is the mean over all simulated realizations; this mean value settles down to a fixed number as the number of realizations increases. In the same manner, the proportion of the grid where the mean values exceed the cutoff also becomes constant. This can be tested using PROC SIM2D.
A crucial, nonprovable assumption in applying SRF theory to the coal seam thickness data is that the values \( Z(s_i), i = 1, \ldots, 75 \) represent a single realization from the set of all possible realizations consistent with the SRF model \((\mu, C_z(h))\). A conditional simulation repeatedly produces other possible simulated realizations consistent with the model and data. However, the only concern of the mining company is with this single unique realization. It is not concerned with similar coal fields to be mined sometime in the future; it may never see another coal field remotely similar to this one, or it may not be in business in the future.

Hence the proportion found by generating repeated simulated realizations must somehow relate back to the unique realization that is the coal field (seam thickness). This is done by interpreting the proportion found from a simulation to the spatial mean proportion for the unique realization. The term “spatial mean” is simply an appropriate integral over the fixed (but unknown) spatial function \( z(s) \). (The SRF is denoted \( Z(s) \); a particular realization, a deterministic function of the spatial coordinates, is denoted \( z(s) \).

This interpretation requires an ergodic assumption, which is also needed in the original estimation of \( C_z(s) \). Refer to Cressie (1993, pp. 53–58) for a discussion of ergodicity and Gaussian SRFs.

**Implementation Using PROC SIM2D**

The subregion to be considered is the southeast corner of the field, which is a square region with length 40 distance units (in thousands of feet). PROC SIM2D is run on the entire data set for conditioning, while the simulation grid covers only this subregion. It is convenient to be able to vary the seed, the grid increment, and the number of simulations performed. The following macro implements the computation of the percent area exceeding the cutoff value by using the seed, the grid increment, and the number of simulated realizations as macro arguments.

The data set produced by PROC SIM2D is transposed so that each grid location is a separate variable. The MEANS procedure is then used to average the simulated value at each grid point over all realizations. It is this average that is compared to the cutoff value. The last DATA step does the comparison and determines the percent of the grid locations that exceed this cutoff value and writes the results to the listing file in the form of a report.

The macro is first invoked with a relatively coarse grid (grid increment of 10 distance units) and a small number of realizations (5). The next invocation uses a finer grid and 50 realizations, and the final invocation uses the same grid increment and 500 realizations. Each time, the macro is invoked with a different seed. The simulations indicate that around 87 percent of the subregion exceeds the cutoff value.

The number of grid points in the simulation increases with the square of the decrease in the grid increment, leading to long CPU processing times. Increasing the number of realizations results in a linear increase in processing times. Hence, using as coarse a grid as possible allows more realizations and experimentation with different seeds.

Chapter 66
The STDIZE Procedure

Overview

The STDIZE procedure standardizes one or more numeric variables in a SAS data set by subtracting a location measure and dividing by a scale measure. A variety of location and scale measures are provided, including estimates that are resistant to outliers and clustering. Some of the well-known standardization methods such as mean, median, std, range, Huber’s estimate, Tukey’s biweight estimate, and Andrew’s wave estimate are available in the STDIZE procedure.

In addition, you can multiply each standardized value by a constant and add a constant. Thus, the final output value is

\[
result = add + multiply \times \frac{\text{original} - \text{location}}{\text{scale}}
\]

where
- result = final output value
- add = constant to add (ADD= option)
- multiply = constant to multiply by (MULT= option)
- original = original input value
- location = location measure
- scale = scale measure

PROC STDIZE can also find quantiles in one pass of the data, a capability that is especially useful for very large data sets. With such data sets, the UNIVARIATE procedure may have high or excessive memory or time requirements.

Getting Started

The following example demonstrates how you can use the STDIZE procedure to obtain location and scale measures of your data.

In the following hypothetical data set, a random sample of grade 12 students is selected from a number of co-educational schools. Each school is classified as one of two types: Urban or Rural. There are 40 observations.

The variables are id (student identification), Type (type of school attended: ‘urban’=urban area and ‘rural’=rural area), and total (total assessment scores in History, Geometry, and Chemistry).

The following DATA step creates the SAS data set TotalScores.
data TotalScores;
  title 'High School Scores Data';
  input id Type $ total;
  datalines;
  1 rural 135
  2 rural 125
  3 rural 223
  4 rural 224
  5 rural 133
  6 rural 253
  7 rural 144
  8 rural 193
  9 rural 152
 10 rural 178
 11 rural 120
 12 rural 180
 13 rural 154
 14 rural 184
 15 rural 187
 16 rural 111
 17 rural 190
 18 rural 128
 19 rural 110
 20 rural 217
 21 urban 192
 22 urban 186
 23 urban 64
 24 urban 159
 25 urban 133
 26 urban 163
 27 urban 130
 28 urban 163
 29 urban 189
 30 urban 144
 31 urban 154
 32 urban 198
 33 urban 150
 34 urban 151
 35 urban 152
 36 urban 151
 37 urban 127
 38 urban 167
 39 urban 170
 40 urban 123
;
run;
Suppose you would now like to standardize the total scores in different types of schools prior to any further analysis. Before standardizing the total scores, you can use the Schematic Plots from PROC UNIVARIATE to summarize the total scores for both types of schools.

``` Sas
proc univariate data=TotalScores plot;
   var total;
   by Type;
run;
```

The PLOT option in the PROC UNIVARIATE statement creates the Schematic Plots and several other types of plots. The Schematic Plots display side-by-side box plots for each BY group (Figure 66.1). The vertical axis represents the total scores, and the horizontal axis displays two box plots: the one on the left is for the rural scores and the one on the right is for the urban scores.
Figure 66.1.  Schematic Plots from PROC UNIVARIATE
Inspection reveals that one urban score is a low outlier. Also, if you compare the lengths of two boxplots, there seems to be twice as much dispersion for the rural scores as for the urban scores.

**Figure 66.2.** Table for Extreme Observations When Type=urban

**Figure 66.2** displays the table from PROC UNIVARIATE for the lowest and highest five total scores for urban schools. The outlier (Obs = 3), marked in **Figure 66.1** by the symbol ‘0’, has a score of 64.

The following statements use the traditional standardization method (METHOD=STD) to compute the location and scale measures:

```plaintext
proc stdize data=totalscores method=std pstat;
  title2 'METHOD=STD';
  var total;
  by Type;
run;
```
Figure 66.3. Location and Scale Measures Table When METHOD=STD

Figure 66.3 displays the table of location and scale measures from the PROC STDIZE statement. PROC STDIZE uses the mean as the location measure and the standard deviation as the scale measure for standardizing. The PSTAT option displays this table; otherwise, no display is created.

The ratio of the scale of rural scores to the scale of urban scores is approximately 1.4 (41.96/30.07). This ratio is smaller than the dispersion ratio observed in the previous Schematic Plots.

The STDIZE procedure provides several location and scale measures that are resistant to outliers. The following statements invoke three different standardization methods and display the Location and Scale Measures tables:

```markdown
proc stdize data=totalscores method=mad pstat;
   title2 'METHOD=MAD';
   var total;
   by Type;
run;
```
The results from this analysis are displayed in the following figures.

<table>
<thead>
<tr>
<th>High School Scores Data METHOD=MAD</th>

<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Figure 66.4. Location and Scale Measures Table When METHOD=MAD

Figure 66.4 displays the table of location and scale measures when the standardization method is MAD. The location measure is the median, and the scale measure is the median absolute deviation from median. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.06 (32.0/15.5) and is close to the dispersion ratio observed in the previous Schematic Plots.
Figure 66.5. Location and Scale Measures Table When METHOD=IQR

Figure 66.5 displays the table of location and scale measures when the standardization method is IQR. The location measure is the median, and the scale measure is the interquartile range. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.03 (61/30) and is, in fact, the dispersion ratio observed in the previous Schematic Plots.
Figure 66.6. Location and Scale Measures Table When METHOD=ABW

Figure 66.6 displays the table of location and scale measures when the standardization method is ABW. The location measure is the biweight 1-step M-estimate, and the scale measure is the biweight A-estimate. Note that the initial estimate for ABW is MAD. The tuning constant (4) of ABW is obtained by the following steps:

1. For rural scores, the location estimate for MAD is 166.0 and the scale estimate for MAD is 32.0. The maximum of the rural scores is 253 (not shown), and the minimum is 110 (not shown). Thus, the tuning constant needs to be 3 so that it does not reject any observation that has a score between 110 to 253.

2. For urban scores, the location estimate for MAD is 153.0 and the scale estimate for MAD is 15.5. The maximum of the rural scores is 198, and the minimum (also an outlier) is 64. Thus, the tuning constant needs to be 4 so that it rejects the outlier (64) but includes the maximum (198) as an normal observation.

3. The maximum of the tuning constants, obtained in steps 1 and 2, is 4.

Refer to Goodall (1983, Chapter 11) for details on the tuning constant. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.06 (32.0/15.5). It is also close to the dispersion ratio observed in the previous Schematic Plots.

The preceding analysis shows that METHOD=MAD, METHOD=IQR, and METHOD=ABW all provide better dispersion ratios than does METHOD=STD.
You can recompute the standard deviation after deleting the outlier from the original data set for comparison. The following statements create a DATA set NoOutlier that excludes the outlier from the TotalScores data set and invoke PROC STDIZE with METHOD=STD.

```sas
data NoOutlier;
  set totalscores;
  if (total = 64) then delete;
run;

proc stdize data=NoOutlier method=std pstat;
  title2 'after removing outlier, METHOD=STD';
  var total;
  by Type;
run;
```

**Figure 66.7.** After Deleting the Outlier, Location and Scale Measures Table When METHOD=STD

Figure 66.7 displays the location and scale measures after deleting the outlier. The lack of resistance of the standard deviation to outliers is clearly illustrated: if you delete the outlier, the sample standard deviation of urban scores changes from 30.07 to 22.09. The new ratio of the scale of rural scores to the scale of urban scores is approximately 1.90 (41.96/22.09).
Syntax

The following statements are available in the STDIZE procedure.

```
PROC STDIZE < options > ;
   BY variables ;
   FREQ variable ;
   LOCATION variables ;
   SCALE variables ;
   VAR variables ;
   WEIGHT variable ;
```

The PROC STDIZE statement is required. The BY, LOCATION, FREQ, VAR, SCALE, and WEIGHT statements are described in alphabetical order following the PROC STDIZE statement.

**PROC STDIZE Statement**

```
PROC STDIZE < options > ;
```

The PROC STDIZE statement invokes the procedure. You can specify the following options in the PROC STDIZE statement.

**Table 66.1.** Summary of PROC STDIZE Statement Options

</tr>
</tbody>
</table>

These options and their abbreviations are described, in alphabetical order, in the remainder of this section.

**ADD= c**

specifies a constant, c, to add to each value after standardizing and multiplying by the value you specify in the MULT= option. The default value is 0.

**DATA=SAS-data-set**

specifies the input data set to be standardized. If you omit the DATA= option, the most recently created data set is used.

**FUZZ=c**

specifies the relative fuzz factor. The default value is 1E-14. For the OUT= data set, the score is computed as follows:

\[
\text{if } |\text{Result}| < \text{Scale} \times \text{Fuzz}, \text{then } \text{Result} = 0
\]

For the OUTSTAT= data set and the Location and Scale table, the scale and location values are computed as follows:

\[
\text{if } \text{Scale} < |\text{Location}| \times \text{Fuzz}, \text{then } \text{Scale} = 0
\]
Otherwise,

if \(|\text{Location}| < \text{Scale} \times \text{Fuzz}\), then Location = 0

**INITIAL=** *method*

specifies the method for computing initial estimates for the A estimates (ABW, AWA VE, and AHUBER). The following methods are not allowed: INITIAL=ABW, INITIAL=AHUBER, INITIAL=AWAVE, and INITIAL=IN. The default is INITIAL=MAD.

**METHOD=** *name*

specifies the name of the method for computing location and scale measures. Valid values for *name* are as follows: MEAN, MEDIAN, SUM, EUCLEN, USTD, STD, RANGE, MIDRANGE, MAXABS, IQR, MAD, ABW, AHUBER, AWA VE, AGK, SPACING, L, and IN.

For details on these methods, see the descriptions in the “Standardization Methods” section on page 4136. The default is METHOD=STD.

**MISSING=** *method*

**MISSING=** *value*

specifies the method (or a numeric value) for replacing missing values. If you omit the MISSING= option, the REPLACE option replaces missing values with the location measure given by the METHOD= option. Specify the MISSING= option when you want to replace missing values with a different value. You can specify any name that is valid in the METHOD= option except the name IN. The corresponding location measure is used to replace missing values.

If a numeric value is given, the value replaces missing values after standardizing the data. However, you can specify the REPO NLY option with the MISSING= option to suppress standardization for cases in which you want only to replace missing values.

**MULT=** *c*

specifies a constant, *c*, by which to multiply each value after standardizing. The default value is 1.

**NMARKERS=** *n*

specifies the number of markers used when you specify the one-pass algorithm (PCTLMTD=ONEPASS). The value *n* must be greater than or equal to 5. The default value is 105.

**NOMISS**

omits observations with missing values for any of the analyzed variables from calculation of the location and scale measures. If you omit the NOMISS option, all nonmissing values are used.

**NORM**

normalizes the scale estimator to be consistent for the standard deviation of a normal distribution when you specify the option METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING.
**OUT=SAS-data-set**
specifies the name of the SAS data set created by PROC STDIZE. The output data set is a copy of the DATA= data set except that the analyzed variables have been standardized. Note that analyzed variables are those specified in the VAR statement or, if there is no VAR statement, all numeric variables not listed in any other statement. See the section “Output Data Sets” on page 4141 for more information.

If you want to create a permanent SAS data set, you must specify a two-level name. (Refer to “SAS Files” in SAS Language Reference: Concepts for more information on permanent SAS data sets.)

If you omit the OUT= option, PROC STDIZE creates an output data set named according to the DATA_n convention.

**OUTSTAT=SAS-data-set**
specifies the name of the SAS data set containing the location and scale measures and other computed statistics. See the section “Output Data Sets” on page 4141 for more information.

**PCTLDEF=percentiles**
specifies which of five definitions is used to calculate percentiles when you specify the option PCTLMTD=ORD_STAT. By default, PCTLDEF=5.

Note that the option PCTLMTD=ONEPASS implies a specification of PCTLDEF=5. See the section “Computational Methods for the PCTLDEF= Option” on page 4140 for details on this option.

**PCTLMTD=ORD_STAT**

**PCTLMTD=ONEPASS | P2**
specifies the method used to estimate percentiles. Specify the PCTLMTD=ORD_STAT option to compute the percentiles by the order statistics method. The PCTLMTD=ONEPASS option modifies an algorithm invented by Jain and Chlamtac (1985). See the “Computing Quantiles” section on page 4139 for more details on this algorithm.

The PCTLMTD=ONEPASS option modifies an algorithm invented by Jain and Chlamtac (1985). See the “Computing Quantiles” section on page 4139 for more details on this algorithm.

**PCTLPTS= n**
writes percentiles to the OUTSTAT= data set. Values of n can be any decimal number between 0 and 100, inclusive.

A requested percentile is identified by the _TYPE_ variable in the OUTSTAT= data set with a value of Pn. For example, suppose you specify the option PCTLPTS=10, 30. The corresponding observations in the OUTSTAT= data set that contain the 10th and the 30th percentiles would then have values _TYPE_=P10 and _TYPE_=P30, respectively.
PROC STDIZE Statement

PSTAT
displays the location and scale measures.

REPLACE
replaces missing data with the value 0 in the standardized data (this value corresponds to the location measure before standardizing). To replace missing data by other values, see the preceding description of the MISSING= option. You cannot specify both the REPLACE and REONLY options.

REONLY
replaces missing data only; PROC STDIZE does not standardize the data. Missing values are replaced with the location measure unless you also specify the MISSING=value option, in which case missing values are replaced with value. You cannot specify both the REPLACE and REONLY options.

SNORM
normalizes the scale estimator to have an expectation of approximately 1 for a standard normal distribution when you specify the METHOD=SPACING option.

UNSTD
UNSTDIZE
unstandardizes variables when you specify the METHOD=IN(ds) option. The location and scale measures, along with constants for addition and multiplication that the unstandardization is based upon, are identified by the _TYPE_ variable in the ds data set.

The ds data set must have a _TYPE_ variable and contain the following two observations: a _TYPE_ = ‘LOCATION’ observation and a _TYPE_ = ‘SCALE’ observation. The variable _TYPE_ can also contain the optional observations, ‘ADD’ and ‘MULT’; if these observations are not found in the ds data set, the constants specified in the ADD= and MULT= options (or their default values) are used for unstandardization.

See the "OUTSTAT= Data Set" section on page 4141 for details on the statistics that each value of _TYPE_ represents. The formula used for unstandardization is as follows: If the final output value from the previous standardization is calculated as

\[
\text{result} = \text{add} + \text{multiply} \times \frac{\text{original} - \text{location}}{\text{scale}}
\]

\[
\text{original} = \text{scale} \times \frac{\text{result} - \text{add}}{\text{multiply}} + \text{location}
\]

VARDEF= DF
VARDEF= N
VARDEF= WDF
VARDEF= WEIGHT | WGT

specifies the divisor to be used in the calculation of variances. By default, VARDEF=DF. The values and associated divisors are as follows.
BY Statement

BY variables ;

You can specify a BY statement with PROC STDIZE to obtain separate standardization for observations in groups defined by the BY variables.

If your DATA= input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the STDIZE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information on the BY statement, refer to the discussion in SAS Language Reference: Concepts. For more information on the DATASETS procedure, refer to the discussion in the SAS Procedures Guide.

When you specify the option METHOD=IN(ds), the following rules are applied to BY-group processing:

- If the ds data set does not contain any of the BY variables, the entire DATA= data set is standardized by the location and scale measures (along with the constants for addition and multiplication) in the ds data set.
- If the ds data set contains some, but not all, of the BY variables or if some BY variables do not have the same type or length in the ds data set that they have in the DATA= data set, PROC STDIZE displays an error message and stops.
- If all of the BY variables appear in the ds data set with the same type and length as in the DATA= data set, each BY group in the DATA= data set is standardized using the location and scale measures (along with the constants for addition and multiplication) from the corresponding BY group in the ds data set. The BY groups in the ds data set must be in the same order as they appear in the DATA= data set. All BY groups in the DATA= data set must also appear in the ds data set. If you do not specify the NOTSORTED option, some BY groups can appear in the ds data set but not in the DATA= data set; such BY groups are not used in standardizing data.
FREQ Statement

FREQ | FREQUENCY variable;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable name in a FREQ statement. PROC STDIZE treats the data set as if each observation appeared \( n \) times, where \( n \) is the value of the FREQ variable for the observation. Nonintegral values of the FREQ variable are truncated to the largest integer less than the FREQ value. If the FREQ variable has a value that is less than 1 or is missing, the observation is not used in the analysis.

LOCATION Statement

LOCATION variables;

The LOCATION statement specifies a list of numeric variables that contain location measures in the input data set specified by the METHOD=IN option.

SCALE Statement

SCALE variables;

The SCALE statement specifies the list of numeric variables containing scale measures in the input data set specified by the METHOD=IN option.

VAR Statement

VAR | VARIABLES variables;

The VAR statement lists numeric variables to be standardized. If you omit the VAR statement, all numeric variables not listed in the BY, FREQ, and WEIGHT statements are used.

WEIGHT Statement

WGT | WEIGHT variable;

The WEIGHT statement specifies a numeric variable in the input data set with values that are used to weight each observation. Only one variable can be specified.

The WEIGHT variable values can be nonintegers. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero. The WEIGHT variable applies only when you specify the option METHOD=MEAN, METHOD=SUM, METHOD=EUCLEN, METHOD=USTD, METHOD=STD, METHOD=AGK, or METHOD=L.

PROC STDIZE uses the value of the WEIGHT variable \( w_i \), as follows.

The sample mean and (uncorrected) sample variances are computed as

\[
\bar{x}_w = \frac{\sum_i w_i x_i}{\sum_i w_i}
\]
\[ w_{\text{us}}^2 = \sum_i w_i x_i^2 / d \]

\[ s_{\text{ws}}^2 = \sum_i w_i (x_i - \bar{x}_w)^2 / d \]

where \( w_i \) is the weight value of the \( i \)th observation, \( x_i \) is the value of the \( i \)th observation, and \( d \) is the divisor controlled by the VARDEF= option (see the VARDEF= option for details).

PROC STDIZE uses the value of the WEIGHT variable to calculate the following statistics:

- **MEAN**: the weighted mean, \( \bar{x}_w \)
- **SUM**: the weighted sum, \( \sum_i w_i x_i \)
- **USTD**: the weighted uncorrected standard deviation, \( \sqrt{w_{\text{us}}^2} \)
- **STD**: the weighted standard deviation, \( \sqrt{s_{\text{ws}}^2} \)
- **EUCLEN**: the weighted Euclidean length, computed as the square root of the weighted uncorrected sum of squares:
  \[ \sqrt{\sum_i w_i x_i^2} \]

- **AGK**: the AGK estimate. This estimate is documented further in the ACECLUS procedure as the METHOD=COUNT option. See the discussion of the WEIGHT statement in Chapter 16, “The ACECLUS Procedure,” for information on how the WEIGHT variable is applied to the AGK estimate.

- **L**: the \( L_p \) estimate. This estimate is documented further in the FASTCLUS procedure as the LEAST= option. See the discussion of the WEIGHT statement in Chapter 28, “The FASTCLUS Procedure,” for information on how the WEIGHT variable is used to compute weighted cluster means. Note that the number of clusters is always 1.

## Details

### Standardization Methods

The following table lists standardization methods and their corresponding location and scale measures available with the METHOD= option.
Table 66.2. Available Standardization Methods

</tbody>
</table>

For METHOD=ABW(\(c\)), METHOD=AHUBER(\(c\)), or METHOD=AWAVE(\(c\)), \(c\) is a positive numeric tuning constant.

For METHOD=AGK(\(p\)), \(p\) is a numeric constant giving the proportion of pairs to be included in the estimation of the within-cluster variances.

For METHOD=SPACING(\(p\)), \(p\) is a numeric constant giving the proportion of data to be contained in the spacing.

For METHOD=L(\(p\)), \(p\) is a numeric constant greater than or equal to 1 specifying the power to which differences are to be raised in computing an L(\(p\)) or Minkowski metric.

For METHOD=IN(\(ds\)), \(ds\) is the name of a SAS data set that meets either one of the following two conditions:

- contains a _TYPE_ variable. The observation that contains the location measure corresponds to the value _TYPE_ = ’LOCATION’ and the observation that contains the scale measure corresponds to the value _TYPE_ = ’SCALE’. You can also use a data set created by the OUTSTAT= option from another PROC STDIZE statement as the \(ds\) data set. See the section “Output Data Sets” on page 4141 for the contents of the OUTSTAT= data set.
- contains the location and scale variables specified by the LOCATION and SCALE statements.

PROC STDIZE reads in the location and scale variables in the \(ds\) data set by first looking for the _TYPE_ variable in the \(ds\) data set. If it finds this variable, PROC
STDIZE continues to search for all variables specified in the VAR statement. If it does not find the _TYPE_ variable, PROC STDIZE searches for the location variables specified in the LOCATION statement and the scale variables specified in the SCALE statement.

For robust estimators, refer to Goodall (1983) and Iglewicz (1983). The MAD method has the highest breakdown point (50%), but it is somewhat inefficient. The ABW, AHUBER, and AWAVE methods provide a good compromise between breakdown and efficiency. The L(p) location estimates are increasingly robust as p drops from 2 (corresponding to least squares, or mean estimation) to 1 (corresponding to least absolute value, or median estimation). However, the L(p) scale estimates are not robust.

The SPACING method is robust to both outliers and clustering (Jannsen et al. 1995) and is, therefore, a good choice for cluster analysis or nonparametric density estimation. The mid-minimum spacing method estimates the mode for small p. The AGK method is also robust to clustering and more efficient than the SPACING method, but it is not as robust to outliers and takes longer to compute. If you expect g clusters, the argument to METHOD=SPACING or METHOD=AGK should be \( \frac{1}{g} \) or less. The AGK method is less biased than the SPACING method for small samples. As a general guide, it is reasonable to use AGK for samples of size 100 or less and SPACING for samples of size 1000 or more, with the treatment of intermediate sample sizes depending on the available computer resources.

**Computation of the Statistics**

Formulas for statistics of METHOD=MEAN, METHOD=MEDIAN, METHOD=SUM, METHOD=USTD, METHOD=STD, METHOD=RANGE, and METHOD=IQR are given in the chapter on elementary statistics procedures in the *SAS Procedures Guide*.

Note that the computations of median and upper and lower quartiles depend on the PCTLMTD= option.

The other statistics listed in Table 66.2, except for METHOD=IN, are described as follows:

- **EUCLLEN**
  
  Euclidean length.
  
  \[ \sqrt{\sum_{i=1}^{n} x_i^2} \]
  
  where \( x_i \) is the \( i \)th observation and \( n \) is the total number of observations in the sample.

- **L(p)**
  
  Minkowski metric. This metric is documented as the LEAST=p option in the PROC FASTCLUS statement of the FASTCLUS procedure (see Chapter 28, “The FASTCLUS Procedure,”).

  If you specify METHOD=L(p) in the PROC STDIZE statement, your results are similar to those obtained from PROC FASTCLUS if you specify the LEAST=p option with MAXCLUS=1 (and use the default values of the MAXITER= option). The difference between the two types of calculations concerns the maximum number of iterations. In PROC STDIZE, it is a criteria for convergence on
all variables; In PROC FASTCLUS, it is a criteria for convergence on a single variable.

The location and scale measures for \( L(p) \) are output to the OUTSEED= data set in PROC FASTCLUS.

**MIDRANGE**

\[
\frac{\text{maximum} + \text{minimum}}{2}
\]

**ABW(c)**

**AHUBER(c)**

**AWAVE(c)**

**AGK(p)**

The noniterative univariate form of the estimator described by Art, Gnanadesikan, and Kettenring (1982).

The AGK estimate is documented in the section on the METHOD= option in the PROC ACECLUS statement of the ACECLUS procedure (also see the “Background” section on page 388 in Chapter 16, “The ACECLUS Procedure,” ). Specifying METHOD=AGK(p) in the PROC STDIZE statement is the same as specifying METHOD=COUNT and P=p in the PROC ACECLUS statement.

**SPACING(p)**

The absolute difference between two data values. The minimum spacing for a proportion \( p \) is the minimum absolute difference between two data values that contain a proportion \( p \) of the data between them. The mid minimum-spacing is the mean of these two data values.

### Computing Quantiles

**PROC STDIZE**

PROC STDIZE offers two methods for computing quantiles: the one-pass approach and the order-statistics approach (like that used in the UNIVARIATE procedure).

The one-pass approach used in PROC STDIZE modifies the \( P^2 \) algorithm for histograms proposed by Jain and Chlamtac (1985). The primary difference comes from the movement of markers. The one-pass method allows a marker to move to the right (or left) by more than one position (to the largest possible integer) as long as it does not result in two markers being in the same position. The modification is necessary in order to incorporate the FREQ variable.

You may obtain inaccurate results if you use the one-pass approach to estimate quantiles beyond the quartiles (that is, when you estimate quantiles \( < P_{25} \) or \( > P_{75} )\). A large sample size (10,000 or more) is often required if the tail quantiles (quantiles \( \leq P_{10} \) or \( \geq P_{90} \) ) are requested. Note that, for variables with highly skewed or heavy-tailed distributions, tail quantile estimates may be inaccurate.
The order-statistics approach for estimating quantiles is faster than the one-pass method but requires that the entire data set be stored in memory. The accuracy in estimating the quantiles is comparable for both methods when the requested percentiles are between the lower and upper quartiles. The default is PCTLMTD=ORD_STAT if enough memory is available; otherwise, PCTLMTD=ONEPASS.

**Computational Methods for the PCTLDEF= Option**

You can specify one of five methods for computing quantile statistics when you use the order-statistics approach (PCTLMTD=ORD_STAT); otherwise, the PCTLDEF=5 method is used when you use the one-pass approach (PCTLMTD=ONEPASS).

Let \( n \) be the number of nonmissing values for a variable, and let \( x_1, x_2, \ldots, x_n \) represent the ordered values of the variable. For the \( t \)th percentile, let \( p = t/100 \). In the following definitions numbered 1, 2, 3, and 5, let

\[
np = j + g
\]

where \( j \) is the integer part and \( g \) is the fractional part of \( np \). For definition 4, let

\[
(n + 1)p = j + g
\]

Given the preceding definitions, the \( t \)th percentile, \( y \), is defined as follows:

- **PCTLDEF=1** weighted average at \( x_{np} \)
  \[
y = (1 - g)x_j + gx_{j+1}
\]
  where \( x_0 \) is taken to be \( x_1 \)
